The acoustic cloaking theory of Norris [Proc. R. Soc. London, Ser. A 464, 2411–2434 (2008)] permits considerable freedom in choosing the transformation $f$ from physical to virtual space. The standard process for defining cloak materials is to first define $f$ and then evaluate whether the materials are practically realizable. In this paper, this process is inverted by defining desirable material properties and then deriving the appropriate transformations which guarantee the cloaking effect. Transformations are derived which result in acoustic cloaks with special properties such as (1) constant density, (2) constant radial stiffness, (3) constant tangential stiffness, (4) power-law density, (5) power-law radial stiffness, (6) power-law tangential stiffness, and (7) minimal elastic anisotropy. © 2012 Acoustical Society of America. I. INTRODUCTION

“Acoustic cloaking” refers to making an object invisible to sound waves. This is achieved by enclosing the object of interest with an acoustic cloak which guides waves around the object. The cloak leaves the wave-field outside the cloak indistinguishable from the wave-field without the object present. The phenomenon of cloaking is not restricted to acoustics but can occur for different types of waves such as electromagnetic waves, elastic waves, and in a more exotic example, quantum mechanical systems. We restrict our attention here to acoustic cloaking, and specifically pentamode acoustic cloaking for which the density is isotropic. The reader is referred to the review articles by Bryan and Leise and Greenleaf et al. for a comprehensive review of different types of cloaking, its historical development and relation to previous work in inverse problems. A review dedicated to acoustic cloaking and transformation acoustics is provided by Chen and Chan.

Initial work in acoustic cloaking was based on transformation optics as developed by Cummer et al. mapped the 2D acoustic equations in a fluid to the single polarization Maxwell’s equations, while Chen et al. mapped the 3D acoustic equation to the direct current conductivity equation in 3D. Cummer et al. derived a formulation for 3D acoustic cloaking starting from scattering theory. These formulations achieved acoustic cloaking using anisotropic density and isotropic stiffness. Norris provided a formulation of acoustic cloaking using both anisotropic inertia and stiffness, and as a special case, derived a formulation using isotropic density and anisotropic stiffness.

The acoustic cloaking theory of Norris involves mapping the physical space to the virtual space using the transformation $f$ as illustrated in Fig. 1. The material properties of the cloak can be obtained by choosing the transformation $f$ and using Eq. (3) to compute the material properties. In practice, however, the properties obtained may not be useful because they are unattainable. In this paper, we derive special forms of $f$ which may result in physically realizable cloaking metamaterials, which are composite materials whose macroscopic acoustic properties are controlled by engineering their microstructure. The design and fabrication of such acoustic metamaterials is possible because of recent advances in material science and engineering. Cloaking metamaterials may have spatially varying anisotropic density and stiffness. We restrict our attention here to spatially varying material properties with isotropic density and anisotropic stiffness because Norris showed that anisotropic density implies that the acoustic cloak has infinite mass. He presented an alternative acoustic cloaking formulation involving pentamode materials which have isotropic density and a special type of anisotropic stiffness. Since cloaking is achieved with anisotropic stiffness as opposed to density, it is expected to have frequency independent behavior in theory. In practice, however, the behavior is expected to be only extremely wideband or weakly frequency dependent because of frequency limitations arising from the following.

The size of the virtual cloak radius $\delta$ as compared to the wavelength of the incident acoustic wave $\lambda$. Cloaking is ineffective for incident acoustic waves whose wavelength is of the same order as the virtual cloak radius $\delta$.

The length scale of periodic structures present in the composite material used to fabricate the pentamode material.

An intrinsic frequency dependence in the properties of the composite material.

The paper is organized as follows. Section II provides a short review of the pentamode acoustic cloaking theory. Next, in Sec. III, we derive transformations $f$ which yield specialized spatial distributions of material properties, namely, (1) constant density, (2) constant radial stiffness, (3) constant tangential stiffness, and explain the wave-propagation with ray-tracing. Such distributions may be simple to manufacture and may also help in evaluating the

feasibility of manufacturing material properties on Ashby charts, as in Ref. 12. We note that in related work, Cummer13 has derived transformations for electromagnetic cloaking which yield constant magnetic permittivity ε. In Sec. IV we derive transformations which yield (1) power-law density, (2) power-law radial stiffness, and (3) power-law tangential stiffness. In Sec. V, we derive a distribution of elastic properties that minimizes the elastic anisotropy.

II. REVIEW OF ACOUSTIC CLOAKING USING PENTAMODE MATERIALS

Acoustic cloaking relies on a transformation from an undeformed or original domain Ω to a current (deformed) domain ω which is given by the point-wise deformation X ∈ Ω → x ∈ ω. Using notation from the theory of finite elasticity, the deformation gradient is defined F = ∇xX, or in component form Fμ = ∂xμ/∂Xλ. The Jacobian of the deformation is J = det F, or in terms of volume elements in the two configurations, J = det dV. The polar decomposition is F = VR, where R is proper orthogonal (RR′ = RR′ = I, det R = 1) and the left stretch tensor V is the positive definite solution of V2 = B where B is the left Cauchy-Green or Finger tensor B = FF′.

For a given transformation the cloaking material is not unique.14 For instance, the inertial cloak [Eq. (2.8)]14 is defined by the density tensor ρ = ρ0/B−1 and bulk modulus K = K0J. At the other end of the spectrum of possible materials is the pentamode cloak with isotropic density, which can be chosen if the deformation satisfies the property14 (Lemma 4.3) that there is a function h(x) for which div hV = 0. This is the case for radially symmetric deformations in 2D and 3D, the cylinder and sphere, respectively. The pentamode material is then [Eq. (4.8)]14 ρ = ρ0J−1, K = K0J, S = J−1V, where the fourth order elasticity tensor is C = KS ⊗ S.

Radially symmetric deformations in 2D and 3D are defined by R−1X = r−1x where R = |X|, r = |x|. If we let R = f(r), then the inverse mapping is defined as X = f(r)r−1x. In this case we can identify a “radial bulk modulus” and an orthogonal bulk modulus

\[ K_r = C_{rrr} = K_0J^{-1}B_{rr}, \quad K_\perp = K_0J^{-1}B_{\theta\theta}, \]

where θ denotes a direction orthogonal to the radial direction.

The requirements on the transformation generator f(r) admit an infinity of functions. In this paper, we will take advantage of this fact to design transformations which result in desirable material properties. One familiar transformation, used frequently in acoustic cloaking work, is shown in Fig. 1. Some examples from the infinite family of permissible transformations are

\[ R = f(r) = \begin{cases} \frac{b - r}{b - a} & r < a \\ b & r \geq a \end{cases} \]

\[ f^{-1}(R) = \begin{cases} \frac{(b - \delta) r - b (a - \delta)}{b - a} & R < 1 \\ \delta & R \geq 1 \end{cases} \]

where b, a, and δ are the outer radius of the cloak, the inner radius of the cloak, and the virtual cloak radius, as shown in Fig. 1. The linear transformation (2a) is known as the KSVW mapping from Ref. 14 in which it was first used extensively in this form. Figure 2(a) shows rays passing through a KSVW cloak. The power law mapping (2b) yields constant Kr for the inertial cloak and constant K for the pentamode cloak in 2D. As we will see below, the transformation (2c) yields constant K for the inertial cloak or constant ρ for the pentamode cloak (see Figs. 3–5).

III. TRANSFORMATIONS YIELDING CONSTANT MATERIAL PROPERTY DISTRIBUTIONS

In this section we determine the transformations f that yield constant spatial distributions of material properties. We consider a constant distribution of ρ in Sec. III A, constant K, in Sec. III B, and constant K⊥ in Sec. III C, respectively. Both 2D and 3D cases are considered. The conditions for feasibility are summarized in Table I.

The density ρ (isotropic), the radial stiffness K, and the tangential stiffness K⊥ for a pentamode cloak surrounded by an isotropic fluid with density ρ0 and bulk modulus K0 satisfy the following relations:

\[ K_r(r) = K_0 \left( \frac{r}{r_0} \right)^d, \quad K_\perp(r) = K_0 \left( \frac{r}{r_0} \right)^{d-3}, \]

\[ \rho(r) = \rho_0 \left( \frac{r}{r_0} \right)^d. \]

Our procedure to determine f consists of treating Eq. (3) as differential equations for f with the material properties (ρ, Kn, K⊥) known. Having determined f we will prove that it satisfies the necessary conditions f > 0, f′ > 0 for r ∈ [a, b], the existence of b such that f(b) = b, and the existence of δ such that f(a) = δ ≪ a.

Gokhale et al.: Special transformations for acoustic cloaking
We remark that Eq. (3) is consistent with the connection between the three parameters which is independent of the transformation:

\[
K_0^{-d_1}d_{K_0}^{d_2-1} = \left(\rho/\rho_0\right)^{d_2-2}.
\]

Equation (3) also implies that at the edge of the cloak, the cloak is impedance matched in the radial direction but not in the tangential direction:

\[
Z_r(r) \equiv \sqrt{K_r/\rho} \Rightarrow Z_r(b) = \sqrt{K_0\rho_0} = Z_0,
\]

\[
Z_\perp(r) \equiv \sqrt{K_\perp/\rho} \Rightarrow Z_\perp(b) = Z_0f(b).
\]

In contrast, at the edge of the cloak, the wave speeds are matched in the tangential direction, but not in the radial direction:

\[
c_r(r) \equiv \sqrt{K_r/\rho} \Rightarrow c_r(b) = c_0f(b),
\]

\[
c_\perp(r) \equiv \sqrt{K_\perp/\rho} \Rightarrow c_\perp(b) = c_0.
\]

A. Transformations yielding constant cloak density \(\rho\)

We assume that we are given the cloak geometry \(b > a > 0\), and using Eq. (3) and \(\rho(r) = \rho_0\), a constant, we determine \(f\) and prove that \(f > 0, f' > 0\) for \(r \in (a, b)\). Solving (3) for \(f\) yields
\[ f = \left[ b^d + \frac{\rho_c}{\rho_0} \left( (d^d - b^d) \right) \right]^{1/d}, \]  

and differentiating implies \( f' > 0 \) for \( \rho > 0 \), showing that \( f \) is monotonically increasing. Since \( f(a) = \delta > 0, f > 0 \in (a, b) \). Enforcing \( \delta = f(a) < a \) yields \( \rho_c > \rho_0 \). This result makes physical sense because the deformation \( f^{-1} \) compresses the volume of fluid into a smaller volume. \( K_r, K_\perp \) are determined by using \( f \) in Eq. (3) and are given by

\[ K_r = K_0 \left( \frac{f}{r} \right)^{2(d-1)}, \quad K_\perp = K_0 \left( \frac{\rho_c}{\rho_0} \right)^2 \left( \frac{f}{r} \right)^2. \]  

Similarly \( \delta \) and its sensitivity can be determined by

\[ \delta = \left[ b^d + \frac{\rho_c}{\rho_0} \left( (d^d - b^d) \right) \right]^{1/d}, \quad \frac{\partial \delta}{\partial \rho_c} = \frac{d^d - b^d}{\rho_0 d \delta^{d-1}} < 0. \]  

Finally, note that, \( K_r \propto \delta^{2(d-1)} \) and \( K_\perp \propto \delta^{-2} \) in 3D this implies a very strong decrease in \( K_r \) with \( \delta \).

We note that rays in the cloak are straight lines in deformed space.\(^{11}\) This allows us to trace the rays for the constant density cloak by deforming the straight rays corresponding to a plane wave traveling through a homogeneous medium by the inverse transformation \( f^{-1} \). Ray-tracing results
are shown in Fig. 2(b), from which we can see that the rays curve gently in the outer region of the cloak and sharply close to the inner radius. In our experience, the smooth nature of this propagation makes it easy for this to be simulated with standard linear finite elements.\textsuperscript{15}

### B. Transformations yielding constant radial stiffness $K_r$

We formulate the problem by assuming that we are given $a > \delta > 0$ and $K_r$ constant. As before, start with the expression for $K_r$ from Eq. (3), and treat it as an ordinary differential equation for $f$ and get

$$\int \frac{f'}{f^{d-1}} dr = -\int \frac{d}{K_r} f \frac{K_r}{K_0} dr.$$  (10)

The solution is different for 2D and 3D and is determined separately in the next two subsections

#### 1. Transformation yielding constant $K_r$ in 2D

The transformation $f$ in 2D can be determined by solving Eq. (10) to get

$$f = b \left( \frac{r}{b} \right)^{K_0/K_r}, \quad f' = \frac{K_0 f}{K_r r} > 0.$$  (11)

The cloak parameters then follow from Eq. (3) as

$$\rho = \rho_0 \frac{K_0}{K_r} \left( \frac{r}{b} \right)^{2(K_0/K_r-1)}, \quad K_0 = K_0 \frac{\ln a/b}{\ln \delta/b},$$

$$\delta = a \left( \frac{r}{b} \right)^{K_0/K_r-1} \frac{\ln a/b}{K_r}, \quad \rho = \rho_0 (\delta/a)^2 > 0.$$  (12)

We prove that given $a > \delta > 0$, it is possible to find $b$ such that $b > a > \delta > 0$ for $K_r = \text{const} > 0$. Since $\delta/a < 1$ and $a < b$, the exponent $K_0/K_r - 1$ in Eq. (12) must be positive to ensure $b > a$, i.e., $0 < K_r < K_0$ must hold for constant $K_r$ cloaks in 2D. This shows that the cloak outer radius is greater than the inner radius, making the cloak physically realistic.

This case is of interest because the only parameter that varies with $r$ is the density. At the outer radius $\rho(b) = \rho_0 (K_0/K_r) > \rho_0$, and the value at the inner radius is $\rho(a) = \rho_0 (\delta/a)^2$.

The rays for a constant $K_r$ cloak in 2D are shown in Fig. 2(c). Unlike the rays for the constant density cloak shown in Fig. 2(b), the rays for constant stiffness curve sharply at the outer surface of the cloak. In our experience, the propagation of waves near the surface is extremely hard to capture with standard linear, time-domain, finite elements, possibly due to sharp change in the direction of propagation. The required element density is in the order of hundreds of elements per shortest wavelength. This is contrast to the rule of thumb in transient, explicit finite element analysis in which typically sixteen elements per shortest wavelength are used.

2. Transformation yielding constant $K_r$ in 3D

Treating Eq. (10) with $d = 3$ as a differential equation for $f$ with $K_r$ known and constant, gives

$$ f = \left[1 + \frac{K_0}{K_r} \left(1 - \frac{1}{b^2}ight)\right]^{-1} \quad \text{and} \quad f' = \frac{K_0}{K_r} \left(\frac{f}{r}\right)^2 > 0. \quad (13) $$

Using the above definition of $f$ in Eq. (3) we get

$$ \rho = \rho_0 \left(\frac{bK_r}{bK_0 + r(K_r - K_0)}\right)^4, \quad (14a) $$

$$ K_{\perp} = K_r \left(\frac{bK_0}{bK_0 + r(K_r - K_0)}\right)^2, \quad (14b) $$

$$ \delta = f(a) = \frac{a b K_r}{bK_0 + a(K_r - K_0)}. \quad (14c) $$

We now prove that under certain conditions it is possible to find $b$ such that $b > a > \delta > 0$, meaning that the cloak outer radius is greater than the cloak inner radius. As a consequence we prove that $f > 0$. We start by rewriting Eq. (14c) as

$$ \frac{b}{a} = \left(\frac{K_0}{K_r} - 1 \right) \left(\frac{K_0}{K_r} - \frac{a}{\delta}\right). \quad (15) $$

To ensure $b/a > 1$, we require $K_r < K_0(\delta/a)$. Since, $f' > 0 \in (a, b)$ and $f(a) = \delta > 0$, it follows that $f$ is monotonic in the interval $(a, b)$ and therefore $f > 0 \in (a, b)$. Note that, if $\delta < a \Rightarrow K_r < K_0$. Since $K_{\perp} = K_0^2/K_r$, this means $K_{\perp} > K_r$. Thus, to ensure a small scattering cross section we need a material which is very stiff in one direction ($\perp$) as compared to the other ($r$). We expect that such a material will require careful engineering, and such practical constraints may restrict the amount of reduction in the scattering cross section that can be achieved.

C. Transformations with constant tangential stiffness $K_{\perp}$

1. Transformations yielding constant $K_{\perp}$ in 2D

In two dimensions, constant $K_{\perp}$ is the same as constant $K_r$ (which was previously considered), because $K_rK_{\perp} = K_0^2$ in 2D.

2. Transformations yielding constant tangential stiffness in 3D

We formulate the problem as follows. We consider that we are given $a > \delta > 0$. We need to find $b > a > \delta > 0$ such that $f(a) = \delta, f(b) = b, b > a$. We treat Eq. (3) as a differential equation for $f$ and obtain after using the boundary condition $f(a) = \delta$,

$$ f(r) = \delta + \frac{K_0}{K_r} (r - a) > 0 \quad \text{and} \quad f' = \frac{K_0}{K_r} > 0, \quad (16) $$

for $r > a$. Using $b = f(b) > a$ yields the condition $K_{\perp} > K_0$. The constant $K_{\perp}$ cloak in three dimensions is characterized by $f$ of Eq. (16) and

$$ \rho = \rho_0 \left(\frac{bK_r}{bK_0 + r(K_r - K_0)}\right)^4, \quad (17) $$

Note that this is the same transformation as the KSVW transformation in Eq. (2).

IV. TRANSFORMATIONS YIELDING POWER LAW PROPERTY VARIATION IN 2D

We now consider more complicated spatial distributions for the material properties, namely, power law variations of density, radial stiffness tangential stiffness, and a case in which density is proportional to stiffness. This treatment is restricted to two dimensions.

A. Transformations yielding power law density

Consider the following strategy: Given $b > a > \delta > 0$, $\alpha \neq 0$, we determine $\rho(a) = \rho_a$ that ensures $f(b) = b$ and prove that $\rho_a > 0$. The power law for density we consider is as follows:

$$ \rho(r) = \rho_a \left(\frac{r}{a}\right)^{2x}, \quad (18) $$

where the latter is a consequence of Eq. (3). The cases $\alpha = -2$ and $\alpha = -2$ need to be considered separately. To summarize, the power law density cloak in two dimensions is characterized by Eq. (18), with

$$ f^2 = \delta^2 + 2\rho_a \frac{(r^{x+2} - a^{x+2})}{\rho_0 a^\alpha (x + 2)}, \quad \text{for} \quad \alpha \neq -2, \quad (19) $$

$$ \rho_a = \rho_0 \frac{(x + 2) a^\alpha (b^2 - \delta^2)}{2 (b^{x+2} - a^{x+2})}, $$

and

$$ f^2 = \delta^2 + 2 a^\alpha \rho_a \ln \left(\frac{r}{a}\right), \quad \text{for} \quad \alpha = -2, \quad (20) $$

$$ \rho_a = \rho_0 \frac{(b^2 - \delta^2)}{2 a^\alpha \ln \frac{b}{a}}, $$

and in both cases,

$$ f' = \frac{r^{x+2} \rho_0}{a^\alpha \rho_0}, \quad K_r = K_0 \rho_0 a \rho_0 r^{x+2}. \quad (21) $$

Note that the $\alpha = 0$ corresponds to the special case of constant density in 2D, considered in Sec. III A. To prove $\rho_a > 0$ for $\alpha \neq -2$, consider the two cases $\alpha > -2$ and $\alpha < 0$. In the first case we have, $b^{x+2} > a^{x+2}$, and therefore $\rho_a > 0$. In the second case, we have, $b^{x+2} > a^{x+2}$. In addition, $\alpha > 0$. We need to consider Eq. (21) for $b$ can be used to prove $f^2 > 0$, and choosing the positive root, we get $f > 0$. The positivity of $f'$ follows. A similar analysis can be performed for $\alpha = -2$. The rays resulting from this
power law density transformation are shown in Figures 4 and 5, respectively.

**B. Transformations yielding power law radial stiffness $K_r$**

Here, we consider the following power law for $K_r$

$$K_r(r) = K_a \left( \frac{r}{a} \right)^{2}, \quad a \neq 0.$$  

(22)

The case $a = 0$ (constant $K_a$) was considered in Sec. III B. Given $b > a > \delta$, $a \neq 0$, we find what value of $K_a$ ensures that $f(b) = b$. We then prove this $K_a > 0$. Using Eqs. (3) and (22) plus the boundary conditions $f(a) = \delta$ and $f(b) = b$, we get

$$f = \delta \exp \left\{ \frac{K_0}{K_a} \left( 1 - \left( \frac{a}{r} \right)^{x} \right) \right\},$$  

(23a)

$$f' = f \frac{K_0}{K_a} \left( \frac{a}{r} \right)^{x+1},$$  

(23b)

$$K_a = \frac{K_0}{x \ln \left( \frac{b}{\delta} \right)} \left( 1 - \left( \frac{a}{b} \right)^{x} \right),$$  

(23c)

$$\rho = \rho_0 \frac{f^2 K_0}{r} \left( \frac{a}{r} \right)^{x+1},$$  

(23d)

each of which is clearly positive. The rays resulting from this power law radial stiffness transformation are shown in Figure 6.

**C. An acoustic concentrator**

Motivated by the form of Eq. (23a), we consider the transformation $r = b(R/b)^{10}$ or equivalently, $R = f(r) = b(r/b)^{1/10}$, yielding the rays shown in Fig. 6. The focus of the rays can be made arbitrarily tight. The process can also be reversed: one can place a source at the focus and convert a cylindrical wavefront generated by a point source into a plane wavefront. Similar work on designing acoustic concentrators using transformation acoustics has been recently reported in Wang et al. Previousely, Rahm et al. reported the design of electromagnetic concentrators.

**D. Transformations yielding power law tangential stiffness**

In two dimensions, this is equivalent to power law $K_r$, because $K_\perp = K_0^2 / K_r$.

**E. Transformations yielding proportional density and radial stiffness**

Since density is usually associated with stiffness, we consider a power law linking density with stiffness in the radial direction. This power law is defined as

$$K_r = \beta \rho^\alpha,$$  

(24)

for $\alpha, \beta (\alpha > 0)$ constant. Using the pentamode relations (3) for $K_r$ and $\rho$ in the above equation, we get a differential equation for $f$

$$f^{\delta-1} f' = \omega' r^{\delta-1},$$  

(25)

where

$$\lambda = \frac{zd + 2 - d}{\alpha + 1}, \quad \omega = \left( \frac{K_0}{\beta \rho_0^\alpha} \right)^{1/(\alpha+1)\lambda}.$$  

(26)
In this case, Eq. (25) yields
\[ f(r) = \left( \delta^\prime + \omega^\prime (r^\prime - a^\prime) \right)^{1/\lambda}. \] (27)

This equation is not consistent with the constraint that \( f(b) = b > a \) if \( \lambda < 0 \), in general. For \( \lambda > 0 \), setting \( f(b) = b \) yields
\[ \delta = \left( b^\prime - \omega^\prime (b^\prime - a^\prime) \right)^{1/\lambda}. \] (28)

Requiring that \( 0 < \delta < a \) implies the a range of possible values for \( \beta \). The special case of \( \lambda = 0 \), i.e., \( \alpha = (d-2)/3 \), needs to be distinguished. In 2D, this means \( \alpha = 0 \) and therefore \( K_r = \text{const} \), and is therefore not interesting. In 3D, this implies, \( \alpha = 1/3 \), and Eq. (25) can be integrated to give a power law solution for \( f(r) \),
\[ f = b \left( \frac{r}{b} \right)^{\mu}, \quad \mu = \left( \frac{K_0}{v_0} \right)^{3/4} \left( d = 3, \alpha = \frac{1}{3} \right). \] (29)

In this case, \( \delta = b(a/b)^\mu \), which is clearly positive, satisfies the constraint \( \delta < a \) only if \( \mu > 1 \) or, equivalently, \( \beta < K_0/v_0^{1/3} \), setting an upper limit on \( \beta \).

In summary, Eq. (24) has cloak-like solutions for \( \alpha \geq 0 \) in 2D, and \( \alpha \geq 1/3 \) in 3D, with associated limits on the possible range in value of the parameter \( \beta \).

V. TRANSFORMATIONS YIELDING MINIMAL ELASTIC ANISOTROPY

Here, we consider acoustic cloaks which have minimal elastic anisotropy in a certain sense. We are motivated by the fact that extremely anisotropic materials are hard to design and manufacture. Minimizing anisotropy therefore may lead to a practical cloak. We begin by defining two measures of anisotropy in equation (31) and prove that only one of them yields physically meaningful transformations.

A. Optimal transformations in cylindrical cloaks

We define the following parameter to be a local measure of the anisotropy in the cloak:
\[ \gamma = \alpha + \frac{1}{\alpha}, \quad \text{where} \quad \alpha = \frac{c_r}{c_\perp}. \] (30)

This is the same anisotropy parameter introduced in Ref. 18. It can be shown that the minimum value of Eq. (30) is 2 and it occurs for \( \alpha = 1 \), i.e., when there is no anisotropy. Based on Eq. (30) we introduce two global measures of cloak anisotropy,
\[ \gamma_1 = V_\omega^{-1} \int_\Omega \gamma \, dv, \quad \gamma_2 = V_\Omega^{-1} \int_\Omega \gamma \, dv, \] (31)

where \( V_\omega, V_\Omega \) are the volumes (areas) in the physical and virtual domains, respectively. It follows from Eq. (1) and the identity (4) for \( d = 2 \) \( (K_0^\perp = K_r^\perp) \) that
\[ J^{-1} \text{tr } B = \frac{K_r}{K_0} + \frac{K_\perp}{K_0} = \sqrt{\frac{K_r}{K_\perp}} + \frac{\sqrt{K_\perp}}{\sqrt{K_r}} = \gamma. \] (32)

Similarly,
\[ J \text{ tr } B^{-1} = \frac{K_0}{K_r} + \frac{K_\perp}{K_r} = \sqrt{\frac{K_\perp}{K_r}} + \frac{\sqrt{K_r}}{\sqrt{K_\perp}} = \gamma. \] (33)

Based on the identities (32) and (33), it follows that
\[ \gamma_1 = V_\omega^{-1} \int_\omega \text{tr } B^{-1} \, dv = V_\omega^{-1} \int_\omega \frac{\partial X_i}{\partial x_j} \frac{\partial x_i}{\partial X_j} \, dv, \] (34a)
\[ \gamma_2 = V_\Omega^{-1} \int_\Omega \text{tr } B \, dv = V_\Omega^{-1} \int_\Omega \frac{\partial x_i}{\partial X_j} \frac{\partial x_i}{\partial X_j} \, dv. \] (34b)

The parameter \( \gamma_1 \) is therefore the average in the current configuration of the sum of the principal stretches of the mapping from the original (virtual) domain. Conversely, \( \gamma_2 \) is the average in the original configuration of the sum of the principal stretches of the inverse mapping from the current (spatial) domain.

The global anisotropy measures \( \gamma_1 \) and \( \gamma_2 \) are minimized by the Euler–Lagrange equations. Consider \( \gamma_1 \), then assuming \( \omega \) is fixed, we have
\[ \delta \gamma_1 = 2 V_\omega^{-1} \int_\omega \frac{\partial X_i}{\partial x_j} \frac{\partial (\partial x_i)}{\partial X_j} \, dv \\
= \frac{2}{V_\omega} \left( \int_{\partial \omega} \frac{\partial x_i}{\partial x_j} \frac{\partial x_i}{\partial x_j} - \int_\omega \frac{\partial^2 x_i}{\partial x_j \partial x_l} \frac{\partial x_i}{\partial x_l} \, dv \right). \]

The surface integral vanishes because, by assumption, the value of \( X \) on the boundary of \( V_\omega \) is constant (in fact \( X = x \) is required on \( \partial \omega \)), and therefore we deduce
\[ \min \gamma_1 \iff \nabla^2 X = 0 \quad \text{in} \ \omega, \] (35a)
\[ \min \gamma_2 \iff \nabla^2 x = 0 \quad \text{in} \ \Omega. \] (35b)

It is interesting to note that these equations are satisfied by conformal transformations, a large class of potential transformations. Here, however, we restrict attention to purely radial transformations.

Consider (35a) first. Assuming the inverse mapping \( X = f(r)r^{-1}x \) then it is straightforward to show that \( \nabla^2 X = (r f'(f)^{-1}) - f(f)^{-1} \nabla^2 x \), and Eq. (35a) is satisfied if \( f = Ar + Br^{-1} \), for constants \( A \) and \( B \). As before, we assume the cloak occupies \( R \in [\delta, b] \), \( r \in [a, b] \) with \( 0 < \delta < a < b \).

The constants are then found from the conditions \( f(a) = \delta \) and \( f(b) = b \), yielding
\[ f(r) = (b^2 - a^2)^{-1} \left[ (b^2 - a^2) r - (a - \delta) b^2 \frac{q}{r} \right]. \] (36)

The same result can be found by noting that the anisotropy parameter of Eq. (34a) reduces for radially symmetric transformations to

Gokhale et al.: Special transformations for acoustic cloaking
\[
\gamma_1 = \frac{d}{b^d - a^d} \int_a^b \left[ (f')^2 + (d-1) \left( \frac{f'}{f} \right)^2 \right] r^{d-1} dr, \tag{37}
\]

for \(d=2\) or \(d=3\). The minimizer satisfies the Euler–Lagrange equation \(r^2 - d(f^{d-1})' - (d - 1)f = 0\), which for \(d=2\) gives Eq. \(36\). In the same way, we find that Eq. \(35b\) is satisfied if \(r = AR + BR^{-1}\), for constants \(A\) and \(B\). The end conditions \(r(\delta) = a\) and \(r(b) = b\) imply that the transformation which minimizes \(\gamma_2\) is

\[
r = (b^2 - \delta^2)^{-1} \left[ (b^2 - a^2)R + (a - \delta)b^3 \frac{\delta^3}{R^2} \right]. \tag{38}
\]

However, this transformation function is generally not one-to-one. The problem is illustrated in Fig. 7, and comes from the fact that \(dr/dR = 0\) at some value of \(R \in (\delta, b)\).

This cannot occur for the mapping function \(36\). Consequently equation \(36\) is a valid transformation for acoustic cloaking while equation \(38\) is not.

**B. Optimal transformation for spherical cloaks**

We now take Eqs. \(34a\) and \(34b\) as the definition of the global anisotropy measures. Using again the inverse mapping \(X = f(r)r^{-1}X\) it follows that \(\nabla^2 X = [(v^2f')' - 2f(f^2)'X\). The transformation which minimizes \(\gamma_1\) is therefore

\[
f(r) = (b^3 - a^3)^{-1} \left[ (b^3 - a^2) - (a - \delta)b^3 \frac{\delta^3}{R^2} \right]. \tag{39}
\]

The transformation which minimizes \(\gamma_2\) is

\[
r = (b^3 - \delta^3)^{-1} \left[ (b^3 - a^2)R + (a - \delta)b^3 \frac{\delta^3}{R^2} \right]. \tag{40}
\]

but this again has the unphysical nature found for the 2D case. We conclude that minimization of \(\gamma_2\) using a single valued function does not appear to have a single or unique solution.

**C. Numerical examples**

The minimizing value of \(\gamma_1\) may be found by integrating Eq. \(34a\) by parts, and using Eq. \(35a\),

\[
\gamma_{1\text{min}} = \begin{cases} 
\frac{1}{\pi(b^2 - a^2)} (2\pi \int f')^b_{a} & \text{2D}, \\
\frac{1}{4\pi(b^3 - a^3)} (4\pi^2 \int f')^b_{a} & \text{3D}.
\end{cases} \tag{41}
\]

Thus,

\[
\gamma_{1\text{min}} = \begin{cases} 
2(b^2 - a^2)^{-2} [(b^2 - a^2)^2 + (a - \delta)^2 b^2)] & \text{2D}, \\
3(b^3 - a^3)^{-2} [(b^3 - a^2)^2 + (a - \delta)^2 b^3)] & \text{3D}.
\end{cases} \tag{42}
\]

The relative value of the anisotropy parameter \(\gamma_1\) is shown in Fig. 8 for the three mappings of Eq. \(2\). In all cases, the value of \(\gamma_1\) exceeds the minimum \(\gamma_{1\text{min}}\) for the optimal transformations in Eqs. \(36\) and \(39\). The KSVW mapping in 2D has anisotropy.
VI. CONCLUSION AND DISCUSSION

Transformation acoustics, like its close analog transformation optics, possesses a huge freedom in the way that the transformation can be chosen. This paper sheds some light on potential choices. We have shown that it is possible to always fix at least one of the three material parameters relevant to radially symmetric deformations. Starting from the theory of Norris,11 we have derived several forms of the transformation \( f \) which yield specialized distributions of material properties such as constant and power law density, radial stiffness, and tangential stiffness. This was achieved by reinterpreting the governing equations for the material properties as differential equations for the transformations. We derived a functional form of \( f \) that minimizes elastic anisotropy in a certain sense.
