in Quantum Mechanics, Statistics,
Polymer Physics, and Financial Markets

Path Integrals in Quantum Mechanics, Statistics, Polymer Physics, and Financial Markets

Hagen Kleinert

Professor of Physics

Freie Universität Berlin, Germany

ICRANet Pescara, Italy, and Nice, France

To Annemarie and Hagen II

Nature alone knows what she wants.
GOETHE

Preface to the Fifth Edition

The paperback version of the fourth edition of this book was sold out in Fall 2008. This gave me a chance to revise it at many places. In particular, I improved considerably Chapter 20 on financial markets and removed some technical sections of Chapter 5.

Among the many people who spotted printing errors and suggested changes of various text passages are Dr. A. Pelster, Dr. A. Redondo, and especially Dr. Annemarie Kleinert.

Nature alone knows what she wants.
GOETHE

Preface to Fourth Edition

The third edition of this book appeared in 2004 and was reprinted in the same year without improvements. The present fourth edition contains several extensions. Chapter 4 includes now semiclassical expansions of higher order. Chapter 8 offers an additional path integral formulation of spinning particles whose action contains a vector field and a Wess-Zumino term. From this, the Landau-Lifshitz equation for spin precession is derived which governs the behavior of quantum spin liquids. The path integral demonstrates that fermions can be described by Bose fields—the basis of Skyrmion theories. A further new section introduces the Berry phase, a useful tool to explain many interesting physical phenomena. Chapter 10 gives more details on magnetic monopoles and multivalued fields. Another feature is new in this edition: sections of a more technical nature are printed in smaller font size. They can well be omitted in a first reading of the book.

Among the many people who spotted printing errors and helped me improve various text passages are Dr. A. Chervyakov, Dr. A. Pelster, Dr. F. Nogueira, Dr. M. Weyrauch, Dr. H. Baur, Dr. T. Iguchi, V. Bezerra, D. Jahn, S. Overesch, and especially Dr. Annemarie Kleinert.

Preface to Third Edition

This third edition of the book improves and extends considerably the second edition of 1995:

- Chapter 2 now contains a path integral representation of the scattering amplitude and new methods of calculating functional determinants for time-dependent second-order differential operators. Most importantly, it introduces the quantum field-theoretic definition of path integrals, based on perturbation expansions around the trivial harmonic theory.
- Chapter 3 presents more exactly solvable path integrals than in the previous editions. It also extends the Bender-Wu recursion relations for calculating perturbation expansions to more general types of potentials.
- Chapter 4 discusses now in detail the quasiclassical approximation to the scattering amplitude and Thomas-Fermi approximation to atoms.
- Chapter 5 proves the convergence of variational perturbation theory. It also discusses atoms in strong magnetic fields and the polaron problem.
- Chapter 6 shows how to obtain the spectrum of systems with infinitely high walls from perturbation expansions.
- Chapter 7 offers a many-path treatment of Bose-Einstein condensation and degenerate Fermi gases.
- Chapter 10 develops the quantum theory of a particle in curved space, treated before only in the time-sliced formalism, to perturbatively defined path integrals. Their reparametrization invariance imposes severe constraints upon integrals over products of distributions. We derive unique rules for evaluating these integrals, thus extending the linear space of distributions to a semigroup.
- Chapter 15 offers a closed expression for the end-to-end distribution of stiff polymers valid for all persistence lengths.
- Chapter 18 derives the operator Langevin equation and the Fokker-Planck equation from the forward-backward path integral. The derivation in the literature was incomplete, and the gap was closed only recently by an elegant calculation of the Jacobian functional determinant of a second-order differential operator with dissipation.

- Chapter 20 is completely new. It introduces the reader into the applications of path integrals to the fascinating new field of econophysics.

For a few years, the third edition has been freely available on the internet, and several readers have sent useful comments, for instance E. Babaev, H. Baur, B. Budnyj, Chen Li-ming, A.A. Drăgulescu, K. Glaum, I. Grigorenko, T.S. Hatamian, P. Hollister, P. Jizba, B. Kastening, M. Krämer, W.-F. Lu, S. Mukhin, A. Pelster, M.B. Pinto, C. Schubert, S. Schmidt, R. Scalettar, C. Tangui, and M. van Vugt. Reported errors are corrected in the internet edition.

When writing the new part of Chapter 2 on the path integral representation of the scattering amplitude I profited from discussions with R. Rosenfelder. In the new parts of Chapter 5 on polarons, many useful comments came from J.T. Devreese, F.M. Peeters, and F. Brosens. In the new Chapter 20, I profited from discussions with F. Nogueira, A.A. Drăgulescu, E. Eberlein, J. Kallsen, M. Schweizer, P. Bank, M. Tenney, and E.C. Chang.

As in all my books, many printing errors were detected by my secretary S. Endrias and many improvements are due to my wife Annemarie without whose permanent encouragement this book would never have been finished.

H. Kleinert

Berlin, August 2003

Preface to Second Edition

Since this book first appeared three years ago, a number of important developments have taken place calling for various extensions to the text.

Chapter 4 now contains a discussion of the features of the semiclassical quantization which are relevant for multidimensional chaotic systems.

Chapter 3 derives perturbation expansions in terms of Feynman graphs, whose use is customary in quantum field theory. Correspondence is established with Rayleigh-Schrödinger perturbation theory. Graphical expansions are used in Chapter 5 to extend the Feynman-Kleinert variational approach into a systematic *variational perturbation theory*. Analytically inaccessible path integrals can now be evaluated with arbitrary accuracy. In contrast to ordinary perturbation expansions which always diverge, the new expansions are convergent for all coupling strengths, including the strong-coupling limit.

Chapter 10 contains now a new action principle which is necessary to derive the correct classical equations of motion in spaces with curvature and a certain class of torsion (gradient torsion).

Chapter 19 is new. It deals with relativistic path integrals, which were previously discussed only briefly in two sections at the end of Chapter 15. As an application, the path integral of the relativistic hydrogen atom is solved.

Chapter 16 is extended by a theory of particles with fractional statistics (*anyons*), from which I develop a theory of polymer entanglement. For this I introduce non-abelian Chern-Simons fields and show their relationship with various knot polynomials (Jones, HOMFLY). The successful explanation of the fractional quantum Hall effect by anyon theory is discussed — also the failure to explain high-temperature superconductivity via a Chern-Simons interaction.

Chapter 17 offers a novel variational approach to tunneling amplitudes. It extends the semiclassical range of validity from high to low barriers. As an application, I increase the range of validity of the currently used large-order perturbation theory far into the regime of low orders. This suggests a possibility of greatly improving existing resummation procedures for divergent perturbation series of quantum field theories.

The Index now also contains the names of authors cited in the text. This may help the reader searching for topics associated with these names. Due to their great number, it was impossible to cite all the authors who have made important contributions. I apologize to all those who vainly search for their names.

In writing the new sections in Chapters 4 and 16, discussions with Dr. D. Wintgen and, in particular, Dr. A. Schakel have been extremely useful. I also thank Professors G. Gerlich, P. Hänggi, H. Grabert, M. Roncadelli, as well as Dr. A. Pelster, and Mr. R. Karrlein for many relevant comments. Printing errors were corrected by my secretary Ms. S. Endrias and by my editor Ms. Lim Feng Nee of World Scientific.

Many improvements are due to my wife Annemarie.

H. Kleinert

Berlin, December 1994

Preface to First Edition

These are extended lecture notes of a course on path integrals which I delivered at the Freie Universität Berlin during winter 1989/1990. My interest in this subject dates back to 1972 when the late R. P. Feynman drew my attention to the unsolved path integral of the hydrogen atom. I was then spending my sabbatical year at Caltech, where Feynman told me during a discussion how embarrassed he was, not being able to solve the path integral of this most fundamental quantum system. In fact, this had made him quit teaching this subject in his course on quantum mechanics as he had initially done.¹ Feynman challenged me: “Kleinert, you figured out all that group-theoretic stuff of the hydrogen atom, why don’t you solve the path integral!” He was referring to my 1967 Ph.D. thesis² where I had demonstrated that all dynamical questions on the hydrogen atom could be answered using only operations within a *dynamical group* $O(4, 2)$. Indeed, in that work, the four-dimensional oscillator played a crucial role and the missing steps to the solution of the path integral were later found to be very few. After returning to Berlin, I forgot about the problem since I was busy applying path integrals in another context, developing a field-theoretic passage from quark theories to a collective field theory of hadrons.³ Later, I carried these techniques over into condensed matter (superconductors, superfluid ^3He) and nuclear physics. Path integrals have made it possible to build a unified field theory of collective phenomena in quite different physical systems.⁴

The hydrogen problem came up again in 1978 as I was teaching a course on quantum mechanics. To explain the concept of quantum fluctuations, I gave an introduction to path integrals. At the same time, a postdoc from Turkey, I. H. Duru, joined my group as a Humboldt fellow. Since he was familiar with quantum mechanics, I suggested that we should try solving the path integral of the hydrogen atom. He quickly acquired the basic techniques, and soon we found the most important ingredient to the solution: The transformation of time in the path integral to a new path-dependent pseudotime, combined with a transformation of the coordinates to

¹Quoting from the preface of the textbook by R.P. Feynman and A.R. Hibbs, *Quantum Mechanics and Path Integrals*, McGraw-Hill, New York, 1965: “Over the succeeding years, ... Dr. Feynman’s approach to teaching the subject of quantum mechanics evolved somewhat away from the initial path integral approach.”

³See my 1976 Erice lectures, *Hadronization of Quark Theories*, published in *Understanding the Fundamental Constituents of Matter*, Plenum press, New York, 1978, p. 289, ed. by A. Zichichi.

⁴H. Kleinert, *Phys. Lett. B* *69*, 9 (1977); *Fortschr. Phys.* *26*, 565 (1978); *30*, 187, 351 (1982).

“square root coordinates” (to be explained in Chapters 13 and 14).⁵ These transformations led to the correct result, however, only due to good fortune. In fact, our procedure was immediately criticized for its sloppy treatment of the time slicing.⁶ A proper treatment could, in principle, have rendered unwanted extra terms which our treatment would have missed. Other authors went through the detailed time-slicing procedure,⁷ but the correct result emerged only by transforming the measure of path integration inconsistently. When I calculated the extra terms according to the standard rules I found them to be zero only in two space dimensions.⁸ The same treatment in three dimensions gave nonzero “corrections” which spoiled the beautiful result, leaving me puzzled.

Only recently I happened to locate the place where the three-dimensional treatment went wrong. I had just finished a book on the use of gauge fields in condensed matter physics.⁹ The second volume deals with ensembles of defects which are defined and classified by means of operational cutting and pasting procedures on an ideal crystal. Mathematically, these procedures correspond to nonholonomic mappings. Geometrically, they lead from a flat space to a space with curvature and torsion. While proofreading that book, I realized that the transformation by which the path integral of the hydrogen atom is solved also produces a certain type of torsion (gradient torsion). Moreover, this happens only in three dimensions. In two dimensions, where the time-sliced path integral had been solved without problems, torsion is absent. Thus I realized that the transformation of the time-sliced measure had a hitherto unknown sensitivity to torsion.

It was therefore essential to find a correct path integral for a particle in a space with curvature and gradient torsion. This was a nontrivial task since the literature was ambiguous already for a purely curved space, offering several prescriptions to choose from. The corresponding equivalent Schrödinger equations differ by multiples of the curvature scalar.¹⁰ The ambiguities are path integral analogs of the so-called *operator-ordering problem* in quantum mechanics. When trying to apply the existing prescriptions to spaces with torsion, I always ran into a disaster, some even yielding noncovariant answers. So, something had to be wrong with all of them. Guided by the idea that in spaces with constant curvature the path integral should produce the same result as an operator quantum mechanics based on a quantization of angular momenta, I was eventually able to find a consistent *quantum equivalence principle*

for path integrals in spaces with curvature and gradient torsion,¹¹ thus offering also a unique solution to the operator-ordering problem. This was the key to the leftover problem in the Coulomb path integral in three dimensions — the proof of the absence of the extra time slicing contributions presented in Chapter 13.

Chapter 14 solves a variety of one-dimensional systems by the new techniques.

Special emphasis is given in Chapter 8 to instability (*path collapse*) problems in the Euclidean version of Feynman's time-sliced path integral. These arise for actions containing bottomless potentials. A general stabilization procedure is developed in Chapter 12. It must be applied whenever centrifugal barriers, angular barriers, or Coulomb potentials are present.¹²

Another project suggested to me by Feynman, the improvement of a variational approach to path integrals explained in his book on statistical mechanics¹³, found a faster solution. We started work during my sabbatical stay at the University of California at Santa Barbara in 1982. After a few meetings and discussions, the problem was solved and the preprint drafted. Unfortunately, Feynman's illness prevented him from reading the final proof of the paper. He was able to do this only three years later when I came to the University of California at San Diego for another sabbatical leave. Only then could the paper be submitted.¹⁴

Due to recent interest in lattice theories, I have found it useful to exhibit the solution of several path integrals for a finite number of time slices, without going immediately to the continuum limit. This should help identify typical lattice effects seen in the Monte Carlo simulation data of various systems.

The path integral description of polymers is introduced in Chapter 15 where stiffness as well as the famous excluded-volume problem are discussed. Parallels are drawn to path integrals of relativistic particle orbits. This chapter is a preparation for ongoing research in the theory of fluctuating surfaces with extrinsic curvature stiffness, and their application to world sheets of strings in particle physics.¹⁵ I have also introduced the field-theoretic description of a polymer to account for its increasing relevance to the understanding of various phase transitions driven by fluctuating line-like excitations (vortex lines in superfluids and superconductors, defect lines in crystals and liquid crystals).¹⁶ Special attention has been devoted in Chapter 16 to simple topological questions of polymers and particle orbits, the latter arising by the presence of magnetic flux tubes (Aharonov-Bohm effect). Their relationship to Bose and Fermi statistics of particles is pointed out and the recently popular topic of fractional statistics is introduced. A survey of entanglement phenomena of single orbits and pairs of them (ribbons) is given and their application to biophysics is indicated.

Finally, Chapter 18 contains a brief introduction to the path integral approach of nonequilibrium quantum-statistical mechanics, deriving from it the standard Langevin and Fokker-Planck equations.

I want to thank several students in my class, my graduate students, and my post-docs for many useful discussions. In particular, T. Eris, F. Langhammer, B. Meller, I. Mustapic, T. Sauer, L. Semig, J. Zaun, and Drs. G. Germán, C. Holm, D. Johnston, and P. Kornilovitch have all contributed with constructive criticism. Dr. U. Eckern from Karlsruhe University clarified some points in the path integral derivation of the Fokker-Planck equation in Chapter 18. Useful comments are due to Dr. P.A. Horvathy, Dr. J. Whittenton, and to my colleague Prof. W. Theis. Their careful reading uncovered many shortcomings in the first draft of the manuscript. Special thanks go to Dr. W. Janke with whom I had a fertile collaboration over the years and many discussions on various aspects of path integration.

Thanks go also to my secretary S. Endrias for her help in preparing the manuscript in \LaTeX , thus making it readable at an early stage, and to U. Grimm for drawing the figures.

Finally, and most importantly, I am grateful to my wife Dr. Annemarie Kleinert for her inexhaustible patience and constant encouragement.

Fundamentals

Path integrals deal with fluctuating line-like structures. These appear in nature in a variety of ways, for instance, as particle orbits in spacetime continua, as polymers in solutions, as vortex lines in superfluids, as defect lines in crystals and liquid crystals. Their fluctuations can be of quantum-mechanical, thermodynamic, or statistical origin. Path integrals are an ideal tool to describe these fluctuating line-like structures, thereby leading to a unified understanding of many quite different physical phenomena. In developing the formalism we shall repeatedly invoke well-known concepts of classical mechanics, quantum mechanics, and statistical mechanics, to be summarized in this chapter. In Section 1.13, we emphasize some important problems of operator quantum mechanics in spaces with curvature and torsion. These problems will be solved in Chapters 10 and 8 by means of path integrals.¹

1.1 Classical Mechanics

The orbits of a classical-mechanical system are described by a set of time-dependent generalized coordinates $q_1(t), \dots, q_N(t)$. A Lagrangian

$$L(q_i, \dot{q}_i, t) \tag{1.1}$$

depending on q_1, \dots, q_N and the associated velocities $\dot{q}_1, \dots, \dot{q}_N$ governs the dynamics of the system. The dots denote the time derivative d/dt . The Lagrangian is at most a quadratic function of \dot{q}_i . The time integral

$$\mathcal{A}[q_i] = \int_{t_a}^{t_b} dt L(q_i(t), \dot{q}_i(t), t) \tag{1.2}$$

of the Lagrangian along an arbitrary path $q_i(t)$ is called the *action* of this path. The path being actually chosen by the system as a function of time is called the *classical path* or the *classical orbit* $q_i^{\text{cl}}(t)$. It has the property of extremizing the action in comparison with all neighboring paths

$$q_i(t) = q_i^{\text{cl}}(t) + \delta q_i(t) \tag{1.3}$$

¹Readers familiar with the foundations may start directly with Section 1.13.

having the same endpoints $q(t_b)$, $q(t_a)$. To express this property formally, one introduces the *variation* of the action as the linear term in the Taylor expansion of $\mathcal{A}[q_i]$ in powers of $\delta q_i(t)$:

$$\delta\mathcal{A}[q_i] \equiv \{\mathcal{A}[q_i + \delta q_i] - \mathcal{A}[q_i]\}_{\text{lin term in } \delta q_i} \quad . \quad (1.4)$$

The extremal principle for the classical path is then

$$\delta\mathcal{A}[q_i] \Big|_{q_i(t)=q_i^{\text{cl}}(t)} = 0 \quad (1.5)$$

for all variations of the path around the classical path, $\delta q_i(t) \equiv q_i(t) - q_i^{\text{cl}}(t)$, which vanish at the endpoints, i.e., which satisfy

$$\delta q_i(t_a) = \delta q_i(t_b) = 0. \quad (1.6)$$

Since the action is a time integral of a Lagrangian, the extremality property can be phrased in terms of differential equations. Let us calculate the variation of $\mathcal{A}[q_i]$ explicitly:

$$\begin{aligned} \delta\mathcal{A}[q_i] &= \{\mathcal{A}[q_i + \delta q_i] - \mathcal{A}[q_i]\}_{\text{lin}} \\ &= \int_{t_a}^{t_b} dt \{L(q_i(t) + \delta q_i(t), \dot{q}_i(t) + \delta \dot{q}_i(t), t) - L(q_i(t), \dot{q}_i(t), t)\}_{\text{lin}} \\ &= \int_{t_a}^{t_b} dt \left\{ \frac{\partial L}{\partial q_i} \delta q_i(t) + \frac{\partial L}{\partial \dot{q}_i} \delta \dot{q}_i(t) \right\} \\ &= \int_{t_a}^{t_b} dt \left\{ \frac{\partial L}{\partial q_i} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_i} \right\} \delta q_i(t) + \frac{\partial L}{\partial \dot{q}_i} \delta q_i(t) \Big|_{t_a}^{t_b}. \end{aligned} \quad (1.7)$$

The last expression arises from a partial integration of the $\delta \dot{q}_i$ term. Here, as in the entire text, repeated indices are understood to be summed (*Einstein's summation convention*). The endpoint terms (*surface or boundary terms*) with the time t equal to t_a and t_b may be dropped, due to (1.6). Thus we find for the classical orbit $q_i^{\text{cl}}(t)$ the *Euler-Lagrange equations*:

$$\frac{d}{dt} \frac{\partial L}{\partial \dot{q}_i} = \frac{\partial L}{\partial q_i}. \quad (1.8)$$

There is an alternative formulation of classical dynamics which is based on a Legendre-transformed function of the Lagrangian called the *Hamiltonian*

$$H \equiv \frac{\partial L}{\partial \dot{q}_i} \dot{q}_i - L(q_i, \dot{q}_i, t). \quad (1.9)$$

Its value at any time is equal to the energy of the system. According to the general theory of Legendre transformations [1], the natural variables which H depends on are no longer q_i and \dot{q}_i , but q_i and the generalized momenta p_i , the latter being defined by the N equations

$$p_i \equiv \frac{\partial}{\partial \dot{q}_i} L(q_i, \dot{q}_i, t). \quad (1.10)$$

In order to express the Hamiltonian $H(p_i, q_i, t)$ in terms of its proper variables p_i, q_i , the equations (1.10) have to be solved for \dot{q}_i by a velocity function

$$\dot{q}_i = v_i(p_i, q_i, t). \quad (1.11)$$

This is possible provided the *Hessian metric*

$$h_{ij}(q_i, \dot{q}_i, t) \equiv \frac{\partial^2}{\partial \dot{q}_i \partial \dot{q}_j} L(q_i, \dot{q}_i, t) \quad (1.12)$$

is nonsingular. The result is inserted into (1.9), leading to the Hamiltonian as a function of p_i and q_i :

$$H(p_i, q_i, t) = p_i v_i(p_i, q_i, t) - L(q_i, v_i(p_i, q_i, t), t). \quad (1.13)$$

In terms of this Hamiltonian, the action is the following functional of $p_i(t)$ and $q_i(t)$:

$$\mathcal{A}[p_i, q_i] = \int_{t_a}^{t_b} dt [p_i(t) \dot{q}_i(t) - H(p_i(t), q_i(t), t)]. \quad (1.14)$$

This is the so-called *canonical form* of the action. The classical orbits are now specified by $p_i^{\text{cl}}(t), q_i^{\text{cl}}(t)$. They extremize the action in comparison with all neighboring orbits in which the coordinates $q_i(t)$ are varied at fixed endpoints [see (1.3), (1.6)] whereas the momenta $p_i(t)$ are varied without restriction:

$$\begin{aligned} q_i(t) &= q_i^{\text{cl}}(t) + \delta q_i(t), & \delta q_i(t_a) = \delta q_i(t_b) = 0, \\ p_i(t) &= p_i^{\text{cl}}(t) + \delta p_i(t). \end{aligned} \quad (1.15)$$

In general, the variation is

$$\begin{aligned} \delta \mathcal{A}[p_i, q_i] &= \int_{t_a}^{t_b} dt \left[\delta p_i(t) \dot{q}_i(t) + p_i(t) \delta \dot{q}_i(t) - \frac{\partial H}{\partial p_i} \delta p_i - \frac{\partial H}{\partial q_i} \delta q_i \right] \\ &= \int_{t_a}^{t_b} dt \left\{ \left[\dot{q}_i(t) - \frac{\partial H}{\partial p_i} \right] \delta p_i - \left[\dot{p}_i(t) + \frac{\partial H}{\partial q_i} \right] \delta q_i \right\} \\ &\quad + p_i(t) \delta q_i(t) \Big|_{t_a}^{t_b}. \end{aligned} \quad (1.16)$$

Since this variation has to vanish for the classical orbits, we find that $p_i^{\text{cl}}(t), q_i^{\text{cl}}(t)$ must be solutions of the *Hamilton equations* of motion

$$\begin{aligned} \dot{p}_i &= -\frac{\partial H}{\partial q_i}, \\ \dot{q}_i &= \frac{\partial H}{\partial p_i}. \end{aligned} \quad (1.17)$$

These agree with the Euler-Lagrange equations (1.8) via (1.9) and (1.10), as can easily be verified. The $2N$ -dimensional space of all p_i and q_i is called the *phase space*.

An arbitrary function $O(p_i(t), q_i(t), t)$ changes along an arbitrary path as follows:

$$\frac{d}{dt}O(p_i(t), q_i(t), t) = \frac{\partial O}{\partial p_i}\dot{p}_i + \frac{\partial O}{\partial q_i}\dot{q}_i + \frac{\partial O}{\partial t}. \quad (1.18)$$

If the path coincides with a classical orbit, we may insert (1.17) and find

$$\begin{aligned} \frac{dO}{dt} &= \frac{\partial H}{\partial p_i} \frac{\partial O}{\partial q_i} - \frac{\partial O}{\partial p_i} \frac{\partial H}{\partial q_i} + \frac{\partial O}{\partial t} \\ &\equiv \{H, O\} + \frac{\partial O}{\partial t}. \end{aligned} \quad (1.19)$$

Here we have introduced the symbol $\{\dots, \dots\}$ called *Poisson brackets*:

$$\{A, B\} \equiv \frac{\partial A}{\partial p_i} \frac{\partial B}{\partial q_i} - \frac{\partial B}{\partial p_i} \frac{\partial A}{\partial q_i}, \quad (1.20)$$

again with the Einstein summation convention for the repeated index i . The Poisson brackets have the obvious properties

$$\{A, B\} = -\{B, A\} \quad \text{antisymmetry,} \quad (1.21)$$

$$\{A, \{B, C\}\} + \{B, \{C, A\}\} + \{C, \{A, B\}\} = 0 \quad \text{Jacobi identity.} \quad (1.22)$$

If two quantities have vanishing Poisson brackets, they are said to *commute*.

The original Hamilton equations are a special case of (1.19):

$$\begin{aligned} \frac{d}{dt}p_i &= \{H, p_i\} = \frac{\partial H}{\partial p_j} \frac{\partial p_i}{\partial q_j} - \frac{\partial p_i}{\partial p_j} \frac{\partial H}{\partial q_j} = -\frac{\partial H}{\partial q_i}, \\ \frac{d}{dt}q_i &= \{H, q_i\} = \frac{\partial H}{\partial p_j} \frac{\partial q_i}{\partial q_j} - \frac{\partial q_i}{\partial p_j} \frac{\partial H}{\partial q_j} = \frac{\partial H}{\partial p_i}. \end{aligned} \quad (1.23)$$

By definition, the phase space variables p_i, q_i satisfy the Poisson brackets

$$\begin{aligned} \{p_i, q_j\} &= \delta_{ij}, \\ \{p_i, p_j\} &= 0, \\ \{q_i, q_j\} &= 0. \end{aligned} \quad (1.24)$$

A function $O(p_i, q_i)$ which has no *explicit* dependence on time and which, moreover, commutes with H (i.e., $\{O, H\} = 0$), is a *constant of motion* along the classical path, due to (1.19). In particular, H itself is often time-independent, i.e., of the form

$$H = H(p_i, q_i). \quad (1.25)$$

Then, since H commutes with itself, the energy is a constant of motion.

The Lagrangian formalism has the virtue of being independent of the particular choice of the coordinates q_i . Let Q_i be any other set of coordinates describing the system which is connected with q_i by what is called a *local*² or *point transformation*

$$q_i = f_i(Q_j, t). \quad (1.26)$$

Certainly, to be of use, this relation must be invertible, at least in some neighborhood of the classical path,

$$Q_i = f_i^{-1}(q_j, t). \quad (1.27)$$

Otherwise Q_i and q_i could not both parametrize the same system. Therefore, f_i must have a nonvanishing Jacobi determinant:

$$\det \left(\frac{\partial f_i}{\partial Q_j} \right) \neq 0. \quad (1.28)$$

In terms of Q_i , the initial Lagrangian takes the form

$$L' (Q_j, \dot{Q}_j, t) \equiv L (f_i(Q_j, t), \dot{f}_i(Q_j, t), t) \quad (1.29)$$

and the action reads

$$\begin{aligned} \mathcal{A} &= \int_{t_a}^{t_b} dt L' (Q_j(t), \dot{Q}_j(t), t) \\ &= \int_{t_a}^{t_b} dt L (f_i(Q_j(t), t), \dot{f}_i(Q_j(t), t), t). \end{aligned} \quad (1.30)$$

By performing variations $\delta Q_j(t)$, $\delta \dot{Q}_j(t)$ in the first expression while keeping $\delta Q_j(t_a) = \delta Q_j(t_b) = 0$, we find the equations of motion

$$\frac{d}{dt} \frac{\partial L'}{\partial \dot{Q}_j} - \frac{\partial L'}{\partial Q_j} = 0. \quad (1.31)$$

The variation of the lower expression, on the other hand, gives

$$\begin{aligned} \delta \mathcal{A} &= \int_{t_a}^{t_b} dt \left(\frac{\partial L}{\partial q_i} \delta f_i + \frac{\partial L}{\partial \dot{q}_i} \delta \dot{f}_i \right) \\ &= \int_{t_a}^{t_b} dt \left(\frac{\partial L}{\partial q_i} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_i} \right) \delta f_i + \frac{\partial L}{\partial \dot{q}_i} \delta f_i \Big|_{t_a}^{t_b}. \end{aligned} \quad (1.32)$$

If δq_i is arbitrary, then so is δf_i . Moreover, with $\delta q_i(t_a) = \delta q_i(t_b) = 0$, also δf_i vanishes at the endpoints. Hence the extremum of the action is determined equally well by the Euler-Lagrange equations for $Q_j(t)$ [as it was by those for $q_i(t)$].

²The word *local* means here *at a specific time*. This terminology is of common use in field theory where *local* means, more generally, *at a specific spacetime point*.

Note that the locality property is quite restrictive for the transformation of the generalized velocities $\dot{q}_i(t)$. They will necessarily be linear in \dot{Q}_j :

$$\dot{q}_i = \dot{f}_i(Q_j, t) = \frac{\partial f_i}{\partial Q_j} \dot{Q}_j + \frac{\partial f_i}{\partial t}. \quad (1.33)$$

In phase space, there exists also the possibility of performing local changes of the canonical coordinates p_i, q_i to new ones P_j, Q_j . Let them be related by

$$\begin{aligned} p_i &= p_i(P_j, Q_j, t), \\ q_i &= q_i(P_j, Q_j, t), \end{aligned} \quad (1.34)$$

with the inverse relations

$$\begin{aligned} P_j &= P_j(p_i, q_i, t), \\ Q_j &= Q_j(p_i, q_i, t). \end{aligned} \quad (1.35)$$

However, while the Euler-Lagrange equations maintain their form under *any* local change of coordinates, the Hamilton equations do not hold, in general, for any transformed coordinates $P_j(t), Q_j(t)$. The local transformations $p_i(t), q_i(t) \rightarrow P_j(t), Q_j(t)$ for which they hold, are referred to as *canonical*. They are characterized by the form invariance of the action, up to an arbitrary surface term,

$$\begin{aligned} \int_{t_a}^{t_b} dt [p_i \dot{q}_i - H(p_i, q_i, t)] &= \int_{t_a}^{t_b} dt [P_j \dot{Q}_j - H'(P_j, Q_j, t)] \\ &\quad + F(P_j, Q_j, t) \Big|_{t_a}^{t_b}, \end{aligned} \quad (1.36)$$

where $H'(P_j, Q_j, t)$ is some new Hamiltonian. Its relation with $H(p_i, q_i, t)$ must be chosen in such a way that the equality of the action holds for *any* path $p_i(t), q_i(t)$ connecting the same endpoints (at least any in some neighborhood of the classical orbits). If such an invariance exists then a variation of this action yields for $P_j(t)$ and $Q_j(t)$ the Hamilton equations of motion governed by H' :

$$\begin{aligned} \dot{P}_i &= -\frac{\partial H'}{\partial Q_i}, \\ \dot{Q}_i &= \frac{\partial H'}{\partial P_i}. \end{aligned} \quad (1.37)$$

The invariance (1.36) can be expressed differently by rewriting the integral on the left-hand side in terms of the new variables $P_j(t), Q_j(t)$,

$$\int_{t_a}^{t_b} dt \left\{ p_i \left(\frac{\partial q_i}{\partial P_j} \dot{P}_j + \frac{\partial q_i}{\partial Q_j} \dot{Q}_j + \frac{\partial q_i}{\partial t} \right) - H(p_i(P_j, Q_j, t), q_i(P_j, Q_j, t), t) \right\}, \quad (1.38)$$

and subtracting it from the right-hand side, leading to

$$\begin{aligned} \int_{t_a}^{t_b} \left\{ \left(P_j - p_i \frac{\partial q_i}{\partial Q_j} \right) dQ_j - p_i \frac{\partial q_i}{\partial P_j} dP_j \right. \\ \left. - \left(H' + p_i \frac{\partial q_i}{\partial t} - H \right) dt \right\} &= -F(P_j, Q_j, t) \Big|_{t_a}^{t_b}. \end{aligned} \quad (1.39)$$

The integral is now a line integral along a curve in the $(2N + 1)$ -dimensional space, consisting of the $2N$ -dimensional phase space variables p_i, q_i and of the time t . The right-hand side depends only on the endpoints. Thus we conclude that the integrand on the left-hand side must be a total differential. As such it has to satisfy the standard Schwarz integrability conditions [2], according to which all second derivatives have to be independent of the sequence of differentiation. Explicitly, these conditions are

$$\begin{aligned}\frac{\partial p_i}{\partial P_k} \frac{\partial q_i}{\partial Q_l} - \frac{\partial q_i}{\partial P_k} \frac{\partial p_i}{\partial Q_l} &= \delta_{kl}, \\ \frac{\partial p_i}{\partial P_k} \frac{\partial q_i}{\partial P_l} - \frac{\partial q_i}{\partial P_k} \frac{\partial p_i}{\partial P_l} &= 0, \\ \frac{\partial p_i}{\partial Q_k} \frac{\partial q_i}{\partial Q_l} - \frac{\partial q_i}{\partial Q_k} \frac{\partial p_i}{\partial Q_l} &= 0,\end{aligned}\tag{1.40}$$

and

$$\begin{aligned}\frac{\partial p_i}{\partial t} \frac{\partial q_i}{\partial P_l} - \frac{\partial q_i}{\partial t} \frac{\partial p_i}{\partial P_l} &= \frac{\partial(H' - H)}{\partial P_l}, \\ \frac{\partial p_i}{\partial t} \frac{\partial q_i}{\partial Q_l} - \frac{\partial q_i}{\partial t} \frac{\partial p_i}{\partial Q_l} &= \frac{\partial(H' - H)}{\partial Q_l}.\end{aligned}\tag{1.41}$$

The first three equations define the so-called *Lagrange brackets* in terms of which they are written as

$$\begin{aligned}(P_k, Q_l) &= \delta_{kl}, \\ (P_k, P_l) &= 0, \\ (Q_k, Q_l) &= 0.\end{aligned}\tag{1.42}$$

Time-dependent coordinate transformations satisfying these equations are called *symplectic*. After a little algebra involving the matrix of derivatives

$$J = \begin{pmatrix} \partial P_i / \partial p_j & \partial P_i / \partial q_j \\ \partial Q_i / \partial p_j & \partial Q_i / \partial q_j \end{pmatrix},\tag{1.43}$$

its inverse

$$J^{-1} = \begin{pmatrix} \partial p_i / \partial P_j & \partial p_i / \partial Q_j \\ \partial q_i / \partial P_j & \partial q_i / \partial Q_j \end{pmatrix},\tag{1.44}$$

and the symplectic unit matrix

$$E = \begin{pmatrix} 0 & \delta_{ij} \\ -\delta_{ij} & 0 \end{pmatrix},\tag{1.45}$$

we find that the Lagrange brackets (1.42) are equivalent to the Poisson brackets

$$\begin{aligned}\{P_k, Q_l\} &= \delta_{kl}, \\ \{P_k, P_l\} &= 0, \\ \{Q_k, Q_l\} &= 0.\end{aligned}\tag{1.46}$$

This follows from the fact that the $2N \times 2N$ matrix formed from the Lagrange brackets

$$\mathcal{L} \equiv \begin{pmatrix} -(Q_i, P_j) & -(Q_i, Q_j) \\ (P_i, P_j) & (P_i, Q_j) \end{pmatrix} \quad (1.47)$$

can be written as $(E^{-1}J^{-1}E)^T J^{-1}$, while an analogous matrix formed from the Poisson brackets

$$\mathcal{P} \equiv \begin{pmatrix} \{P_i, Q_j\} & -\{P_i, P_j\} \\ \{Q_i, Q_j\} & -\{Q_i, P_j\} \end{pmatrix} \quad (1.48)$$

is equal to $J(E^{-1}JE)^T$. Hence $\mathcal{L} = \mathcal{P}^{-1}$, so that (1.42) and (1.46) are equivalent to each other. Note that the Lagrange brackets (1.42) [and thus the Poisson brackets (1.46)] ensure $p_i \dot{q}_i - P_j \dot{Q}_j$ to be a total differential of some function of P_j and Q_j in the $2N$ -dimensional phase space:

$$p_i \dot{q}_i - P_j \dot{Q}_j = \frac{d}{dt} G(P_j, Q_j, t). \quad (1.49)$$

The Poisson brackets (1.46) for P_i, Q_i have the same form as those in Eqs. (1.24) for the original phase space variables p_i, q_i .

The other two equations (1.41) relate the new Hamiltonian to the old one. They can always be used to construct $H'(P_j, Q_j, t)$ from $H(p_i, q_i, t)$. The Lagrange brackets (1.42) or Poisson brackets (1.46) are therefore both necessary and sufficient for the transformation $p_i, q_i \rightarrow P_j, Q_j$ to be canonical.

A canonical transformation preserves the volume in phase space. This follows from the fact that the matrix product $J(E^{-1}JE)^T$ is equal to the $2N \times 2N$ unit matrix (1.48). Hence $\det(J) = \pm 1$ and

$$\prod_i \int [dp_i dq_i] = \prod_j \int [dP_j dQ_j]. \quad (1.50)$$

It is obvious that the process of canonical transformations is reflexive. It may be viewed just as well from the opposite side, with the roles of p_i, q_i and P_j, Q_j exchanged [we could just as well have considered the integrand (1.39) as a complete differential in P_j, Q_j, t space].

Once a system is described in terms of new canonical coordinates P_j, Q_j , we introduce the new Poisson brackets

$$\{A, B\}' \equiv \frac{\partial A}{\partial P_j} \frac{\partial B}{\partial Q_j} - \frac{\partial B}{\partial P_j} \frac{\partial A}{\partial Q_j}, \quad (1.51)$$

and the equation of motion for an arbitrary observable quantity $O(P_j(t), Q_j(t), t)$ becomes with (1.37)

$$\frac{dO}{dt} = \{H', O\}' + \frac{\partial O}{\partial t}, \quad (1.52)$$

by complete analogy with (1.19). The new Poisson brackets automatically guarantee the canonical commutation rules

$$\begin{aligned}\{P_i, Q_j\}' &= \delta_{ij}, \\ \{P_i, P_j\}' &= 0, \\ \{Q_i, Q_j\}' &= 0.\end{aligned}\tag{1.53}$$

A standard class of canonical transformations can be constructed by introducing a *generating function* F satisfying a relation of the type (1.36), but depending explicitly on half an old and half a new set of canonical coordinates, for instance

$$F = F(q_i, Q_j, t).\tag{1.54}$$

One now considers the equation

$$\int_{t_a}^{t_b} dt [p_i \dot{q}_i - H(p_i, q_i, t)] = \int_{t_a}^{t_b} dt \left[P_j \dot{Q}_j - H'(P_j, Q_j, t) + \frac{d}{dt} F(q_i, Q_j, t) \right],\tag{1.55}$$

replaces $P_j \dot{Q}_j$ by $-\dot{P}_j Q_j + \frac{d}{dt} P_j Q_j$, defines

$$F(q_i, P_j, t) \equiv F(q_i, Q_j, t) + P_j Q_j,$$

and works out the derivatives. This yields

$$\begin{aligned}& \int_{t_a}^{t_b} dt \left\{ p_i \dot{q}_i + \dot{P}_j Q_j - [H(p_i, q_i, t) - H'(P_j, Q_j, t)] \right\} \\ &= \int_{t_a}^{t_b} dt \left\{ \frac{\partial F}{\partial q_i}(q_i, P_j, t) \dot{q}_i + \frac{\partial F}{\partial P_j}(q_i, P_j, t) \dot{P}_j + \frac{\partial F}{\partial t}(q_i, P_j, t) \right\}.\end{aligned}\tag{1.56}$$

A comparison of the two sides yields the equations for the canonical transformation

$$\begin{aligned}p_i &= \frac{\partial}{\partial q_i} F(q_i, P_j, t), \\ Q_j &= \frac{\partial}{\partial P_j} F(q_i, P_j, t).\end{aligned}\tag{1.57}$$

The second equation shows that the above relation between $F(q_i, P_j, t)$ and $F(q_i, Q_j, t)$ amounts to a Legendre transformation.

The new Hamiltonian is

$$H'(P_j, Q_j, t) = H(p_i, q_i, t) + \frac{\partial}{\partial t} F(q_i, P_j, t).\tag{1.58}$$

Instead of (1.54) we could, of course, also have chosen functions with other mixtures of arguments such as $F(q_i, P_j, t)$, $F(p_i, Q_j, t)$, $F(p_i, P_j, t)$ to generate simple canonical transformations.

A particularly important canonical transformation arises by choosing a generating function $F(q_i, P_j)$ in such a way that it leads to time-independent momenta $P_j \equiv \alpha_j$. Coordinates Q_j with this property are called *cyclic*. To find cyclic coordinates we must search for a generating function $F(q_j, P_j, t)$ which makes the transformed H' in (1.58) vanish identically. Then all derivatives with respect to the coordinates vanish and the new momenta P_j are trivially constant. Thus we seek a solution of the equation

$$\frac{\partial}{\partial t} F(q_i, P_j, t) = -H(p_i, q_i, t), \quad (1.59)$$

where the momentum variables in the Hamiltonian obey the first equation of (1.57). This leads to the following partial differential equation for $F(q_i, P_j, t)$:

$$\partial_t F(q_i, P_j, t) = -H(\partial_{q_i} F(q_i, P_j, t), q_i, t), \quad (1.60)$$

called the *Hamilton-Jacobi equation*. Here and in the sequel we shall often use the short notations for partial derivatives $\partial_t \equiv \partial/\partial t$, $\partial_{q_i} \equiv \partial/\partial q_i$.

A generating function which achieves this goal is supplied by the action functional (1.14). When following the classical solutions starting from a fixed initial point and running to all possible final points q_i at a time t , the associated actions of these solutions form a function $A(q_i, t)$. Expression (1.14) show that if a particle moves along a classical trajectory, and the path is varied *without* keeping the endpoints fixed, the action changes as a function of the end positions (1.16) by

$$\delta \mathcal{A}[p_i, q_i] = p_i(t_b) \delta q_i(t_b) - p_i(t_a) \delta q_i(t_a). \quad (1.61)$$

From this we deduce immediately the first of the equations (1.57), now for the generating function $A(q_i, t)$:

$$p_i = \frac{\partial}{\partial q_i} A(q_i, t). \quad (1.62)$$

Moreover, the function $A(q_i, t)$ has the time derivative

$$\frac{d}{dt} A(q_i(t), t) = p_i(t) \dot{q}_i(t) - H(p_i(t), q_i(t), t). \quad (1.63)$$

Together with (1.62) this implies

$$\partial_t A(q_i, t) = -H(p_i, q_i, t). \quad (1.64)$$

If the momenta p_i on the right-hand side are replaced according to (1.62), $A(q_i, t)$ is indeed seen to be a solution of the Hamilton-Jacobi differential equation:

$$\partial_t A(q_i, t) = -H(\partial_{q_i} A(q_i, t), q_i, t). \quad (1.65)$$

1.2 Relativistic Mechanics in Curved Spacetime

The classical action of a relativistic spinless point particle in a curved four-dimensional spacetime is usually written as an integral

$$\mathcal{A} = -Mc^2 \int d\tau L(q, \dot{q}) = -Mc^2 \int d\tau \sqrt{g_{\mu\nu} \dot{q}^\mu(\tau) \dot{q}^\nu(\tau)}, \quad (1.66)$$

where τ is an arbitrary parameter of the trajectory. It can be chosen in the final trajectory to make $L(q, \dot{q}) \equiv 1$, in which case it coincides with the *proper time* of the particle. For arbitrary τ , the Euler-Lagrange equation (1.8) reads

$$\frac{d}{dt} \left[\frac{1}{L(q, \dot{q})} g_{\mu\nu} \dot{q}^\nu \right] = \frac{1}{2L(q, \dot{q})} (\partial_\mu g_{\kappa\lambda}) \dot{q}^\kappa \dot{q}^\lambda. \quad (1.67)$$

If τ is the proper time where $L(q, \dot{q}) \equiv 1$, this simplifies to

$$\frac{d}{dt} (g_{\mu\nu} \dot{q}^\nu) = \frac{1}{2} (\partial_\mu g_{\kappa\lambda}) \dot{q}^\kappa \dot{q}^\lambda, \quad (1.68)$$

or

$$g_{\mu\nu} \ddot{q}^\nu = \left(\frac{1}{2} \partial_\mu g_{\kappa\lambda} - \partial_\lambda g_{\mu\kappa} \right) \dot{q}^\kappa \dot{q}^\lambda. \quad (1.69)$$

For brevity, we have denoted partial derivatives $\partial/\partial q^\mu$ by ∂_μ . This partial derivative is supposed to apply only to the quantity right behind it. At this point one introduces the *Christoffel symbol*

$$\bar{\Gamma}_{\lambda\nu\mu} \equiv \frac{1}{2} (\partial_\lambda g_{\nu\mu} + \partial_\nu g_{\lambda\mu} - \partial_\mu g_{\lambda\nu}), \quad (1.70)$$

and the Christoffel symbol of the second kind³

$$\bar{\Gamma}_{\kappa\nu}{}^\mu \equiv g^{\mu\sigma} \bar{\Gamma}_{\kappa\nu\sigma}. \quad (1.71)$$

Then (1.69) can be written as

$$\ddot{q}^\mu + \bar{\Gamma}_{\kappa\lambda}{}^\mu \dot{q}^\kappa \dot{q}^\lambda = 0. \quad (1.72)$$

Since the solutions of this equation minimize the length of a curve in spacetime, they are called *geodesics*.

³In many textbooks, for instance S. Weinberg, *Gravitation and Cosmology*, Wiley, New York, 1972, the upper index and the third index in (1.70) stand at the first position. Our notation follows J.A. Schouten, *Ricci Calculus*, Springer, Berlin, 1954. It will allow for a closer analogy with gauge fields in the construction of the Riemann tensor as a covariant curl of the Christoffel symbol in Chapter 10. See H. Kleinert, *Gauge Fields in Condensed Matter*, Vol. II *Stresses and Defects*, World Scientific Publishing Co., Singapore 1989, pp. 744-1443 (<http://www.physik.fu-berlin.de/~kleinert/b2>).

1.3 Quantum Mechanics

Historically, the extension of classical mechanics to quantum mechanics became necessary in order to understand the stability of atomic orbits and the discrete nature of atomic spectra. It soon became clear that these phenomena reflect the fact that at a sufficiently short length scale, small material particles such as electrons behave like waves, called *material waves*. The fact that waves cannot be squeezed into an arbitrarily small volume without increasing indefinitely their frequency and thus their energy, prevents the collapse of the electrons into the nucleus, which would take place in classical mechanics. The discreteness of the atomic states of an electron are a manifestation of standing material waves in the atomic potential well, by analogy with the standing waves of electromagnetism in a cavity.

1.3.1 Bragg Reflections and Interference

The most direct manifestation of the wave nature of small particles is seen in diffraction experiments on periodic structures, for example of electrons diffracted by a crystal. If an electron beam of fixed momentum \mathbf{p} passes through a crystal, it emerges along sharply peaked angles. These are the well-known *Bragg reflections*. They look very similar to the interference patterns of electromagnetic waves. In fact, it is possible to use the same mathematical framework to explain these patterns as in electromagnetism. A free particle moving with momentum

$$\mathbf{p} = (p^1, p^2, \dots, p^D). \quad (1.73)$$

through a D -dimensional Euclidean space spanned by the Cartesian coordinate vectors

$$\mathbf{x} = (x^1, x^2, \dots, x^D) \quad (1.74)$$

is associated with a *plane wave*, whose field strength or *wave function* has the form

$$\Psi_{\mathbf{p}}(\mathbf{x}, t) = e^{i\mathbf{k}\mathbf{x} - i\omega t}, \quad (1.75)$$

where \mathbf{k} is the *wave vector* pointing into the direction of \mathbf{p} and ω is the *wave frequency*. Each scattering center, say at \mathbf{x}' , becomes a source of a spherical wave with the spatial behavior e^{ikR}/R (with $R \equiv |\mathbf{x} - \mathbf{x}'|$ and $k \equiv |\mathbf{k}|$) and the wavelength $\lambda = 2\pi/k$. At the detector, all field strengths have to be added to the total field strength $\Psi(\mathbf{x}, t)$. The absolute square of the total field strength, $|\Psi(\mathbf{x}, t)|^2$, is proportional to the number of electrons arriving at the detector.

The standard experiment where these rules can most simply be applied consists of an electron beam impinging vertically upon a flat screen with two parallel slits a with spacing d . At a large distance R behind these, one observes the number of particles arriving per unit time (see Fig. 1.1)

$$\frac{dN}{dt} \propto |\Psi_1 + \Psi_2|^2 \approx \left| e^{ik(R + \frac{1}{2}d \sin \varphi)} + e^{ik(R - \frac{1}{2}d \sin \varphi)} \right|^2 \frac{1}{R^2}, \quad (1.76)$$

Figure 1.1 Probability distribution of particle behind double slit, being proportional to the absolute square of the sum of the two complex field strengths.

where φ is the angle of deflection from the normal.

Conventionally, the wave function $\Psi(\mathbf{x}, t)$ is normalized to describe a single particle. Its absolute square gives directly the probability density of the particle at the place \mathbf{x} in space, i.e., $d^3x |\Psi(\mathbf{x}, t)|^2$ is the probability of finding the particle in the volume element d^3x around \mathbf{x} .

1.3.2 Matter Waves

From the experimentally observed relation between the momentum and the size of the angular deflection φ of the diffracted beam of the particles, one deduces the relation between momentum and wave vector

$$\mathbf{p} = \hbar \mathbf{k}, \quad (1.77)$$

where \hbar is the universal *Planck constant* whose dimension is equal to that of an action,

$$\hbar \equiv \frac{h}{2\pi} = 1.0545919(80) \times 10^{-27} \text{erg sec} \quad (1.78)$$

(the number in parentheses indicating the experimental uncertainty of the last two digits before it). A similar relation holds between the energy and the frequency of the wave $\Psi(\mathbf{x}, t)$. It may be determined by an absorption process in which a light wave hits an electron and kicks it out of the surface of a metal, the well-known *photoelectric effect*. From the threshold property of this effect one learns that an electromagnetic wave oscillating in time as $e^{-i\omega t}$ can transfer to the electron the energy

$$E = \hbar \omega, \quad (1.79)$$

where the proportionality constant \hbar is the same as in (1.77). The reason for this lies in the properties of electromagnetic waves. On the one hand, their frequency ω and the wave vector \mathbf{k} satisfy the relation $\omega/c = |\mathbf{k}|$, where c is the light velocity

defined to be $c \equiv 299\,792.458$ km/s. On the other hand, energy and momentum are related by $E/c = |\mathbf{p}|$. Thus, the quanta of electromagnetic waves, the *photons*, certainly satisfy (1.77) and the constant \hbar must be the same as in Eq. (1.79).

With matter waves and photons sharing the same relations (1.77), it is suggestive to postulate also the relation (1.79) between energy and frequency to be universal for the waves of all particles, massive and massless ones. All free particles of momentum \mathbf{p} are described by a *plane wave* of wavelength $\lambda = 2\pi/|\mathbf{k}| = 2\pi\hbar/|\mathbf{p}|$, with the explicit form

$$\Psi_{\mathbf{p}}(\mathbf{x}, t) = \mathcal{N} e^{i(\mathbf{p}\mathbf{x} - E_{\mathbf{p}}t)/\hbar}, \quad (1.80)$$

where \mathcal{N} is some normalization constant. In a finite volume, the wave function is normalized to unity. In an infinite volume, this normalization makes the wave function vanish. To avoid this, the *current density* of the particle probability

$$\mathbf{j}(\mathbf{x}, t) \equiv -i \frac{\hbar}{2m} \psi^*(\mathbf{x}, t) \overleftrightarrow{\nabla} \psi(\mathbf{x}, t) \quad (1.81)$$

is normalized in some convenient way, where $\overleftrightarrow{\nabla}$ is a short notation for the difference between forward- and backward-derivatives

$$\begin{aligned} \psi^*(\mathbf{x}, t) \overleftrightarrow{\nabla} \psi(\mathbf{x}, t) &\equiv \psi^*(\mathbf{x}, t) \overrightarrow{\nabla} \psi(\mathbf{x}, t) - \psi^*(\mathbf{x}, t) \overleftarrow{\nabla} \psi(\mathbf{x}, t) \\ &\equiv \psi^*(\mathbf{x}, t) \nabla \psi(\mathbf{x}, t) - [\nabla \psi^*(\mathbf{x}, t)] \psi(\mathbf{x}, t). \end{aligned} \quad (1.82)$$

The energy $E_{\mathbf{p}}$ depends on the momentum of the particle in the classical way, i.e., for nonrelativistic material particles of mass M it is $E_{\mathbf{p}} = \mathbf{p}^2/2M$, for relativistic ones $E_{\mathbf{p}} = c\sqrt{\mathbf{p}^2 + M^2c^2}$, and for massless particles such as photons $E_{\mathbf{p}} = c|\mathbf{p}|$. The common relation $E_{\mathbf{p}} = \hbar\omega$ for photons and matter waves is necessary to guarantee conservation of energy in quantum mechanics.

In general, both momentum and energy of a particle are not sharply defined as in the plane-wave function (1.80). Usually, a particle wave is some superposition of plane waves (1.80)

$$\Psi(\mathbf{x}, t) = \int \frac{d^3p}{(2\pi\hbar)^3} f(\mathbf{p}) e^{i(\mathbf{p}\mathbf{x} - E_{\mathbf{p}}t)/\hbar}. \quad (1.83)$$

By the Fourier inversion theorem, $f(\mathbf{p})$ can be calculated via the integral

$$f(\mathbf{p}) = \int d^3x e^{-i\mathbf{p}\mathbf{x}/\hbar} \Psi(\mathbf{x}, 0). \quad (1.84)$$

With an appropriate choice of $f(\mathbf{p})$ it is possible to prepare $\Psi(\mathbf{x}, t)$ in any desired form at some initial time, say at $t = 0$. For example, $\Psi(\mathbf{x}, 0)$ may be a function sharply centered around a space point $\bar{\mathbf{x}}$. Then $f(\mathbf{p})$ is approximately a pure phase $f(\mathbf{p}) \sim e^{-i\mathbf{p}\bar{\mathbf{x}}/\hbar}$, and the wave contains all momenta with equal probability. Conversely, if the particle amplitude is spread out in space, its momentum distribution is confined to a small region. The limiting $f(\mathbf{p})$ is concentrated at a specific momentum $\bar{\mathbf{p}}$. The particle is found at each point in space with equal probability, with the amplitude oscillating like $\Psi(\mathbf{x}, t) \sim e^{i(\bar{\mathbf{p}}\mathbf{x} - E_{\bar{\mathbf{p}}}t)/\hbar}$.

In general, the width of $\Psi(\mathbf{x}, 0)$ in space and of $f(\mathbf{p})$ in momentum space are inversely proportional to each other:

$$\Delta \mathbf{x} \Delta \mathbf{p} \sim \hbar. \quad (1.85)$$

This is the content of *Heisenberg's principle of uncertainty*. If the wave is localized in a finite region of space while having at the same time a fairly well-defined average momentum $\bar{\mathbf{p}}$, it is called a *wave packet*. The maximum in the associated probability density can be shown from (1.83) to move with a velocity

$$\bar{\mathbf{v}} = \partial E_{\bar{\mathbf{p}}} / \partial \bar{\mathbf{p}}. \quad (1.86)$$

This coincides with the velocity of a classical particle of momentum $\bar{\mathbf{p}}$.

1.3.3 Schrödinger Equation

Suppose now that the particle is nonrelativistic and has a mass M . The classical Hamiltonian, and thus the energy $E_{\mathbf{p}}$, are given by

$$H(\mathbf{p}) = E_{\mathbf{p}} = \frac{\mathbf{p}^2}{2M}. \quad (1.87)$$

We may therefore derive the following identity for the wave field $\Psi_{\mathbf{p}}(\mathbf{x}, t)$:

$$\int \frac{d^3 p}{(2\pi\hbar)^3} f(\mathbf{p}) [H(\mathbf{p}) - E_{\mathbf{p}}] e^{i(\mathbf{p}\mathbf{x} - E_{\mathbf{p}}t)/\hbar} = 0. \quad (1.88)$$

The arguments *inside* the brackets can be removed from the integral by observing that \mathbf{p} and $E_{\mathbf{p}}$ inside the integral are equivalent to the differential operators

$$\begin{aligned} \hat{\mathbf{p}} &= -i\hbar\nabla, \\ \hat{E} &= i\hbar\partial_t \end{aligned} \quad (1.89)$$

outside. Then, Eq. (1.88) may be written as the differential equation

$$[H(-i\hbar\nabla) - i\hbar\partial_t]\Psi(\mathbf{x}, t) = 0. \quad (1.90)$$

This is the *Schrödinger equation* for the wave function of a free particle. The equation suggests that the motion of a particle with an arbitrary Hamiltonian $H(\mathbf{p}, \mathbf{x}, t)$ follows the straightforward generalization of (1.90)

$$(\hat{H} - i\hbar\partial_t)\Psi(\mathbf{x}, t) = 0, \quad (1.91)$$

where \hat{H} is the differential operator

$$\hat{H} \equiv H(-i\hbar\nabla, \mathbf{x}, t). \quad (1.92)$$

The rule of obtaining \hat{H} from the classical Hamiltonian $H(\mathbf{p}, \mathbf{x}, t)$ by the substitution $\mathbf{p} \rightarrow \hat{\mathbf{p}} = -i\hbar\nabla$ will be referred to as the *correspondence principle*.⁴ We shall see in Sections 1.13–1.15 that this simple correspondence principle holds only in Cartesian coordinates.

The Schrödinger operators (1.89) of momentum and energy satisfy with \mathbf{x} and t the so-called canonical commutation relations

$$[\hat{p}_i, x_j] = -i\hbar, \quad [\hat{E}, t] = 0 = i\hbar. \quad (1.93)$$

The linear combinations of the solutions of the Schrödinger equation (1.91) form, at each time t , a *Hilbert space*. If the Hamiltonian does not depend explicitly on time, If the Hamiltonian does not depend explicitly on time, the Hilbert space can be spanned by the energy eigenstates $\Psi_{E_n}(\mathbf{x}, t) = e^{-iE_n t/\hbar}\Psi_{E_n}(\mathbf{x})$, where $\Psi_{E_n}(\mathbf{x})$ are time-independent *stationary states*, which solve the time-independent Schrödinger equation

$$\hat{H}(\hat{\mathbf{p}}, \mathbf{x})\Psi_{E_n}(\mathbf{x}) = E_n\Psi_{E_n}(\mathbf{x}). \quad (1.94)$$

The validity of the Schrödinger theory (1.91) is confirmed by experiment, most notably for the Coulomb Hamiltonian

$$H(\mathbf{p}, \mathbf{x}) = \frac{\mathbf{p}^2}{2M} - \frac{e^2}{r}, \quad (1.95)$$

which governs the quantum mechanics of the hydrogen atom in the center-of-mass coordinate system of electron and proton, where M is the reduced mass of the two particles.

Since the square of the wave function, $|\Psi(\mathbf{x}, t)|^2$, is interpreted as the probability density of a single particle in a finite volume, the integral over the entire volume must be normalized to unity:

$$\int d^3x |\Psi(\mathbf{x}, t)|^2 = 1. \quad (1.96)$$

For a stable particle, this normalization must remain the same at all times. If $\Psi(\mathbf{x}, t)$ is to follow the Schrödinger equation (1.91), this is assured if and only if the Hamiltonian operator is Hermitian,⁵ i.e., if it satisfies for arbitrary wave functions Ψ_1, Ψ_2 the equality

$$\int d^3x [\hat{H}\Psi_2(\mathbf{x}, t)]^*\Psi_1(\mathbf{x}, t) = \int d^3x \Psi_2^*(\mathbf{x}, t)\hat{H}\Psi_1(\mathbf{x}, t). \quad (1.97)$$

⁴Our formulation of this principle is slightly stronger than the historical one used in the initial phase of quantum mechanics, which gave certain translation rules between classical and quantum-mechanical relations. The substitution rule for the momentum runs also under the name *Jordan rule*.

⁵Problems arising from unboundedness or discontinuities of the Hamiltonian and other quantum-mechanical operators, such as restrictions of the domains of definition, are ignored here since they are well understood. Correspondingly we do not distinguish between Hermitian and self-adjoint operators (see J. v. Neumann, *Mathematische Grundlagen der Quantenmechanik*, Springer, Berlin, 1932). Some quantum-mechanical operator subtleties will manifest themselves in this book as problems of path integration to be solved in Chapter 12. The precise relationship between the two calls for further detailed investigations.

The left-hand side defines the *Hermitian-adjoint* \hat{H}^\dagger of the operator \hat{H} , which satisfies the identity

$$\int d^3x \Psi_2^*(\mathbf{x}, t) \hat{H}^\dagger \Psi_1(\mathbf{x}, t) \equiv \int d^3x [\hat{H} \Psi_2(\mathbf{x}, t)]^* \Psi_1(\mathbf{x}, t) \quad (1.98)$$

for all wave functions $\Psi_1(\mathbf{x}, t)$, $\Psi_2(\mathbf{x}, t)$. An operator \hat{H} is *Hermitian*, if it coincides with its Hermitian-adjoint \hat{H}^\dagger :

$$\hat{H} = \hat{H}^\dagger. \quad (1.99)$$

Let us calculate the time change of the integral over two arbitrary wave functions, $\int d^3x \Psi_2^*(\mathbf{x}, t) \Psi_1(\mathbf{x}, t)$. With the Schrödinger equation (1.91), this time change vanishes indeed as long as \hat{H} is Hermitian:

$$\begin{aligned} & i\hbar \frac{d}{dt} \int d^3x \Psi_2^*(\mathbf{x}, t) \Psi_1(\mathbf{x}, t) \\ &= \int d^3x \Psi_2^*(\mathbf{x}, t) \hat{H} \Psi_1(\mathbf{x}, t) - \int d^3x [\hat{H} \Psi_2(\mathbf{x}, t)]^* \Psi_1(\mathbf{x}, t) = 0. \end{aligned} \quad (1.100)$$

This also implies the time independence of the normalization integral $\int d^3x |\Psi(\mathbf{x}, t)|^2 = 1$.

Conversely, if \hat{H} is not Hermitian, one can always find an eigenstate of \hat{H} whose norm changes with time: any eigenstate of $(\hat{H} - \hat{H}^\dagger)/i$ has this property.

Since $\hat{\mathbf{p}} = -i\hbar \nabla$ and \mathbf{x} are themselves Hermitian operators, \hat{H} will automatically be a Hermitian operator if it is a sum of a kinetic and a potential energy:

$$H(\mathbf{p}, \mathbf{x}, t) = T(\mathbf{p}, t) + V(\mathbf{x}, t). \quad (1.101)$$

This is always the case for nonrelativistic particles in Cartesian coordinates \mathbf{x} . If \mathbf{p} and \mathbf{x} appear in one and the same term of H , for instance as $\mathbf{p}^2 \mathbf{x}^2$, the correspondence principle does not lead to a unique quantum-mechanical operator \hat{H} . Then there seem to be, in principle, several Hermitian operators which, in the above example, can be constructed from the product of two $\hat{\mathbf{p}}$ and two $\hat{\mathbf{x}}$ operators [for instance $\alpha \hat{\mathbf{p}}^2 \hat{\mathbf{x}}^2 + \beta \hat{\mathbf{x}}^2 \hat{\mathbf{p}}^2 + \gamma \hat{\mathbf{p}} \hat{\mathbf{x}}^2 \hat{\mathbf{p}}$ with $\alpha + \beta + \gamma = 1$]. They all correspond to the same classical $\mathbf{p}^2 \mathbf{x}^2$. At first sight it appears as though only a comparison with experiment could select the correct operator ordering. This is referred to as the operator-ordering problem of *quantum mechanics* which has plagued many researchers in the past. If the ordering problem is caused by the geometry of the space in which the particle moves, there exists a surprisingly simple geometric principle which specifies the ordering in the physically correct way. Before presenting this in Chapter 10 we shall avoid ambiguities by assuming $H(\mathbf{p}, \mathbf{x}, t)$ to have the standard form (1.101), unless otherwise stated.

1.3.4 Particle Current Conservation

The conservation of the total probability (1.96) is a consequence of a more general *local conservation law* linking the *current density* of the particle probability

$$\mathbf{j}(\mathbf{x}, t) \equiv -i \frac{\hbar}{2m} \psi(\mathbf{x}, t) \overleftrightarrow{\nabla} \psi(\mathbf{x}, t) \quad (1.102)$$

with the *probability density*

$$\rho(\mathbf{x}, t) = \psi^*(\mathbf{x}, t) \psi(\mathbf{x}, t) \quad (1.103)$$

via the relation

$$\partial_t \rho(\mathbf{x}, t) = -\nabla \cdot \mathbf{j}(\mathbf{x}, t). \quad (1.104)$$

By integrating this *current conservation law* over a volume V enclosed by a surface S , and using Green's theorem, one finds

$$\int_V d^3x \partial_t \rho(\mathbf{x}, t) = - \int_V d^3x \nabla \cdot \mathbf{j}(\mathbf{x}, t) = - \int_S d\mathbf{S} \cdot \mathbf{j}(\mathbf{x}, t), \quad (1.105)$$

where $d\mathbf{S}$ are the directed infinitesimal surface elements. This equation states that the probability in a volume decreases by the same amount by which probability leaves the surface via the current $\mathbf{j}(\mathbf{x}, t)$.

By extending the integral (1.105) over the entire space and assuming the currents to vanish at spatial infinity, we recover the conservation of the total probability (1.96).

More general dynamical systems with N particles in Euclidean space are parametrized in terms of $3N$ Cartesian coordinates \mathbf{x}_ν ($\nu = 1, \dots, N$). The Hamiltonian has the form

$$H(\mathbf{p}_\nu, \mathbf{x}_\nu, t) = \sum_{\nu=1}^N \frac{\mathbf{p}_\nu^2}{2M_\nu} + V(\mathbf{x}_\nu, t), \quad (1.106)$$

where the arguments $\mathbf{p}_\nu, \mathbf{x}_\nu$ in H and V stand for all \mathbf{p}_ν 's, \mathbf{x}_ν with $\nu = 1, 2, 3, \dots, N$. The wave function $\Psi(\mathbf{x}_\nu, t)$ satisfies the N -particle Schrödinger equation

$$\left\{ - \sum_{\nu=1}^N \left[\frac{\hbar^2}{2M_\nu} \partial_{\mathbf{x}_\nu}^2 + V(\mathbf{x}_\nu, t) \right] \right\} \Psi(\mathbf{x}_\nu, t) = i\hbar \partial_t \Psi(\mathbf{x}_\nu, t). \quad (1.107)$$

1.4 Dirac's Bra-Ket Formalism

Mathematically speaking, the wave function $\Psi(\mathbf{x}, t)$ may be considered as a vector in an infinite-dimensional complex vector space called *Hilbert space*. The configuration space variable \mathbf{x} plays the role of a continuous "index" of these vectors. An obvious contact with the usual vector notation may be established, in which a D -dimensional vector \mathbf{v} is given in terms of its components v_i with a subscript $i = 1, \dots, D$, by writing the argument \mathbf{x} of $\Psi(\mathbf{x}, t)$ as a subscript:

$$\Psi(\mathbf{x}, t) \equiv \Psi_{\mathbf{x}}(t). \quad (1.108)$$

The usual norm of a complex vector is defined by

$$|\mathbf{v}|^2 = \sum_i v_i^* v_i. \quad (1.109)$$

The continuous version of this is

$$|\Psi|^2 = \int d^3x \Psi_{\mathbf{x}}^*(t) \Psi_{\mathbf{x}}(t) = \int d^3x \Psi^*(\mathbf{x}, t) \Psi(\mathbf{x}, t). \quad (1.110)$$

The normalization condition (1.96) requires that the wave functions have the norm $|\Psi| = 1$, i.e., that they are unit vectors in the Hilbert space.

1.4.1 Basis Transformations

In a vector space, there are many possible choices of orthonormal basis vectors b_i^a labeled by $a = 1, \dots, D$, in terms of which⁶

$$v_i = \sum_a b_i^a v_a, \quad (1.111)$$

with the components v_a given by the scalar products

$$v_a \equiv \sum_i b_i^{a*} v_i. \quad (1.112)$$

The latter equation is a consequence of the *orthogonality relation*⁷

$$\sum_i b_i^{a*} b_i^{a'} = \delta^{aa'}, \quad (1.113)$$

which in a finite-dimensional vector space implies the *completeness relation*

$$\sum_a b_i^{a*} b_j^a = \delta^{ij}. \quad (1.114)$$

In the space of wave functions (1.108) there exists a special set of basis functions called *local basis functions* of particular importance. It may be constructed in the following fashion: Imagine the continuum of space points to be coarse-grained into a cubic lattice of mesh size ϵ , at positions

$$\mathbf{x}_{\mathbf{n}} = (n_1, n_2, n_3)\epsilon, \quad n_{1,2,3} = 0, \pm 1, \pm 2, \dots \quad (1.115)$$

Let $h^{\mathbf{n}}(\mathbf{x})$ be a function that vanishes everywhere in space, except in a cube of size ϵ^3 centered around $\mathbf{x}_{\mathbf{n}}$, i.e., for each component x_i of \mathbf{x} ,

$$h^{\mathbf{n}}(\mathbf{x}) = \begin{cases} 1/\sqrt{\epsilon^3} & |x_i - x_{\mathbf{n}i}| \leq \epsilon/2, \quad i = 1, 2, 3. \\ 0 & \text{otherwise.} \end{cases} \quad (1.116)$$

⁶Mathematicians would expand more precisely $v_i = \sum_a b_i^a v_a^{(b)}$, but physicists prefer to shorten the notation by distinguishing the different components via different types of subscripts, using for the initial components i, j, k, \dots and for the b -transformed components a, b, c, \dots .

⁷An orthogonality relation implies usually a unit norm and is thus really an *orthonormality relation* but this name is rarely used.

These functions are certainly orthonormal:

$$\int d^3x h^{\mathbf{n}}(\mathbf{x})^* h^{\mathbf{n}'}(\mathbf{x}) = \delta^{\mathbf{nn}'}. \quad (1.117)$$

Consider now the expansion

$$\Psi(\mathbf{x}, t) = \sum_{\mathbf{n}} h^{\mathbf{n}}(\mathbf{x}) \Psi_{\mathbf{n}}(t) \quad (1.118)$$

with the coefficients

$$\Psi_{\mathbf{n}}(t) = \int d^3x h^{\mathbf{n}}(\mathbf{x})^* \Psi(\mathbf{x}, t) \approx \sqrt{\epsilon^3} \Psi(\mathbf{x}_{\mathbf{n}}, t). \quad (1.119)$$

It provides an excellent approximation to the true wave function $\Psi(\mathbf{x}, t)$, as long as the mesh size ϵ is much smaller than the scale over which $\Psi(\mathbf{x}, t)$ varies. In fact, if $\Psi(\mathbf{x}, t)$ is integrable, the integral over the sum (1.118) will always converge to $\Psi(\mathbf{x}, t)$. The same convergence of discrete approximations is found in any scalar product, and thus in any observable probability amplitudes. They can all be calculated with arbitrary accuracy knowing the discrete components of the type (1.119) in the limit $\epsilon \rightarrow 0$. The functions $h^{\mathbf{n}}(\mathbf{x})$ may therefore be used as an approximate basis in the same way as the previous basis functions $f^a(\mathbf{x}), g^b(\mathbf{x})$, with any desired accuracy depending on the choice of ϵ .

In general, there are many possible orthonormal basis functions $f^a(\mathbf{x})$ in the Hilbert space which satisfy the orthonormality relation

$$\int d^3x f^a(\mathbf{x})^* f^{a'}(\mathbf{x}) = \delta^{aa'}, \quad (1.120)$$

in terms of which we can expand

$$\Psi(\mathbf{x}, t) = \sum_a f^a(\mathbf{x}) \Psi_a(t), \quad (1.121)$$

with the coefficients

$$\Psi_a(t) = \int d^3x f^a(\mathbf{x})^* \Psi(\mathbf{x}, t). \quad (1.122)$$

Suppose we use another orthonormal basis $\tilde{f}^b(\mathbf{x})$ with the orthonormality relation

$$\int d^3x \tilde{f}^b(\mathbf{x})^* \tilde{f}^{b'}(\mathbf{x}) = \delta^{bb'}, \quad \sum_b \tilde{f}^b(\mathbf{x}) \tilde{f}^b(\mathbf{x}')^* = \delta^{(3)}(\mathbf{x} - \mathbf{x}'), \quad (1.123)$$

to re-expand

$$\Psi(\mathbf{x}, t) = \sum_b \tilde{f}^b(\mathbf{x}) \tilde{\Psi}_b(t), \quad (1.124)$$

with the components

$$\tilde{\Psi}_b(t) = \int d^3x \tilde{f}^b(\mathbf{x})^* \Psi(\mathbf{x}, t). \quad (1.125)$$

Inserting (1.121) shows that the components are related to each other by

$$\tilde{\Psi}_b(t) = \sum_a \left[\int d^3x \tilde{f}^b(\mathbf{x})^* f^a(\mathbf{x}) \right] \Psi_a(t). \quad (1.126)$$

1.4.2 Bracket Notation

It is useful to write the scalar products between two wave functions occurring in the above basis transformations in the so-called *bracket notation* as

$$\langle \tilde{b}|a\rangle \equiv \int d^3x \tilde{f}^b(\mathbf{x})^* f^a(\mathbf{x}). \quad (1.127)$$

In this notation, the components of the state vector $\Psi(\mathbf{x}, t)$ in (1.122), (1.125) are

$$\begin{aligned} \Psi_a(t) &= \langle a|\Psi(t)\rangle, \\ \tilde{\Psi}_b(t) &= \langle \tilde{b}|\Psi(t)\rangle. \end{aligned} \quad (1.128)$$

The transformation formula (1.126) takes the form

$$\langle \tilde{b}|\Psi(t)\rangle = \sum_a \langle \tilde{b}|a\rangle \langle a|\Psi(t)\rangle. \quad (1.129)$$

The right-hand side of this equation may be formally viewed as a result of inserting the abstract relation

$$\sum_a |a\rangle \langle a| = 1 \quad (1.130)$$

between $\langle \tilde{b}|$ and $|\Psi(t)\rangle$ on the left-hand side:

$$\langle \tilde{b}|\Psi(t)\rangle = \langle \tilde{b}|1|\Psi(t)\rangle = \sum_a \langle \tilde{b}|a\rangle \langle a|\Psi(t)\rangle. \quad (1.131)$$

Since this expansion is only possible if the functions $f^b(\mathbf{x})$ form a complete basis, the relation (1.130) is alternative, abstract way of stating the completeness of the basis functions. It may be referred to as completeness relation à la Dirac.

Since the scalar products are written in the form of brackets $\langle a|a'\rangle$, Dirac called the formal objects $\langle a|$ and $|a'\rangle$, from which the brackets are composed, *bra* and *ket*, respectively. In the bracket notation, the orthonormality of the basis $f^a(\mathbf{x})$ and $g^b(\mathbf{x})$ may be expressed as follows:

$$\begin{aligned} \langle a|a'\rangle &= \int d^3x f^a(\mathbf{x})^* f^{a'}(\mathbf{x}) = \delta^{aa'}, \\ \langle \tilde{b}|\tilde{b}'\rangle &= \int d^3x \tilde{f}^b(\mathbf{x})^* \tilde{f}^{b'}(\mathbf{x}) = \delta^{bb'}. \end{aligned} \quad (1.132)$$

In the same spirit we introduce abstract bra and ket vectors associated with the basis functions $h^n(\mathbf{x})$ of Eq. (1.116), denoting them by $\langle \mathbf{x}_n|$ and $|\mathbf{x}_n\rangle$, respectively, and writing the orthogonality relation (1.117) in bracket notation as

$$\langle \mathbf{x}_n|\mathbf{x}_{n'}\rangle \equiv \int d^3x h^n(\mathbf{x})^* h^{n'}(\mathbf{x}) = \delta_{nn'}. \quad (1.133)$$

The components $\Psi_n(t)$ may be considered as the scalar products

$$\Psi_n(t) \equiv \langle \mathbf{x}_n|\Psi(t)\rangle \approx \sqrt{\epsilon^3} \Psi(\mathbf{x}_n, t). \quad (1.134)$$

Changes of basis vectors, for instance from $|\mathbf{x}_n\rangle$ to the states $|a\rangle$, can be performed according to the rules developed above by inserting a completeness relation à la Dirac of the type (1.130). Thus we may expand

$$\Psi_n(t) = \langle \mathbf{x}_n | \Psi(t) \rangle = \sum_a \langle \mathbf{x}_n | a \rangle \langle a | \Psi(t) \rangle. \quad (1.135)$$

Also the inverse relation is true:

$$\langle a | \Psi(t) \rangle = \sum_n \langle a | \mathbf{x}_n \rangle \langle \mathbf{x}_n | \Psi(t) \rangle. \quad (1.136)$$

This is, of course, just an approximation to the integral

$$\int d^3x h^n(\mathbf{x})^* \langle \mathbf{x} | \Psi(t) \rangle. \quad (1.137)$$

The completeness of the basis $h^n(\mathbf{x})$ may therefore be expressed via the abstract relation

$$\sum_n |\mathbf{x}_n\rangle \langle \mathbf{x}_n| \approx 1. \quad (1.138)$$

The approximate sign turns into an equality sign in the limit of zero mesh size, $\epsilon \rightarrow 0$.

1.4.3 Continuum Limit

In ordinary calculus, finer and finer sums are eventually replaced by integrals. The same thing is done here. We define new continuous scalar products

$$\langle \mathbf{x} | \Psi(t) \rangle \approx \frac{1}{\sqrt{\epsilon^3}} \langle \mathbf{x}_n | \Psi(t) \rangle, \quad (1.139)$$

where \mathbf{x}_n are the lattice points closest to \mathbf{x} . With (1.134), the right-hand side is equal to $\Psi(\mathbf{x}_n, t)$. In the limit $\epsilon \rightarrow 0$, \mathbf{x} and \mathbf{x}_n coincide and we have

$$\langle \mathbf{x} | \Psi(t) \rangle \equiv \Psi(\mathbf{x}, t). \quad (1.140)$$

The completeness relation can be used to write

$$\begin{aligned} \langle a | \Psi(t) \rangle &\approx \sum_n \langle a | \mathbf{x}_n \rangle \langle \mathbf{x}_n | \Psi(t) \rangle \\ &\approx \sum_n \epsilon^3 \langle a | \mathbf{x} \rangle \langle \mathbf{x} | \Psi(t) \rangle \Big|_{\mathbf{x}=\mathbf{x}_n}, \end{aligned} \quad (1.141)$$

which in the limit $\epsilon \rightarrow 0$ becomes

$$\langle a | \Psi(t) \rangle = \int d^3x \langle a | \mathbf{x} \rangle \langle \mathbf{x} | \Psi(t) \rangle. \quad (1.142)$$

This may be viewed as the result of inserting the formal completeness relation of the limiting local bra and ket basis vectors $\langle \mathbf{x} |$ and $|\mathbf{x}\rangle$,

$$\int d^3x |\mathbf{x}\rangle \langle \mathbf{x}| = 1, \quad (1.143)$$

evaluated between the vectors $\langle a|$ and $|\Psi(t)\rangle$.

With the limiting local basis, the wave functions can be treated as components of the state vectors $|\Psi(t)\rangle$ with respect to the local basis $|\mathbf{x}\rangle$ in the same way as any other set of components in an arbitrary basis $|a\rangle$. In fact, the expansion

$$\langle a|\Psi(t)\rangle = \int d^3x \langle a|\mathbf{x}\rangle \langle \mathbf{x}|\Psi(t)\rangle \quad (1.144)$$

may be viewed as a re-expansion of a component of $|\Psi(t)\rangle$ in one basis, $|a\rangle$, into those of another basis, $|\mathbf{x}\rangle$, just as in (1.129).

In order to express all these transformation properties in a most compact notation, it has become customary to deal with an arbitrary physical state vector in a *basis-independent* way and denote it by a ket vector $|\Psi(t)\rangle$. This vector may be specified in any convenient basis by multiplying it with the corresponding completeness relation

$$\sum_a |a\rangle \langle a| = 1, \quad (1.145)$$

resulting in the expansion

$$|\Psi(t)\rangle = \sum_a |a\rangle \langle a|\Psi(t)\rangle. \quad (1.146)$$

This can be multiplied with any bra vector, say $\langle b|$, from the left to obtain the expansion formula (1.131):

$$\langle b|\Psi(t)\rangle = \sum_a \langle b|a\rangle \langle a|\Psi(t)\rangle. \quad (1.147)$$

The continuum version of the completeness relation (1.138) reads

$$\int d^3x |\mathbf{x}\rangle \langle \mathbf{x}| = 1, \quad (1.148)$$

and leads to the expansion

$$|\Psi(t)\rangle = \int d^3x |\mathbf{x}\rangle \langle \mathbf{x}|\Psi(t)\rangle, \quad (1.149)$$

in which the wave function $\Psi(\mathbf{x}, t) = \langle \mathbf{x}|\Psi(t)\rangle$ plays the role of an \mathbf{x} th component of the state vector $|\Psi(t)\rangle$ in the local basis $|\mathbf{x}\rangle$. This, in turn, is the limit of the discrete basis vectors $|\mathbf{x}_n\rangle$,

$$|\mathbf{x}\rangle \approx \frac{1}{\sqrt{\epsilon^3}} |\mathbf{x}_n\rangle, \quad (1.150)$$

with \mathbf{x}_n being the lattice points closest to \mathbf{x} .

A vector can be described equally well in bra or in ket form. To apply the above formalism consistently, we observe that the scalar products

$$\begin{aligned} \langle a|\tilde{b}\rangle &= \int d^3x f^a(\mathbf{x})^* \tilde{f}^b(\mathbf{x}), \\ \langle \tilde{b}|a\rangle &= \int d^3x \tilde{f}^b(\mathbf{x})^* f^a(\mathbf{x}) \end{aligned} \quad (1.151)$$

satisfy the identity

$$\langle \tilde{b} | a \rangle \equiv \langle a | \tilde{b} \rangle^*. \quad (1.152)$$

Therefore, when expanding a ket vector as

$$|\Psi(t)\rangle = \sum_a |a\rangle \langle a | \Psi(t)\rangle, \quad (1.153)$$

or a bra vector as

$$\langle \Psi(t) | = \sum_a \langle \Psi(t) | a \rangle \langle a |, \quad (1.154)$$

a multiplication of the first equation with the bra $\langle \mathbf{x} |$ and of the second with the ket $|\mathbf{x}\rangle$ produces equations which are complex-conjugate to each other.

1.4.4 Generalized Functions

Dirac's bra-ket formalism is elegant and easy to handle. As far as the vectors $|\mathbf{x}\rangle$ are concerned there is, however, one inconsistency with some fundamental postulates of quantum mechanics: When introducing state vectors, the norm was required to be unity in order to permit a proper probability interpretation of single-particle states. The limiting states $|\mathbf{x}\rangle$ introduced above do not satisfy this requirement. In fact, the scalar product between two different states $\langle \mathbf{x} |$ and $|\mathbf{x}'\rangle$ is

$$\langle \mathbf{x} | \mathbf{x}' \rangle \approx \frac{1}{\epsilon^3} \langle \mathbf{x}_n | \mathbf{x}_{n'} \rangle = \frac{1}{\epsilon^3} \delta_{\mathbf{nn}'}, \quad (1.155)$$

where \mathbf{x}_n and $\mathbf{x}_{n'}$ are the lattice points closest to \mathbf{x} and \mathbf{x}' . For $\mathbf{x} \neq \mathbf{x}'$, the states are orthogonal. For $\mathbf{x} = \mathbf{x}'$, on the other hand, the limit $\epsilon \rightarrow 0$ is infinite, approached in such a way that

$$\epsilon^3 \sum_{\mathbf{n}'} \frac{1}{\epsilon^3} \delta_{\mathbf{nn}'} = 1. \quad (1.156)$$

Therefore, the limiting state $|\mathbf{x}\rangle$ is not a properly normalizable vector in the Hilbert space. For the sake of elegance, it is useful to weaken the requirement of normalizability (1.96) by admitting the limiting states $|\mathbf{x}\rangle$ to the physical Hilbert space. In fact, one admits all states which can be obtained by a limiting sequence from properly normalized state vectors.

The scalar product between states $\langle \mathbf{x} | \mathbf{x}' \rangle$ is not a proper function. It is denoted by the symbol $\delta^{(3)}(\mathbf{x} - \mathbf{x}')$ and called *Dirac δ -function*:

$$\langle \mathbf{x} | \mathbf{x}' \rangle \equiv \delta^{(3)}(\mathbf{x} - \mathbf{x}'). \quad (1.157)$$

The right-hand side vanishes everywhere, except in the infinitely small box of width ϵ around $\mathbf{x} \approx \mathbf{x}'$. Thus the δ -function satisfies

$$\delta^{(3)}(\mathbf{x} - \mathbf{x}') = 0 \quad \text{for} \quad \mathbf{x} \neq \mathbf{x}'. \quad (1.158)$$

At $\mathbf{x} = \mathbf{x}'$, it is so large that its volume integral is unity:

$$\int d^3x' \delta^{(3)}(\mathbf{x} - \mathbf{x}') = 1. \quad (1.159)$$

Obviously, there exists no proper function that can satisfy both requirements, (1.158) and (1.159). Only the finite- ϵ approximation in (1.155) to the δ -function are proper functions. In this respect, the scalar product $\langle \mathbf{x} | \mathbf{x}' \rangle$ behaves just like the states $|\mathbf{x}\rangle$ themselves: Both are $\epsilon \rightarrow 0$ -limits of properly defined mathematical objects.

Note that the integral Eq. (1.159) implies the following property of the δ - function:

$$\delta^{(3)}(a(\mathbf{x} - \mathbf{x}')) = \frac{1}{|a|} \delta^{(3)}(\mathbf{x} - \mathbf{x}'). \quad (1.160)$$

In one dimension, this leads to the more general relation

$$\delta(f(x)) = \sum_i \frac{1}{|f'(x_i)|} \delta(x - x_i), \quad (1.161)$$

where x_i are the simple zeros of $f(x)$.

In mathematics, one calls the δ -function a *generalized function* or a *distribution*. It defines a linear functional of arbitrary smooth *test functions* $f(\mathbf{x})$ which yields its value at any desired place \mathbf{x} :

$$\delta[f; \mathbf{x}] \equiv \int d^3x \delta^{(3)}(\mathbf{x} - \mathbf{x}') f(\mathbf{x}') = f(\mathbf{x}). \quad (1.162)$$

Test functions are arbitrarily often differentiable functions with a sufficiently fast falloff at spatial infinity.

There exist a rich body of mathematical literature on distributions [3]. They form a linear space. This space is restricted in an essential way in comparison with ordinary functions: products of δ -functions or any other distributions remain undefined. In Section 10.8.1 we shall find, however, that physics forces us to go beyond these rules. An important requirement of quantum mechanics is coordinate invariance. If we want to achieve this for the path integral formulation of quantum mechanics, we must set up a definite extension of the existing theory of distributions, which specifies uniquely integrals over products of distributions.

In quantum mechanics, the role of the test functions is played by the wave packets $\Psi(\mathbf{x}, t)$. By admitting the generalized states $|\mathbf{x}\rangle$ to the Hilbert space, we also admit the scalar products $\langle \mathbf{x} | \mathbf{x}' \rangle$ to the space of wave functions, and thus all distributions, although they are not normalizable.

1.4.5 Schrödinger Equation in Dirac Notation

In terms of the bra-ket notation, the Schrödinger equation can be expressed in a basis-independent way as an operator equation

$$\hat{H}|\Psi(t)\rangle \equiv H(\hat{\mathbf{p}}, \hat{\mathbf{x}}, t)|\Psi(t)\rangle = i\hbar\partial_t|\Psi(t)\rangle, \quad (1.163)$$

to be supplemented by the following specifications of the canonical operators:

$$\langle \mathbf{x} | \hat{\mathbf{p}} \equiv -i\hbar \nabla \langle \mathbf{x} |, \quad (1.164)$$

$$\langle \mathbf{x} | \hat{\mathbf{x}} \equiv \mathbf{x} \langle \mathbf{x} |. \quad (1.165)$$

Any matrix element can be obtained from these equations by multiplication from the right with an arbitrary ket vector; for instance with the local basis vector $|\mathbf{x}'\rangle$:

$$\langle \mathbf{x} | \hat{\mathbf{p}} | \mathbf{x}' \rangle = -i\hbar \nabla \langle \mathbf{x} | \mathbf{x}' \rangle = -i\hbar \nabla \delta^{(3)}(\mathbf{x} - \mathbf{x}'), \quad (1.166)$$

$$\langle \mathbf{x} | \hat{\mathbf{x}} | \mathbf{x}' \rangle = \mathbf{x} \langle \mathbf{x} | \mathbf{x}' \rangle = \mathbf{x} \delta^{(3)}(\mathbf{x} - \mathbf{x}'). \quad (1.167)$$

The original differential form of the Schrödinger equation (1.91) follows by multiplying the basis-independent Schrödinger equation (1.163) with the bra vector $\langle \mathbf{x} |$ from the left:

$$\begin{aligned} \langle \mathbf{x} | H(\hat{\mathbf{p}}, \hat{\mathbf{x}}, t) | \Psi(t) \rangle &= H(-i\hbar \nabla, \mathbf{x}, t) \langle \mathbf{x} | \Psi(t) \rangle \\ &= i\hbar \partial_t \langle \mathbf{x} | \Psi(t) \rangle. \end{aligned} \quad (1.168)$$

Obviously, $\hat{\mathbf{p}}$ and $\hat{\mathbf{x}}$ are Hermitian matrices in any basis,

$$\langle a | \hat{\mathbf{p}} | a' \rangle = \langle a' | \hat{\mathbf{p}} | a \rangle^*, \quad (1.169)$$

$$\langle a | \hat{\mathbf{x}} | a' \rangle = \langle a' | \hat{\mathbf{x}} | a \rangle^*, \quad (1.170)$$

and so is the Hamiltonian

$$\langle a | \hat{H} | a' \rangle = \langle a' | \hat{H} | a \rangle^*, \quad (1.171)$$

as long as it has the form (1.101).

The most general basis-independent operator that can be constructed in the generalized Hilbert space spanned by the states $|\mathbf{x}\rangle$ is some function of $\hat{\mathbf{p}}, \hat{\mathbf{x}}, t$,

$$\hat{O}(t) \equiv O(\hat{\mathbf{p}}, \hat{\mathbf{x}}, t). \quad (1.172)$$

In general, such an operator is called Hermitian if all its matrix elements have this property. In the basis-independent Dirac notation, the definition (1.97) of a Hermitian-adjoint operator $\hat{O}^\dagger(t)$ implies the equality of the matrix elements

$$\langle a | \hat{O}^\dagger(t) | a' \rangle \equiv \langle a' | \hat{O}(t) | a \rangle^*. \quad (1.173)$$

Thus we can rephrase Eqs. (1.169)–(1.171) in the basis-independent form

$$\begin{aligned} \hat{\mathbf{p}} &= \hat{\mathbf{p}}^\dagger, \\ \hat{\mathbf{x}} &= \hat{\mathbf{x}}^\dagger, \\ \hat{H} &= \hat{H}^\dagger. \end{aligned} \quad (1.174)$$

The stationary states in Eq. (1.94) have a Dirac ket representation $|E_n\rangle$, and satisfy the time-independent operator equation

$$\hat{H} |E_n\rangle = E_n |E_n\rangle. \quad (1.175)$$

1.4.6 Momentum States

Let us now look at the momentum $\hat{\mathbf{p}}$. Its eigenstates are given by the eigenvalue equation

$$\hat{\mathbf{p}}|\mathbf{p}\rangle = \mathbf{p}|\mathbf{p}\rangle. \quad (1.176)$$

By multiplying this with $\langle \mathbf{x} |$ from the left and using (1.164), we find the differential equation

$$\langle \mathbf{x} | \hat{\mathbf{p}} | \mathbf{p} \rangle = -i\hbar \partial_{\mathbf{x}} \langle \mathbf{x} | \mathbf{p} \rangle = \mathbf{p} \langle \mathbf{x} | \mathbf{p} \rangle. \quad (1.177)$$

The solution is

$$\langle \mathbf{x} | \mathbf{p} \rangle \propto e^{i\mathbf{p}\mathbf{x}/\hbar}. \quad (1.178)$$

Up to a normalization factor, this is just a plane wave introduced before in Eq. (1.75) to describe free particles of momentum \mathbf{p} .

In order for the states $|\mathbf{p}\rangle$ to have a finite norm, the system must be confined to a finite volume, say a cubic box of length L and volume L^3 . Assuming periodic boundary conditions, the momenta are discrete with values

$$\mathbf{p}^{\mathbf{m}} = \frac{2\pi\hbar}{L}(m_1, m_2, m_3), \quad m_i = 0, \pm 1, \pm 2, \dots \quad (1.179)$$

Then we adjust the factor in front of $\exp(i\mathbf{p}^{\mathbf{m}}\mathbf{x}/\hbar)$ to achieve unit normalization

$$\langle \mathbf{x} | \mathbf{p}^{\mathbf{m}} \rangle = \frac{1}{\sqrt{L^3}} \exp(i\mathbf{p}^{\mathbf{m}}\mathbf{x}/\hbar), \quad (1.180)$$

and the discrete states $|\mathbf{p}^{\mathbf{m}}\rangle$ satisfy

$$\int d^3x |\langle \mathbf{x} | \mathbf{p}^{\mathbf{m}} \rangle|^2 = 1. \quad (1.181)$$

The states $|\mathbf{p}^{\mathbf{m}}\rangle$ are complete:

$$\sum_{\mathbf{m}} |\mathbf{p}^{\mathbf{m}}\rangle \langle \mathbf{p}^{\mathbf{m}}| = 1. \quad (1.182)$$

We may use this relation and the matrix elements $\langle \mathbf{x} | \mathbf{p}^{\mathbf{m}} \rangle$ to expand any wave function within the box as

$$\Psi(\mathbf{x}, t) = \langle \mathbf{x} | \Psi(t) \rangle = \sum_{\mathbf{m}} \langle \mathbf{x} | \mathbf{p}^{\mathbf{m}} \rangle \langle \mathbf{p}^{\mathbf{m}} | \Psi(t) \rangle. \quad (1.183)$$

If the box is very large, the sum over the discrete momenta $\mathbf{p}^{\mathbf{m}}$ can be approximated by an integral over the momentum space [4].

$$\sum_{\mathbf{m}} \approx \int \frac{d^3p L^3}{(2\pi\hbar)^3}. \quad (1.184)$$

In this limit, the states $|\mathbf{p}^{\mathbf{m}}\rangle$ may be used to define a continuum of basis vectors with an improper normalization

$$|\mathbf{p}\rangle \approx \sqrt{L^3} |\mathbf{p}^{\mathbf{m}}\rangle, \quad (1.185)$$

in the same way as $|\mathbf{x}_n\rangle$ was used in (1.150) to define $|\mathbf{x}\rangle \sim (1/\sqrt{\epsilon^3})|\mathbf{x}^n\rangle$. The momentum states $|\mathbf{p}\rangle$ satisfy the orthogonality relation

$$\langle \mathbf{p}|\mathbf{p}'\rangle = (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p} - \mathbf{p}'), \quad (1.186)$$

with $\delta^{(3)}(\mathbf{p} - \mathbf{p}')$ being again the Dirac δ -function. Their completeness relation reads

$$\int \frac{d^3p}{(2\pi\hbar)^3} |\mathbf{p}\rangle \langle \mathbf{p}| = 1, \quad (1.187)$$

such that the expansion (1.183) becomes

$$\Psi(\mathbf{x}, t) = \int \frac{d^3p}{(2\pi\hbar)^3} \langle \mathbf{x}|\mathbf{p}\rangle \langle \mathbf{p}|\Psi(t)\rangle, \quad (1.188)$$

with the momentum eigenfunctions

$$\langle \mathbf{x}|\mathbf{p}\rangle = e^{i\mathbf{p}\mathbf{x}/\hbar}. \quad (1.189)$$

This coincides precisely with the Fourier decomposition introduced above in the description of a general particle wave $\Psi(\mathbf{x}, t)$ in (1.83), (1.84), with the identification

$$\langle \mathbf{p}|\Psi(t)\rangle = f(\mathbf{p})e^{-iE_{\mathbf{p}}t/\hbar}. \quad (1.190)$$

The bra-ket formalism accommodates naturally the technique of Fourier transforms. The Fourier inversion formula is found by simply inserting into $\langle \mathbf{p}|\Psi(t)\rangle$ a completeness relation $\int d^3x |\mathbf{x}\rangle \langle \mathbf{x}| = 1$ which yields

$$\begin{aligned} \langle \mathbf{p}|\Psi(t)\rangle &= \int d^3x \langle \mathbf{p}|\mathbf{x}\rangle \langle \mathbf{x}|\Psi(t)\rangle \\ &= \int d^3x e^{-i\mathbf{p}\mathbf{x}/\hbar} \Psi(\mathbf{x}, t). \end{aligned} \quad (1.191)$$

The amplitudes $\langle \mathbf{p}|\Psi(t)\rangle$ are referred to as *momentum space wave functions*.

By inserting the completeness relation

$$\int d^3x |\mathbf{x}\rangle \langle \mathbf{x}| = 1 \quad (1.192)$$

between the momentum states on the left-hand side of the orthogonality relation (1.186), we obtain the Fourier representation of the δ -function (1.186):

$$\begin{aligned} \langle \mathbf{p}|\mathbf{p}'\rangle &= \int d^3x \langle \mathbf{p}|\mathbf{x}\rangle \langle \mathbf{x}|\mathbf{p}'\rangle \\ &= \int d^3x e^{-i(\mathbf{p}-\mathbf{p}')\mathbf{x}/\hbar} = (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p} - \mathbf{p}'). \end{aligned} \quad (1.193)$$

1.4.7 Incompleteness and Poisson's Summation Formula

For many physical applications it is important to find out what happens to the completeness relation (1.148) if one restricts the integral to a subset of positions. Most relevant will be the one-dimensional integral,

$$\int dx |x\rangle\langle x| = 1, \quad (1.194)$$

restricted to a sum over equally spaced points $x_n = na$:

$$\sum_{n=-N}^N |x_n\rangle\langle x_n|. \quad (1.195)$$

Taking this sum between momentum eigenstates $|p\rangle$, we obtain

$$\sum_{n=-N}^N \langle p|x_n\rangle\langle x_n|p'\rangle = \sum_{n=-N}^N \langle p|x_n\rangle\langle x_n|p'\rangle = \sum_{n=-N}^N e^{i(p-p')na/\hbar} \quad (1.196)$$

For $N \rightarrow \infty$ we can perform the sum with the help of *Poisson's summation formula*

$$\sum_{n=-\infty}^{\infty} e^{2\pi i \mu n} = \sum_{m=-\infty}^{\infty} \delta(\mu - m). \quad (1.197)$$

Identifying μ with $(p - p')a/2\pi\hbar$, we find using Eq. (1.160):

$$\sum_{n=-\infty}^{\infty} \langle p|x_n\rangle\langle x_n|p'\rangle = \sum_{m=-\infty}^{\infty} \delta\left(\frac{(p-p')a}{2\pi\hbar} - m\right) = \sum_{m=-\infty}^{\infty} \frac{2\pi\hbar}{a} \delta\left(p-p' - \frac{2\pi\hbar m}{a}\right). \quad (1.198)$$

In order to prove the Poisson formula (1.197), we observe that the sum $s(\mu) \equiv \sum_m \delta(\mu - m)$ on the right-hand side is periodic in μ with a unit period and has the Fourier series $s(\mu) = \sum_{n=-\infty}^{\infty} s_n e^{2\pi i \mu n}$. The Fourier coefficients are given by $s_n = \int_{-1/2}^{1/2} d\mu s(\mu) e^{-2\pi i \mu n} \equiv 1$. These are precisely the Fourier coefficients on the left-hand side.

For a finite N , the sum over n on the left-hand side of (1.197) yields

$$\begin{aligned} \sum_{n=-N}^N e^{2\pi i \mu n} &= 1 + \left(e^{2\pi i \mu} + e^{2 \cdot 2\pi i \mu} + \dots + e^{N \cdot 2\pi i \mu} + \text{c.c.} \right) \\ &= -1 + \left(\frac{1 - e^{2\pi i \mu(N+1)}}{1 - e^{2\pi i \mu}} + \text{c.c.} \right) \\ &= 1 + \frac{e^{2\pi i \mu} - e^{2\pi i \mu(N+1)}}{1 - e^{2\pi i \mu}} + \text{c.c.} = \frac{\sin \pi \mu(2N+1)}{\sin \pi \mu}. \end{aligned} \quad (1.199)$$

This function is well known in wave optics (see Fig. 2.4). It determines the diffraction pattern of light behind a grating with $2N + 1$ slits. It has large peaks at

Figure 1.2 Relevant function $\sum_{n=-N}^N e^{2\pi i \mu n}$ in Poisson's summation formula. In the limit $N \rightarrow \infty$, μ is squeezed to the integer values.

$\mu = 0, \pm 1, \pm 2, \pm 3, \dots$ and $N - 1$ small maxima between each pair of neighboring peaks, at $\nu = (1 + 4k)/2(2N + 1)$ for $k = 1, \dots, N - 1$. There are zeros at $\nu = (1 + 2k)/(2N + 1)$ for $k = 1, \dots, N - 1$.

Inserting $\mu = (p - p')a/2\pi\hbar$ into (1.199), we obtain

$$\sum_{n=-N}^N \langle p|x_n \rangle \langle x_n|p' \rangle = \frac{\sin(p - p')a(2N + 1)/2\hbar}{\sin(p - p')a/2\hbar}. \quad (1.200)$$

Let us see how the right-hand side of (1.199) turns into the right-hand side of (1.197) in the limit $N \rightarrow \infty$. In this limit, the area under each large peak can be calculated by an integral over the central large peak plus a number n of small maxima next to it:

$$\int_{-n/2N}^{n/2N} d\mu \frac{\sin \pi \mu (2N + 1)}{\sin \pi \mu} = \int_{-n/2N}^{n/2N} d\mu \frac{\sin 2\pi \mu N \cos \pi \mu + \cos 2\pi \mu N \sin \pi \mu}{\sin \pi \mu}. \quad (1.201)$$

Keeping a fixed ratio $n/N \ll 1$, we may replace in the integrand $\sin \pi \mu$ by $\pi \mu$ and $\cos \pi \mu$ by 1. Then the integral becomes, for $N \rightarrow \infty$ at fixed n/N ,

$$\begin{aligned} \int_{-n/2N}^{n/2N} d\mu \frac{\sin \pi \mu (2N + 1)}{\sin \pi \mu} &\xrightarrow{N \rightarrow \infty} \int_{-n/2N}^{n/2N} d\mu \frac{\sin 2\pi \mu N}{\pi \mu} + \int_{-n/2N}^{n/2N} d\mu \cos 2\pi \mu N \\ &\xrightarrow{N \rightarrow \infty} \frac{1}{\pi} \int_{-\pi n}^{\pi n} dx \frac{\sin x}{x} + \frac{1}{2\pi N} \int_{-\pi n}^{\pi n} dx \cos x \xrightarrow{N \rightarrow \infty} 1, \end{aligned} \quad (1.202)$$

where we have used the integral formula

$$\int_{-\infty}^{\infty} dx \frac{\sin x}{x} = \pi. \quad (1.203)$$

In the limit $N \rightarrow \infty$, we find indeed (1.197) and thus (1.205).

There exists another useful way of expressing Poisson's formula. Consider an arbitrary smooth function $f(\mu)$ which possesses a convergent sum

$$\sum_{m=-\infty}^{\infty} f(m). \quad (1.204)$$

Then Poisson's formula (1.197) implies that the sum can be rewritten as an integral and an auxiliary sum:

$$\sum_{m=-\infty}^{\infty} f(m) = \int_{-\infty}^{\infty} d\mu \sum_{n=-\infty}^{\infty} e^{2\pi i \mu n} f(\mu). \quad (1.205)$$

The auxiliary sum over n squeezes μ to the integer numbers.

1.5 Observables

Changes of basis vectors are an important tool in analyzing the physically observable content of a wave vector. Let $A = A(\mathbf{p}, \mathbf{x})$ be an arbitrary time-independent real function of the phase space variables \mathbf{p} and \mathbf{x} . Important examples for such an A are \mathbf{p} and \mathbf{x} themselves, the Hamiltonian $H(\mathbf{p}, \mathbf{x})$, and the angular momentum $\mathbf{L} = \mathbf{x} \times \mathbf{p}$. Quantum-mechanically, there will be an observable operator associated with each such quantity. It is obtained by simply replacing the variables \mathbf{p} and \mathbf{x} in A by the corresponding operators $\hat{\mathbf{p}}$ and $\hat{\mathbf{x}}$:

$$\hat{A} \equiv A(\hat{\mathbf{p}}, \hat{\mathbf{x}}). \quad (1.206)$$

This replacement rule is the extension of the correspondence principle for the Hamiltonian operator (1.92) to more general functions in phase space, converting them into observable operators. It must be assumed that the replacement leads to a unique Hermitian operator, i.e., that there is no ordering problem of the type discussed in context with the Hamiltonian (1.101).⁸ If there are ambiguities, the naive correspondence principle is insufficient to determine the observable operator. Then the correct ordering must be decided by comparison with experiment, unless it can be specified by means of simple geometric principles. This will be done for the Hamiltonian operator in Chapter 8.

Once an observable operator \hat{A} is Hermitian, it has the useful property that the set of all eigenvectors $|a\rangle$ obtained by solving the equation

$$\hat{A}|a\rangle = a|a\rangle \quad (1.207)$$

can be used as a basis to span the Hilbert space. Among the eigenvectors, there is always a choice of orthonormal vectors $|a\rangle$ fulfilling the completeness relation

$$\sum_a |a\rangle\langle a| = 1. \quad (1.208)$$

⁸Note that this is true for the angular momentum $\mathbf{L} = \mathbf{x} \times \mathbf{p}$.

The vectors $|a\rangle$ can be used to extract physical information concerning the observable A from arbitrary state vector $|\Psi(t)\rangle$. For this we expand this vector in the basis $|a\rangle$:

$$|\Psi(t)\rangle = \sum_a |a\rangle \langle a|\Psi(t)\rangle. \quad (1.209)$$

The components

$$\langle a|\Psi(t)\rangle \quad (1.210)$$

yield the probability amplitude for measuring the eigenvalue a for the observable quantity A .

The wave function $\Psi(\mathbf{x}, t)$ itself is an example of this interpretation. If we write it as

$$\Psi(\mathbf{x}, t) = \langle \mathbf{x}|\Psi(t)\rangle, \quad (1.211)$$

it gives the probability amplitude for measuring the eigenvalues \mathbf{x} of the position operator $\hat{\mathbf{x}}$, i.e., $|\Psi(\mathbf{x}, t)|^2$ is the probability density in \mathbf{x} -space.

The expectation value of the observable operator (1.206) in the state $|\Psi(t)\rangle$ is defined as the matrix element

$$\langle \Psi(t)|\hat{A}|\Psi(t)\rangle \equiv \int d^3x \langle \Psi(t)|\mathbf{x}\rangle A(-i\hbar\nabla, \mathbf{x}) \langle \mathbf{x}|\Psi(t)\rangle. \quad (1.212)$$

1.5.1 Uncertainty Relation

We have seen before [see the discussion after (1.83), (1.84)] that the amplitudes in real space and those in momentum space have widths inversely proportional to each other, due to the properties of Fourier analysis. If a wave packet is localized in real space with a width $\Delta\mathbf{x}$, its momentum space wave function has a width $\Delta\mathbf{p}$ given by

$$\Delta\mathbf{x} \Delta\mathbf{p} \sim \hbar. \quad (1.213)$$

From the Hilbert space point of view this uncertainty relation can be shown to be a consequence of the fact that the operators $\hat{\mathbf{x}}$ and $\hat{\mathbf{p}}$ do not commute with each other, but the components satisfy the canonical commutation rules

$$\begin{aligned} [\hat{p}_i, \hat{x}_j] &= -i\hbar\delta_{ij}, \\ [\hat{x}_i, \hat{x}_j] &= 0, \\ [\hat{p}_i, \hat{p}_j] &= 0. \end{aligned} \quad (1.214)$$

In general, if an observable operator \hat{A} is measured to have a sharp value a in one state, this state must be an eigenstate of \hat{A} with an eigenvalue a :

$$\hat{A}|a\rangle = a|a\rangle. \quad (1.215)$$

This follows from the expansion

$$|\Psi(t)\rangle = \sum_a |a\rangle \langle a|\Psi(t)\rangle, \quad (1.216)$$

in which $|\langle a|\Psi(t)\rangle|^2$ is the probability to measure an arbitrary eigenvalue a . If this probability is sharply focused at a specific value of a , the state necessarily coincides with $|a\rangle$.

Given the set of all eigenstates $|a\rangle$ of \hat{A} , we may ask under what circumstances another observable, say \hat{B} , can be measured sharply in each of these states. The requirement implies that the states $|a\rangle$ are also eigenstates of \hat{B} ,

$$\hat{B}|a\rangle = b_a|a\rangle, \quad (1.217)$$

with some a -dependent eigenvalue b_a . If this is true for all $|a\rangle$,

$$\hat{B}\hat{A}|a\rangle = b_a a|a\rangle = a b_a|a\rangle = \hat{A}\hat{B}|a\rangle, \quad (1.218)$$

the operators \hat{A} and \hat{B} necessarily commute:

$$[\hat{A}, \hat{B}] = 0. \quad (1.219)$$

Conversely, it can be shown that a vanishing commutator is also sufficient for two observable operators to be simultaneously diagonalizable and thus to allow for simultaneous sharp measurements.

1.5.2 Density Matrix and Wigner Function

An important object for calculating observable properties of a quantum-mechanical system is the quantum mechanical density operator associated with a pure state

$$\hat{\rho}(t) \equiv |\Psi(t)\rangle\langle\Psi(t)|, \quad (1.220)$$

and the associated density matrix associated with a pure state

$$\rho(\mathbf{x}_1, \mathbf{x}_2; t) = \langle\mathbf{x}_1|\Psi(t)\rangle\langle\Psi(t)|\mathbf{x}_2\rangle. \quad (1.221)$$

The expectation value of any function $f(\mathbf{x}, \hat{\mathbf{p}})$ can be calculated from the trace

$$\langle\Psi(t)|f(\mathbf{x}, \hat{\mathbf{p}})|\Psi(t)\rangle = \text{tr} [f(\mathbf{x}, \hat{\mathbf{p}})\hat{\rho}(t)] = \int d^3x \langle\Psi(t)|\mathbf{x}\rangle f(\mathbf{x}, -i\hbar\nabla) \langle\mathbf{x}|\Psi(t)\rangle. \quad (1.222)$$

If we decompose the states $|\Psi(t)\rangle$ into stationary eigenstates $|E_n\rangle$ of the Hamiltonian operator \hat{H} [recall (1.175)], $|\Psi(t)\rangle = \sum_n |E_n\rangle\langle E_n|\Psi(t)\rangle$, then the density matrix has the expansion

$$\hat{\rho}(t) \equiv \sum_{n,m} |E_n\rangle\rho_{nm}(t)\langle E_m| = \sum_{n,m} |E_n\rangle\langle E_n|\Psi(t)\rangle\langle\Psi(t)|E_m\rangle\langle E_m|. \quad (1.223)$$

Wigner showed that the Fourier transform of the density matrix, the *Wigner function*

$$W(\mathbf{X}, \mathbf{p}; t) \equiv \int \frac{d^3\Delta\mathbf{x}}{(2\pi\hbar)^3} e^{i\mathbf{p}\Delta\mathbf{x}/\hbar} \rho(\mathbf{X} + \Delta\mathbf{x}/2, \mathbf{X} - \Delta\mathbf{x}/2; t) \quad (1.224)$$

satisfies, for a single particle of mass M in a potential $V(\mathbf{x})$, the Wigner-Liouville equation

$$\left(\partial_t + \mathbf{v} \cdot \nabla_{\mathbf{x}}\right) W(\mathbf{X}, \mathbf{p}; t) = W_t(\mathbf{X}, \mathbf{p}; t), \quad \mathbf{v} \equiv \frac{\mathbf{p}}{M}, \quad (1.225)$$

where

$$W_t(\mathbf{X}, \mathbf{p}; t) \equiv \frac{2}{\hbar} \int \frac{d^3 q}{(2\pi\hbar)^3} W(\mathbf{X}, \mathbf{p} - \mathbf{q}; t) \int d^3 \Delta \mathbf{x} V(\mathbf{X} - \Delta \mathbf{x}/2) e^{i\mathbf{q}\Delta \mathbf{x}/\hbar}. \quad (1.226)$$

In the limit $\hbar \rightarrow 0$, we may expand $W(\mathbf{X}, \mathbf{p} - \mathbf{q}; t)$ in powers of \mathbf{q} , and $V(\mathbf{X} - \Delta \mathbf{x}/2)$ in powers of $\Delta \mathbf{x}$, which we rewrite in front of the exponential $e^{i\mathbf{q}\Delta \mathbf{x}/\hbar}$ as powers of $-i\hbar \nabla_{\mathbf{q}}$. Then we perform the integral over $\Delta \mathbf{x}$ to obtain $(2\pi\hbar)^3 \delta^{(3)}(\mathbf{q})$, and perform the integral over \mathbf{q} to obtain the classical *Liouville equation* for the probability density of the particle in phase space

$$\left(\partial_t + \mathbf{v} \cdot \nabla_{\mathbf{x}}\right) W(\mathbf{X}, \mathbf{p}; t) = -F(\mathbf{X}) \nabla_{\mathbf{p}} W(\mathbf{X}, \mathbf{p}; t), \quad \mathbf{v} \equiv \frac{\mathbf{p}}{M}, \quad (1.227)$$

where $F(\mathbf{X}) \equiv -\nabla_{\mathbf{x}} V(\mathbf{X})$ is the force associated with the potential $V(\mathbf{X})$.

1.5.3 Generalization to Many Particles

All this development can be extended to systems of N distinguishable mass points with Cartesian coordinates $\mathbf{x}_1, \dots, \mathbf{x}_N$. If $H(\mathbf{p}_\nu, \mathbf{x}_\nu, t)$ is the Hamiltonian, the Schrödinger equation becomes

$$H(\hat{\mathbf{p}}_\nu, \hat{\mathbf{x}}_\nu, t) |\Psi(t)\rangle = i\hbar \partial_t |\Psi(t)\rangle. \quad (1.228)$$

We may introduce a complete local basis $|\mathbf{x}_1, \dots, \mathbf{x}_N\rangle$ with the properties

$$\begin{aligned} \langle \mathbf{x}_1, \dots, \mathbf{x}_N | \mathbf{x}'_1, \dots, \mathbf{x}'_N \rangle &= \delta^{(3)}(\mathbf{x}_1 - \mathbf{x}'_1) \cdots \delta^{(3)}(\mathbf{x}_N - \mathbf{x}'_N), \\ \int d^3 x_1 \cdots d^3 x_N |\mathbf{x}_1, \dots, \mathbf{x}_N\rangle \langle \mathbf{x}_1, \dots, \mathbf{x}_N| &= 1, \end{aligned} \quad (1.229)$$

and define

$$\begin{aligned} \langle \mathbf{x}_1, \dots, \mathbf{x}_N | \hat{\mathbf{p}}_\nu &= -i\hbar \partial_{\mathbf{x}_\nu} \langle \mathbf{x}_1, \dots, \mathbf{x}_N |, \\ \langle \mathbf{x}_1, \dots, \mathbf{x}_N | \hat{\mathbf{x}}_\nu &= \mathbf{x}_\nu \langle \mathbf{x}_1, \dots, \mathbf{x}_N |. \end{aligned} \quad (1.230)$$

The Schrödinger equation for N particles (1.107) follows from (1.228) by multiplying it from the left with the bra vectors $\langle \mathbf{x}_1, \dots, \mathbf{x}_N |$. In the same way, all other formulas given above can be generalized to N -body state vectors.

1.6 Time Evolution Operator

If the Hamiltonian operator possesses no explicit time dependence, the basis-independent Schrödinger equation (1.163) can be integrated to find the wave function $|\Psi(t)\rangle$ at any time t_b from the state at any other time t_a

$$|\Psi(t_b)\rangle = e^{-i(t_b - t_a)\hat{H}/\hbar} |\Psi(t_a)\rangle. \quad (1.231)$$

The operator

$$\hat{U}(t_b, t_a) = e^{-i(t_b - t_a)\hat{H}/\hbar} \quad (1.232)$$

is called the *time evolution operator*. It satisfies the differential equation

$$i\hbar\partial_{t_b}\hat{U}(t_b, t_a) = \hat{H}\hat{U}(t_b, t_a). \quad (1.233)$$

Its inverse is obtained by interchanging the order of t_b and t_a :

$$\hat{U}^{-1}(t_b, t_a) \equiv e^{i(t_b - t_a)\hat{H}/\hbar} = \hat{U}(t_a, t_b). \quad (1.234)$$

As an exponential of i times a Hermitian operator, \hat{U} is a *unitary operator* satisfying

$$\hat{U}^\dagger = \hat{U}^{-1}. \quad (1.235)$$

Indeed,

$$\begin{aligned} \hat{U}^\dagger(t_b, t_a) &= e^{i(t_b - t_a)\hat{H}^\dagger/\hbar} \\ &= e^{i(t_b - t_a)\hat{H}/\hbar} = \hat{U}^{-1}(t_b, t_a). \end{aligned} \quad (1.236)$$

If $H(\hat{\mathbf{p}}, \hat{\mathbf{x}}, t)$ depends explicitly on time, the integration of the Schrödinger equation (1.163) is somewhat more involved. The solution may be found iteratively: For $t_b > t_a$, the time interval is sliced into a large number $N + 1$ of small pieces of thickness ϵ with $\epsilon \equiv (t_b - t_a)/(N + 1)$, slicing once at each time $t_n = t_a + n\epsilon$ for $n = 0, \dots, N + 1$. We then use the Schrödinger equation (1.163) to relate the wave function in each slice approximately to the previous one:

$$\begin{aligned} |\Psi(t_a + \epsilon)\rangle &\approx \left(1 - \frac{i}{\hbar} \int_{t_a}^{t_a + \epsilon} dt \hat{H}(t)\right) |\Psi(t_a)\rangle, \\ |\Psi(t_a + 2\epsilon)\rangle &\approx \left(1 - \frac{i}{\hbar} \int_{t_a + \epsilon}^{t_a + 2\epsilon} dt \hat{H}(t)\right) |\Psi(t_a + \epsilon)\rangle, \\ &\vdots \\ |\Psi(t_a + (N + 1)\epsilon)\rangle &\approx \left(1 - \frac{i}{\hbar} \int_{t_a + N\epsilon}^{t_a + (N + 1)\epsilon} dt \hat{H}(t)\right) |\Psi(t_a + N\epsilon)\rangle. \end{aligned} \quad (1.237)$$

From the combination of these equations we extract the evolution operator as a product

$$\hat{U}(t_b, t_a) \approx \left(1 - \frac{i}{\hbar} \int_{t_N}^{t_b} dt'_{N+1} \hat{H}(t'_{N+1})\right) \times \dots \times \left(1 - \frac{i}{\hbar} \int_{t_a}^{t_1} dt'_1 \hat{H}(t'_1)\right). \quad (1.238)$$

By multiplying out the product and going to the limit $N \rightarrow \infty$ we find the series

$$\begin{aligned} \hat{U}(t_b, t_a) &= 1 - \frac{i}{\hbar} \int_{t_a}^{t_b} dt'_1 \hat{H}(t'_1) + \left(\frac{-i}{\hbar}\right)^2 \int_{t_a}^{t_b} dt'_2 \int_{t_a}^{t'_2} dt'_1 \hat{H}(t'_2)\hat{H}(t'_1) \\ &\quad + \left(\frac{-i}{\hbar}\right)^3 \int_{t_a}^{t_b} dt'_3 \int_{t_a}^{t'_3} dt'_2 \int_{t_a}^{t'_2} dt'_1 \hat{H}(t'_3)\hat{H}(t'_2)\hat{H}(t'_1) + \dots, \end{aligned} \quad (1.239)$$

Figure 1.3 Illustration of time-ordering procedure in Eq. (1.243).

known as the *Neumann-Liouville expansion* or *Dyson series*. An interesting modification of this is the so-called *Magnus expansion* to be derived in Eq. (2A.25).

Note that each integral has the time arguments in the Hamilton operators ordered *causally*: Operators with later times stand to left of those with earlier times. It is useful to introduce a *time-ordering operator* which, when applied to an arbitrary product of operators,

$$\hat{O}_n(t_n) \cdots \hat{O}_1(t_1), \quad (1.240)$$

reorders the times successively. More explicitly we define

$$\hat{T}(\hat{O}_n(t_n) \cdots \hat{O}_1(t_1)) \equiv \hat{O}_{i_n}(t_{i_n}) \cdots \hat{O}_{i_1}(t_{i_1}), \quad (1.241)$$

where t_{i_n}, \dots, t_{i_1} are the times t_n, \dots, t_1 relabeled in the causal order, so that

$$t_{i_n} > t_{i_{n-1}} > \dots > t_{i_1}. \quad (1.242)$$

Any *c*-number factors in (1.241) can be pulled out in front of the \hat{T} operator. With this formal operator, the Neumann-Liouville expansion can be rewritten in a more compact way. Take, for instance, the third term in (1.239)

$$\int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_2} dt_1 \hat{H}(t_2) \hat{H}(t_1). \quad (1.243)$$

The integration covers the triangle above the diagonal in the square $t_1, t_2 \in [t_a, t_b]$ in the (t_1, t_2) plane (see Fig. 1.2). By comparing this with the missing integral over the lower triangle

$$\int_{t_a}^{t_b} dt_2 \int_{t_2}^{t_b} dt_1 \hat{H}(t_2) \hat{H}(t_1) \quad (1.244)$$

we see that the two expressions coincide except for the order of the operators. This can be corrected with the use of a time-ordering operator \hat{T} . The expression

$$\hat{T} \int_{t_a}^{t_b} dt_2 \int_{t_2}^{t_b} dt_1 \hat{H}(t_2) \hat{H}(t_1) \quad (1.245)$$

is equal to (1.243) since it may be rewritten as

$$\int_{t_a}^{t_b} dt_2 \int_{t_2}^{t_b} dt_1 \hat{H}(t_1) \hat{H}(t_2) \quad (1.246)$$

or, after interchanging the order of integration, as

$$\int_{t_a}^{t_b} dt_1 \int_{t_a}^{t_1} dt_2 \hat{H}(t_1) \hat{H}(t_2). \quad (1.247)$$

Apart from the dummy integration variables $t_2 \leftrightarrow t_1$, this double integral coincides with (1.243). Since the time arguments are properly ordered, (1.243) can trivially be multiplied with the time-ordering operator. The conclusion of this discussion is that (1.243) can alternatively be written as

$$\frac{1}{2} \hat{T} \int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_b} dt_1 \hat{H}(t_2) \hat{H}(t_1). \quad (1.248)$$

On the right-hand side, the integrations now run over the full square in the t_1, t_2 -plane so that the two integrals can be factorized into

$$\frac{1}{2} \hat{T} \left(\int_{t_a}^{t_b} dt \hat{H}(t) \right)^2. \quad (1.249)$$

Similarly, we may rewrite the n th-order term of (1.239) as

$$\begin{aligned} & \frac{1}{n!} \hat{T} \int_{t_a}^{t_b} dt_n \int_{t_a}^{t_b} dt_{n-1} \cdots \int_{t_a}^{t_b} dt_1 \hat{H}(t_n) \hat{H}(t_{n-1}) \cdots \hat{H}(t_1) \\ &= \frac{1}{n!} \hat{T} \left[\int_{t_a}^{t_b} dt \hat{H}(t) \right]^n. \end{aligned} \quad (1.250)$$

The time evolution operator $\hat{U}(t_b, t_a)$ has therefore the series expansion

$$\begin{aligned} \hat{U}(t_b, t_a) &= 1 - \frac{i}{\hbar} \hat{T} \int_{t_a}^{t_b} dt \hat{H}(t) + \frac{1}{2!} \left(\frac{-i}{\hbar} \right)^2 \hat{T} \left(\int_{t_a}^{t_b} dt \hat{H}(t) \right)^2 \\ &+ \dots + \frac{1}{n!} \left(\frac{-i}{\hbar} \right)^n \hat{T} \left(\int_{t_a}^{t_b} dt \hat{H}(t) \right)^n + \dots \end{aligned} \quad (1.251)$$

The right-hand side of \hat{T} contains simply the power series expansion of the exponential so that we can write

$$\hat{U}(t_b, t_a) = \hat{T} \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t_b} dt \hat{H}(t) \right\}. \quad (1.252)$$

If \hat{H} does not depend on the time, the time-ordering operation is superfluous, the integral can be done trivially, and we recover the previous result (1.232).

Note that a small variation $\delta \hat{H}(t)$ of $\hat{H}(t)$ changes $\hat{U}(t_b, t_a)$ by

$$\begin{aligned} \delta \hat{U}(t_b, t_a) &= -\frac{i}{\hbar} \int_{t_a}^{t_b} dt' \hat{T} \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t_b} dt \hat{H}(t) \right\} \delta \hat{H}(t') \hat{T} \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t'} dt \hat{H}(t) \right\} \\ &= -\frac{i}{\hbar} \int_{t_a}^{t_b} dt' \hat{U}(t_b, t') \delta \hat{H}(t') \hat{U}(t', t_a). \end{aligned} \quad (1.253)$$

A simple application for this relation is given in Appendix 1A.

1.7 Properties of the Time Evolution Operator

By construction, $\hat{U}(t_b, t_a)$ has some important properties:

a) Fundamental composition law

If two time translations are performed successively, the corresponding operators \hat{U} are related by

$$\hat{U}(t_b, t_a) = \hat{U}(t_b, t')\hat{U}(t', t_a), \quad t' \in (t_a, t_b). \quad (1.254)$$

This composition law makes the operators \hat{U} a representation of the abelian group of time translations. For time-independent Hamiltonians with $\hat{U}(t_b, t_a)$ given by (1.232), the proof of (1.254) is trivial. In the general case (1.252), it follows from the simple manipulation valid for $t_b > t_a$:

$$\begin{aligned} & \hat{T} \exp\left(-\frac{i}{\hbar} \int_{t'}^{t_b} \hat{H}(t) dt\right) \hat{T} \exp\left(-\frac{i}{\hbar} \int_{t_a}^{t'} \hat{H}(t) dt\right) \\ &= \hat{T} \left[\exp\left(-\frac{i}{\hbar} \int_{t'}^{t_b} \hat{H}(t) dt\right) \exp\left(-\frac{i}{\hbar} \int_{t_a}^{t'} \hat{H}(t) dt\right) \right] \\ &= \hat{T} \exp\left(-\frac{i}{\hbar} \int_{t_a}^{t_b} \hat{H}(t) dt\right). \end{aligned} \quad (1.255)$$

b) Unitarity

The expression (1.252) for the time evolution operator $\hat{U}(t_b, t_a)$ was derived only for the *causal* (or *retarded*) time arguments, i.e., for t_b later than t_a . We may, however, define $\hat{U}(t_b, t_a)$ also for the *anticausal* (or *advanced*) case where t_b lies before t_a . To be consistent with the above composition law (1.254), we must have

$$\hat{U}(t_b, t_a) \equiv \hat{U}(t_a, t_b)^{-1}. \quad (1.256)$$

Indeed, when considering two states at successive times

$$|\Psi(t_a)\rangle = \hat{U}(t_a, t_b)|\Psi(t_b)\rangle, \quad (1.257)$$

the order of succession is inverted by multiplying both sides by $\hat{U}^{-1}(t_a, t_b)$:

$$|\Psi(t_b)\rangle = \hat{U}(t_a, t_b)^{-1}|\Psi(t_a)\rangle, \quad t_b < t_a. \quad (1.258)$$

The operator on the right-hand side is defined to be the time evolution operator $\hat{U}(t_b, t_a)$ from the later time t_a to the earlier time t_b .

If the Hamiltonian is independent of time, with the time evolution operator being

$$\hat{U}(t_a, t_b) = e^{-i(t_a-t_b)\hat{H}/\hbar}, \quad t_a > t_b, \quad (1.259)$$

the unitarity of the operator $\hat{U}(t_b, t_a)$ is obvious:

$$\hat{U}^\dagger(t_b, t_a) = \hat{U}(t_b, t_a)^{-1}, \quad t_b < t_a. \quad (1.260)$$

Let us verify this property for a general time-dependent Hamiltonian. There, a direct solution of the Schrödinger equation (1.163) for the state vector shows that the operator $\hat{U}(t_b, t_a)$ for $t_b < t_a$ has a representation just like (1.252), except for a reversed time order of its arguments. One writes this in the form [compare (1.252)]

$$\hat{U}(t_b, t_a) = \hat{T} \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} \hat{H}(t) dt \right\}, \quad (1.261)$$

where \hat{T} denotes the time-antordering operator, with an obvious definition analogous to (1.241), (1.242). This operator satisfies the relation

$$\left[\hat{T} \left(\hat{O}_1(t_1) \hat{O}_2(t_2) \right) \right]^\dagger = \hat{T} \left(\hat{O}_2^\dagger(t_2) \hat{O}_1^\dagger(t_1) \right), \quad (1.262)$$

with an obvious generalization to the product of n operators. We can therefore conclude right away that

$$\hat{U}^\dagger(t_b, t_a) = \hat{U}(t_a, t_b), \quad t_b > t_a. \quad (1.263)$$

With $\hat{U}(t_a, t_b) \equiv \hat{U}(t_b, t_a)^{-1}$, this proves the unitarity relation (1.260), in general.

c) Schrödinger equation for $\hat{U}(t_b, t_a)$

Since the operator $\hat{U}(t_b, t_a)$ rules the relation between arbitrary wave functions at different times,

$$|\Psi(t_b)\rangle = \hat{U}(t_b, t_a) |\Psi(t_a)\rangle, \quad (1.264)$$

the Schrödinger equation (1.228) implies that the operator $\hat{U}(t_b, t_a)$ satisfies the corresponding equations

$$i\hbar \partial_t \hat{U}(t, t_a) = \hat{H} \hat{U}(t, t_a), \quad (1.265)$$

$$i\hbar \partial_t \hat{U}(t, t_a)^{-1} = -\hat{U}(t, t_a)^{-1} \hat{H}, \quad (1.266)$$

with the initial condition

$$\hat{U}(t_a, t_a) = 1. \quad (1.267)$$

1.8 Heisenberg Picture of Quantum Mechanics

The unitary time evolution operator $\hat{U}(t, t_a)$ may be used to give a different formulation of quantum mechanics bearing the closest resemblance to classical mechanics. This formulation, called the *Heisenberg picture* of quantum mechanics, is in a way more closely related to classical mechanics than the Schrödinger formulation. Many classical equations remain valid by simply replacing the canonical variables $p_i(t)$ and $q_i(t)$ in phase space by Heisenberg operators, to be denoted by $p_{Hi}(t)$, $q_{Hi}(t)$. Originally, Heisenberg postulated that they are matrices, but later it became clear that these matrices had to be functional matrix elements of operators, whose indices can be partly continuous. The classical equations hold for the Heisenberg operators

and as long as the canonical commutation rules (1.93) are respected at any given time. In addition, $q_i(t)$ must be Cartesian coordinates. In this case we shall always use the notation x_i for the position variable, as in Section 1.4, rather than q_i . The corresponding Heisenberg operators are $\hat{x}_{Hi}(t)$. Suppressing the subscripts i , the canonical equal-time commutation rules are

$$\begin{aligned} [\hat{p}_H(t), \hat{x}_H(t)] &= -i\hbar, \\ [\hat{p}_H(t), \hat{p}_H(t)] &= 0, \\ [\hat{x}_H(t), \hat{x}_H(t)] &= 0. \end{aligned} \tag{1.268}$$

According to Heisenberg, classical equations involving Poisson brackets remain valid if the Poisson brackets are replaced by i/\hbar times the matrix commutators at equal times. The canonical commutation relations (1.268) are a special case of this rule, recalling the fundamental Poisson brackets (1.24). The Hamilton equations of motion (1.23) turn into the Heisenberg equations

$$\begin{aligned} \frac{d}{dt}\hat{p}_H(t) &= \frac{i}{\hbar} [\hat{H}_H, \hat{p}_H(t)], \\ \frac{d}{dt}\hat{x}_H(t) &= \frac{i}{\hbar} [\hat{H}_H, \hat{x}_H(t)], \end{aligned} \tag{1.269}$$

where

$$\hat{H}_H \equiv H(\hat{p}_H(t), \hat{x}_H(t), t) \tag{1.270}$$

is the Hamiltonian in the Heisenberg picture. Similarly, the equation of motion for an arbitrary observable function $O(p_i(t), x_i(t), t)$ derived in (1.19) goes over into the matrix commutator equation for the Heisenberg operator

$$\hat{O}_H(t) \equiv O(\hat{p}_H(t), \hat{x}_H(t), t), \tag{1.271}$$

namely,

$$\frac{d}{dt}\hat{O}_H = \frac{i}{\hbar} [\hat{H}_H, \hat{O}_H] + \frac{\partial}{\partial t}\hat{O}_H. \tag{1.272}$$

These rules are referred to as *Heisenberg's correspondence principle*.

The relation between Schrödinger's and Heisenberg's picture is supplied by the time evolution operator. Let \hat{O} be an arbitrary observable in the Schrödinger description

$$\hat{O}(t) \equiv O(\hat{p}, \hat{x}, t). \tag{1.273}$$

If the states $|\Psi_a(t)\rangle$ are an arbitrary complete set of solutions of the Schrödinger equation, where a runs through discrete and continuous indices, the operator $\hat{O}(t)$ can be specified in terms of its functional matrix elements

$$O_{ab}(t) \equiv \langle \Psi_a(t) | \hat{O}(t) | \Psi_b(t) \rangle. \tag{1.274}$$

We can now use the unitary operator $\hat{U}(t, 0)$ to go to a new time-independent basis $|\Psi_{Ha}\rangle$, defined by

$$|\Psi_a(t)\rangle \equiv \hat{U}(t, 0) |\Psi_{Ha}\rangle. \tag{1.275}$$

Simultaneously, we transform the Schrödinger operators of the canonical coordinates \hat{p} and \hat{x} into the time-dependent canonical *Heisenberg operators* $\hat{p}_H(t)$ and $\hat{x}_H(t)$ via

$$\hat{p}_H(t) \equiv \hat{U}(t, 0)^{-1} \hat{p} \hat{U}(t, 0), \quad (1.276)$$

$$\hat{x}_H(t) \equiv \hat{U}(t, 0)^{-1} \hat{x} \hat{U}(t, 0). \quad (1.277)$$

At the time $t = 0$, the Heisenberg operators $\hat{p}_H(t)$ and $\hat{x}_H(t)$ coincide with the time-independent Schrödinger operators \hat{p} and \hat{x} , respectively. An arbitrary observable $\hat{O}(t)$ is transformed into the associated Heisenberg operator as

$$\begin{aligned} \hat{O}_H(t) &\equiv \hat{U}(t, t_a)^{-1} O(\hat{p}, \hat{x}, t) \hat{U}(t, t_a) \\ &\equiv O(\hat{p}_H(t), \hat{x}_H(t), t). \end{aligned} \quad (1.278)$$

The Heisenberg matrices $O_H(t)_{ab}$ are then obtained from the Heisenberg operators $\hat{O}_H(t)$ by sandwiching $\hat{O}_H(t)$ between the time-independent basis vectors $|\Psi_{Ha}\rangle$:

$$O_H(t)_{ab} \equiv \langle \Psi_{Ha} | \hat{O}_H(t) | \Psi_{Hb} \rangle. \quad (1.279)$$

Note that the time dependence of these matrix elements is now completely due to the time dependence of the operators,

$$\frac{d}{dt} O_H(t)_{ab} \equiv \langle \Psi_{Ha} | \frac{d}{dt} \hat{O}_H(t) | \Psi_{Hb} \rangle. \quad (1.280)$$

This is in contrast to the Schrödinger representation (1.274), where the right-hand side would have contained two more terms from the time dependence of the wave functions. Due to the absence of such terms in (1.280) it is possible to study the equation of motion of the Heisenberg matrices independently of the basis by considering directly the Heisenberg operators. It is straightforward to verify that they do indeed satisfy the rules of Heisenberg's correspondence principle. Consider the time derivative of an arbitrary observable $\hat{O}_H(t)$,

$$\begin{aligned} \frac{d}{dt} \hat{O}_H(t) &= \left(\frac{d}{dt} \hat{U}^{-1}(t, t_a) \right) \hat{O}(t) \hat{U}(t, t_a) \\ &+ \hat{U}^{-1}(t, t_a) \left(\frac{\partial}{\partial t} \hat{O}(t) \right) \hat{U}(t, t_a) + \hat{U}^{-1}(t, t_a) \hat{O}(t) \left(\frac{d}{dt} \hat{U}(t, t_a) \right), \end{aligned}$$

which can be rearranged as

$$\begin{aligned} &\left[\left(\frac{d}{dt} \hat{U}^{-1}(t, t_a) \right) \hat{U}(t, t_a) \right] \hat{U}^{-1}(t, t_a) \hat{O}(t) \hat{U}(t, t_a) \\ &+ \left[\hat{U}^{-1}(t, t_a) \hat{O}(t) \hat{U}(t, t_a) \right] \hat{U}^{-1}(t, t_a) \frac{d}{dt} \hat{U}(t, t_a) + \hat{U}^{-1}(t, t_a) \left(\frac{\partial}{\partial t} \hat{O}(t) \right) \hat{U}(t, t_a). \end{aligned} \quad (1.281)$$

Using (1.265), we obtain

$$\frac{d}{dt} \hat{O}_H(t) = \frac{i}{\hbar} \left[\hat{U}^{-1} \hat{H} \hat{U}, \hat{O}_H \right] + \hat{U}^{-1} \left(\frac{\partial}{\partial t} \hat{O}(t) \right) \hat{U}. \quad (1.282)$$

After inserting (1.278), we find the equation of motion for the Heisenberg operator:

$$\frac{d}{dt}\hat{O}_H(t) = \frac{i}{\hbar} [\hat{H}_H, \hat{O}_H(t)] + \left(\frac{\partial}{\partial t} \hat{O} \right)_H (t). \quad (1.283)$$

By sandwiching this equation between the complete time-independent basis states $|\Psi_a\rangle$ in the Hilbert space, it holds for the matrices and turns into the Heisenberg equation of motion. For the phase space variables $p_H(t)$, $x_H(t)$ themselves, these equations reduce, of course, to the Hamilton equations of motion (1.269).

Thus we have shown that Heisenberg's matrix quantum mechanics is completely equivalent to Schrödinger's quantum mechanics, and that the Heisenberg matrices obey the same Hamilton equations as the classical observables.

1.9 Interaction Picture and Perturbation Expansion

For some physical systems, the Hamiltonian operator can be split into two contributions

$$\hat{H} = \hat{H}_0 + \hat{V}, \quad (1.284)$$

where \hat{H}_0 is a so-called free Hamiltonian operator for which the Schrödinger equation $\hat{H}_0|\psi(t)\rangle = i\hbar\partial_t|\psi(t)\rangle$ can be solved, and \hat{V} is an interaction potential which perturbs these solutions slightly. In this case it is useful to describe the system in Dirac's *interaction picture*. We remove the time evolution of the unperturbed Schrödinger solutions and define the states

$$|\psi_I(t)\rangle \equiv e^{i\hat{H}_0 t/\hbar} |\psi(t)\rangle. \quad (1.285)$$

Their time evolution comes entirely from the interaction potential \hat{V} . It is governed by the time evolution operator

$$\hat{U}_I(t_b, t_a) \equiv e^{i\hat{H}_0 t_b/\hbar} e^{-iH(t_b-t_a)/\hbar} e^{-i\hat{H}_0 t_a/\hbar}, \quad (1.286)$$

and reads

$$|\psi_I(t_b)\rangle = \hat{U}_I(t_b, t_a) |\psi_I(t_a)\rangle. \quad (1.287)$$

If $\hat{V} = 0$, the states $|\psi_I(t_b)\rangle$ are time-independent and coincide with the Heisenberg states (1.275) of the operator \hat{H}_0 .

The operator $\hat{U}_I(t_b, t_a)$ satisfies the equation of motion

$$i\hbar\partial_{t_b}\hat{U}_I(t_b, t_a) = V_I(t_b)\hat{U}_I(t_b, t_a), \quad (1.288)$$

where

$$\hat{V}_I(t) \equiv e^{i\hat{H}_0 t/\hbar} \hat{V} e^{-i\hat{H}_0 t/\hbar} \quad (1.289)$$

is the potential in the interaction picture. This equation of motion can be turned into an integral equation

$$\hat{U}_I(t_b, t_a) = 1 - \frac{i}{\hbar} \int_{t_a}^{t_b} dt V_I(t) \hat{U}_I(t, t_a). \quad (1.290)$$

Inserting Eq. (1.289), this reads

$$\hat{U}_I(t_b, t_a) = 1 - \frac{i}{\hbar} \int_{t_a}^{t_b} dt e^{i\hat{H}_0 t/\hbar} V e^{-i\hat{H}_0 t/\hbar} \hat{U}_I(t, t_a). \quad (1.291)$$

This equation can be iterated to find a perturbation expansion for the operator $\hat{U}_I(t_b, t_a)$ in powers of the interaction potential:

$$\begin{aligned} \hat{U}_I(t_b, t_a) &= 1 - \frac{i}{\hbar} \int_{t_a}^{t_b} dt e^{i\hat{H}_0 t/\hbar} V e^{-i\hat{H}_0 t/\hbar} \\ &+ \left(-\frac{i}{\hbar}\right)^2 \int_{t_a}^{t_b} dt \int_{t_a}^t dt' e^{i\hat{H}_0 t/\hbar} V e^{-i\hat{H}_0(t-t')/\hbar} V e^{-i\hat{H}_0 t'/\hbar} + \dots \end{aligned} \quad (1.292)$$

Inserting on the left-hand side the operator (1.286) and multiplying the equation from the left by $e^{-i\hat{H}_0 t_b/\hbar}$ and from the right by $e^{i\hat{H}_0 t_a/\hbar}$, this can also be rewritten as

$$\begin{aligned} e^{-iH(t_b-t_a)/\hbar} &= e^{-iH_0(t_b-t_a)/\hbar} - \frac{i}{\hbar} \int_{t_a}^{t_b} dt e^{-i\hat{H}_0(t_b-t)/\hbar} V e^{-i\hat{H}_0(t-t_a)/\hbar} \\ &+ \left(-\frac{i}{\hbar}\right)^2 \int_{t_a}^{t_b} dt \int_{t_a}^t dt' e^{-i\hat{H}_0(t_b-t)/\hbar} V e^{-i\hat{H}_0(t-t')/\hbar} V e^{-i\hat{H}_0(t'-t_a)/\hbar} + \dots \end{aligned} \quad (1.293)$$

This expansion is seen to be the recursive solution of the integral equation

$$e^{-iH(t_b-t_a)/\hbar} = e^{-iH_0(t_b-t_a)/\hbar} - \frac{i}{\hbar} \int_{t_a}^{t_b} dt e^{-i\hat{H}_0(t_b-t)/\hbar} V e^{-i\hat{H}(t-t_a)/\hbar}. \quad (1.294)$$

Note that the lowest-order correction agrees with the previous formula (1.253)

Another way of writing the expansion (1.293) is

$$e^{-iH(t_b-t_a)/\hbar} = e^{-iH_0 t_b/\hbar} \hat{T} \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t_b} dt e^{i\hat{H}_0 t/\hbar} V e^{-i\hat{H}_0 t/\hbar} \right\} e^{iH t_a/\hbar}. \quad (1.295)$$

This may be recorded as a mathematical operator formula

$$e^{T(\hat{A}+\hat{B})} = \hat{T} e^{\int_0^T dt e^{(T-t)\hat{A}} \hat{B} e^{t\hat{A}}} = e^{T\hat{A}} \hat{T} e^{\int_0^T dt e^{-t\hat{A}} \hat{B} e^{t\hat{A}}}. \quad (1.296)$$

Due to the time-ordering operator, the right-hand side cannot be evaluated with the help *Lie's expansion formula*, also known as *Hadamard's lemma*

$$e^{-t\hat{A}} \hat{B} e^{t\hat{A}} = \hat{B} - t[\hat{A}, \hat{B}] + \frac{t^2}{2!} [\hat{A}, [\hat{A}, \hat{B}]] + \dots \quad (1.297)$$

Due to \hat{T} , the evaluation is considerably more involved and relegated to Appendix 2A. The proper expression of the right-hand side is referred to as the *Campbell-Baker-Hausdorff expansion*

A simple consequence of Hadamard's lemma is a variation formula for a time-dependent operator $\hat{A}(t)$:

$$\delta e^{\hat{A}(t)} = \int_0^1 dt e^{(1-t)\hat{A}} \delta \hat{A} e^{t\hat{A}}, \quad (1.298)$$

which follows from (1.297) by setting $\hat{B} = \delta \hat{A}$ and expanding $e^{T(\hat{A}+\delta\hat{A})} - e^{T\hat{A}}$ to lowest order in $\delta \hat{A}$. This is, of course, just another way of expressing Eq. (1.253).

1.10 Time Evolution Amplitude

In the subsequent development, an important role will be played by the matrix elements of the time evolution operator in the localized basis states,

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) \equiv \langle \mathbf{x}_b | \hat{U}(t_b, t_a) | \mathbf{x}_a \rangle. \quad (1.299)$$

They are referred to as *time evolution* amplitudes. The functional matrix $(\mathbf{x}_b t_b | \mathbf{x}_a t_a)$ is also called the *propagator* of the system. For a system with a time-independent Hamiltonian operator where $\hat{U}(t_b, t_a)$ is given by (1.259), the propagator is simply

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \langle \mathbf{x}_b | \exp[-i\hat{H}(t_b - t_a)/\hbar] | \mathbf{x}_a \rangle. \quad (1.300)$$

Due to the operator equations (1.265), the propagator satisfies the Schrödinger equation

$$[H(-i\hbar\partial_{\mathbf{x}_b}, \mathbf{x}_b, t_b) - i\hbar\partial_{t_b}] (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = 0. \quad (1.301)$$

In the quantum mechanics of nonrelativistic particles, only the propagators from earlier to later times will be relevant. It is therefore customary to introduce the so-called *causal time evolution operator* or *retarded time evolution operator*:⁹

$$\hat{U}^R(t_b, t_a) \equiv \begin{cases} \hat{U}(t_b, t_a), & t_b \geq t_a, \\ 0, & t_b < t_a, \end{cases} \quad (1.302)$$

and the associated *causal time evolution amplitude* or *retarded time evolution amplitude*

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a)^R \equiv \langle \mathbf{x}_b | \hat{U}^R(t_b, t_a) | \mathbf{x}_a \rangle. \quad (1.303)$$

Since this differs from (1.299) only for $t_b < t_a$, and since all formulas in the subsequent text will be used only for $t_b > t_a$, we shall often omit the superscript R . To abbreviate the case distinction in (1.302), it is convenient to use the *Heaviside function* defined by

$$\Theta(t) \equiv \begin{cases} 1 & \text{for } t > 0, \\ 0 & \text{for } t \leq 0, \end{cases} \quad (1.304)$$

and write

$$U^R(t_b, t_a) \equiv \Theta(t_b - t_a) \hat{U}(t_b, t_a), \quad (\mathbf{x}_b t_b | \mathbf{x}_a t_a)^R \equiv \Theta(t_b - t_a) (\mathbf{x}_b t_b | \mathbf{x}_a t_a). \quad (1.305)$$

There exists also another Heaviside function which differs from (1.304) only by the value at $t_b = t_a$:

$$\Theta^R(t) \equiv \begin{cases} 1 & \text{for } t \geq 0, \\ 0 & \text{for } t < 0. \end{cases} \quad (1.306)$$

Both Heaviside functions have the property that their derivative yields Dirac's δ -function

$$\partial_t \Theta(t) = \delta(t). \quad (1.307)$$

⁹Compare this with the retarded *Green functions* to be introduced in Section 18.1

If it is not important which Θ -function is used we shall ignore the superscript.

The retarded propagator satisfies the Schrödinger equation

$$\left[H(-i\hbar\partial_{\mathbf{x}_b}, \mathbf{x}_b, t_b)^R - i\hbar\partial_{t_b} \right] (\mathbf{x}_b t_b | \mathbf{x}_a t_a)^R = -i\hbar\delta(t_b - t_a)\delta^{(3)}(\mathbf{x}_b - \mathbf{x}_a). \quad (1.308)$$

The nonzero right-hand side arises from the extra term

$$-i\hbar [\partial_{t_b} \Theta(t_b - t_a)] (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = -i\hbar\delta(t_b - t_a) (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = -i\hbar\delta(t_b - t_a) (\mathbf{x}_b t_a | \mathbf{x}_a t_a) \quad (1.309)$$

and the initial condition $(\mathbf{x}_b t_a | \mathbf{x}_a t_a) = (\mathbf{x}_b | \mathbf{x}_a)$, due to (1.267).

If the Hamiltonian does not depend on time, the propagator depends only on the time difference $t = t_b - t_a$. The retarded propagator vanishes for $t < 0$. Functions $f(t)$ with this property have a characteristic Fourier transform. The integral

$$\tilde{f}(E) \equiv \int_0^\infty dt f(t) e^{iEt/\hbar} \quad (1.310)$$

is an analytic function in the upper half of the complex energy plane. This analyticity property is necessary and sufficient to produce a factor $\Theta(t)$ when inverting the Fourier transform via the energy integral

$$f(t) \equiv \int_{-\infty}^\infty \frac{dE}{2\pi\hbar} \tilde{f}(E) e^{-iEt/\hbar}. \quad (1.311)$$

For $t < 0$, the contour of integration may be closed by an infinite semicircle in the upper half-plane at no extra cost. Since the contour encloses no singularities, it can be contracted to a point, yielding $f(t) = 0$.

The Heaviside function $\Theta(t)$ itself is the simplest retarded function, with a Fourier representation containing just a single pole just below the origin of the complex energy plane:

$$\Theta(t) = \int_{-\infty}^\infty \frac{dE}{2\pi} \frac{i}{E + i\eta} e^{-iEt}, \quad (1.312)$$

where η is an infinitesimally small positive number. The integral representation is undefined for $t = 0$ and there are, in fact, infinitely many possible definitions for the Heaviside function depending on the value assigned to the function at the origin. A special role is played by the average of the Heaviside functions (1.306) and (1.304), which is equal to 1/2 at the origin:

$$\bar{\Theta}(t) \equiv \begin{cases} 1 & \text{for } t > 0, \\ \frac{1}{2} & \text{for } t = 0, \\ 0 & \text{for } t < 0. \end{cases} \quad (1.313)$$

Usually, the difference in the value at the origin does not matter since the Heaviside function appears only in integrals accompanied by some smooth function $f(t)$. This makes the Heaviside function a distribution with respect to smooth test functions $f(t)$ as defined in Eq. (1.162). All three distributions $\Theta_r(t)$, $\Theta^l(t)$, and $\bar{\Theta}(t)$ define the same linear functional of the test functions by the integral

$$\Theta[f] = \int dt \Theta(t - t') f(t'), \quad (1.314)$$

and this is an element in the linear space of all distributions.

As announced after Eq. (1.162), path integrals will specify, in addition, integrals over products of distribution and thus give rise to an important extension of the theory of distributions in Chapter 10. In this, the Heaviside function $\bar{\Theta}(t - t')$ plays the main role.

While discussing the concept of distributions let us introduce, for later use, the closely related distribution

$$\epsilon(t - t') \equiv \Theta(t - t') - \Theta(t' - t) = \bar{\Theta}(t - t') - \bar{\Theta}(t' - t), \quad (1.315)$$

which is a step function jumping at the origin from -1 to 1 as follows:

$$\epsilon(t - t') = \begin{cases} 1 & \text{for } t > t', \\ 0 & \text{for } t = t', \\ -1 & \text{for } t < t'. \end{cases} \quad (1.316)$$

1.11 Fixed-Energy Amplitude

The Fourier-transform of the retarded time evolution amplitude (1.303)

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \int_{-\infty}^{\infty} dt_b e^{iE(t_b - t_a)/\hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a)^R = \int_{t_a}^{\infty} dt_b e^{iE(t_b - t_a)/\hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) \quad (1.317)$$

is called the *fixed-energy amplitude*.

If the Hamiltonian does not depend on time, we insert here Eq. (1.300) and find that the fixed-energy amplitudes are matrix elements

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \langle \mathbf{x}_b | \hat{R}(E) | \mathbf{x}_a \rangle \quad (1.318)$$

of the so-called *resolvent operator*

$$\hat{R}(E) = \frac{i\hbar}{E - \hat{H} + i\eta}, \quad (1.319)$$

which is the Fourier transform of the retarded time evolution operator (1.302):

$$\hat{R}(E) = \int_{-\infty}^{\infty} dt_b e^{iE(t_b - t_a)/\hbar} \hat{U}^R(t_b, t_a) = \int_{t_a}^{\infty} dt_b e^{iE(t_b - t_a)/\hbar} \hat{U}(t_b, t_a). \quad (1.320)$$

Let us suppose that the time-independent Schrödinger equation is completely solved, i.e., that one knows all solutions $|\psi_n\rangle$ of the equation

$$\hat{H}|\psi_n\rangle = E_n|\psi_n\rangle. \quad (1.321)$$

These satisfy the completeness relation

$$\sum_n |\psi_n\rangle \langle \psi_n| = 1, \quad (1.322)$$

which can be inserted on the right-hand side of (1.300) between the Dirac brackets leading to the *spectral representation*

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \sum_n \psi_n(\mathbf{x}_b) \psi_n^*(\mathbf{x}_a) \exp[-iE_n(t_b - t_a)/\hbar], \quad (1.323)$$

with

$$\psi_n(\mathbf{x}) = \langle \mathbf{x} | \psi_n \rangle \quad (1.324)$$

being the wave functions associated with the eigenstates $|\psi_n\rangle$. Applying the Fourier transform (1.317), we obtain

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \sum_n \psi_n(\mathbf{x}_b) \psi_n^*(\mathbf{x}_a) R_n(E) = \sum_n \psi_n(\mathbf{x}_b) \psi_n^*(\mathbf{x}_a) \frac{i\hbar}{E - E_n + i\eta}. \quad (1.325)$$

The fixed-energy amplitude (1.317) contains as much information on the system as the time evolution amplitude, which is recovered from it by the inverse Fourier transformation

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \int_{-\infty}^{\infty} \frac{dE}{2\pi\hbar} e^{-iE(t_b - t_a)/\hbar} (\mathbf{x}_b | \mathbf{x}_a)_E. \quad (1.326)$$

The small $i\eta$ -shift in the energy E in (1.325) may be thought of as being attached to each of the energies E_n , which are thus placed by an infinitesimal piece *below* the real energy axis. Then the exponential behavior of the wave functions is slightly damped, going to zero at infinite time:

$$e^{-i(E_n - i\eta)t/\hbar} \rightarrow 0. \quad (1.327)$$

This so-called $i\eta$ -prescription ensures the causality of the Fourier representation (1.326). When doing the Fourier integral (1.326), the exponential $e^{iE(t_b - t_a)/\hbar}$ makes it always possible to close the integration contour along the energy axis by an infinite semicircle in the complex energy plane, which lies in the upper half-plane for $t_b < t_a$ and in the lower half-plane for $t_b > t_a$. The $i\eta$ -prescription guarantees that for $t_b < t_a$, there is no pole inside the closed contour making the propagator vanish. For $t_b > t_a$, on the other hand, the poles in the lower half-plane give, via Cauchy's residue theorem, the spectral representation (1.323) of the propagator. An $i\eta$ -prescription will appear in another context in Section 2.3.

If the eigenstates are nondegenerate, the residues at the poles of (1.325) render directly the products of eigenfunctions (barring degeneracies which must be discussed separately). For a system with a continuum of energy eigenvalues, there is a cut in the complex energy plane which may be thought of as a closely spaced sequence of poles. In general, the wave functions are recovered from the discontinuity of the amplitudes $(\mathbf{x}_b | \mathbf{x}_a)_E$ across the cut, using the formula

$$\text{disc} \left(\frac{i\hbar}{E - E_n} \right) \equiv \frac{i\hbar}{E - E_n + i\eta} - \frac{i\hbar}{E - E_n - i\eta} = 2\pi\hbar\delta(E - E_n). \quad (1.328)$$

Here we have employed the relation¹⁰, valid inside integrals over E :

$$\frac{1}{E - E_n \pm i\eta} = \frac{\mathcal{P}}{E - E_n} \mp i\pi\delta(E - E_n), \quad (1.329)$$

where \mathcal{P} indicates that the principal value of the integral has to be taken.

The energy integral over the discontinuity of the fixed-energy amplitude (1.325) $(\mathbf{x}_b|\mathbf{x}_a)_E$ reproduces the completeness relation (1.322) taken between the local states $\langle\mathbf{x}_b|$ and $|\mathbf{x}_a\rangle$,

$$\int_{-\infty}^{\infty} \frac{dE}{2\pi\hbar} \text{disc}(\mathbf{x}_b|\mathbf{x}_a)_E = \sum_n \psi_n(\mathbf{x}_b)\psi_n^*(\mathbf{x}_a) = \langle\mathbf{x}_b|\mathbf{x}_a\rangle = \delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a). \quad (1.330)$$

The completeness relation reflects the following property of the resolvent operator:

$$\int_{-\infty}^{\infty} \frac{dE}{2\pi\hbar} \text{disc} \hat{R}(E) = \hat{1}. \quad (1.331)$$

In general, the system possesses also a continuous spectrum, in which case the completeness relation contains a spectral integral and (1.322) has the form

$$\sum_n |\psi_n\rangle\langle\psi_n| + \int d\nu |\psi_\nu\rangle\langle\psi_\nu| = 1. \quad (1.332)$$

The continuum causes a branch cut along in the complex energy plane, and (1.330) includes an integral over the discontinuity along the cut. The cut will mostly be omitted, for brevity.

1.12 Free-Particle Amplitudes

For a free particle with a Hamiltonian operator $\hat{H} = \hat{\mathbf{p}}^2/2M$, the spectrum is continuous. The eigenfunctions are (1.189) with energies $E(\mathbf{p}) = \mathbf{p}^2/2M$. Inserting the completeness relation (1.187) into Eq. (1.300), we obtain for the time evolution amplitude of a free particle the Fourier representation

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \int \frac{d^D p}{(2\pi\hbar)^D} \exp \left\{ \frac{i}{\hbar} \left[\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a) - \frac{\mathbf{p}^2}{2M}(t_b - t_a) \right] \right\}. \quad (1.333)$$

The momentum integrals can easily be done. First we perform a quadratic completion in the exponent and rewrite it as

$$\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a) - \frac{1}{2M}\mathbf{p}^2(t_b - t_a) = \frac{1}{2M} \left(\mathbf{p} - \frac{1}{M} \frac{\mathbf{x}_b - \mathbf{x}_a}{t_b - t_a} \right)^2 (t_b - t_a) - \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a}. \quad (1.334)$$

¹⁰This is often referred to as *Sochocki's formula*. It is the beginning of an expansion in powers of $\eta > 0$: $1/(x \pm i\eta) = \mathcal{P}/x \mp i\pi\delta(x) + \eta[\pi\delta'(x) \pm id_x\mathcal{P}/x] + \mathcal{O}(\eta^2)$.

Then we replace the integration variables by the shifted momenta $\mathbf{p}' = \mathbf{p} - (\mathbf{x}_b - \mathbf{x}_a)/(t_b - t_a)M$, and the amplitude (1.333) becomes

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = F(t_b - t_a) \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} \right], \quad (1.335)$$

where $F(t_b - t_a)$ is the integral over the shifted momenta

$$F(t_b - t_a) \equiv \int \frac{d^D p'}{(2\pi\hbar)^D} \exp \left\{ -\frac{i}{\hbar} \frac{\mathbf{p}'^2}{2M} (t_b - t_a) \right\}. \quad (1.336)$$

This can be performed using the *Fresnel integral formula*

$$\int_{-\infty}^{\infty} \frac{dp}{\sqrt{2\pi}} \exp \left(i \frac{a}{2} p^2 \right) = \frac{1}{\sqrt{|a|}} \begin{cases} \sqrt{i}, & a > 0, \\ 1/\sqrt{i}, & a < 0. \end{cases} \quad (1.337)$$

Here the square root \sqrt{i} denotes the phase factor $e^{i\pi/4}$: This follows from the Gauss formula

$$\int_{-\infty}^{\infty} \frac{dp}{\sqrt{2\pi}} \exp \left(-\frac{\alpha}{2} p^2 \right) = \frac{1}{\sqrt{\alpha}}, \quad \text{Re } \alpha > 0, \quad (1.338)$$

by continuing α analytically from positive values into the right complex half-plane. As long as $\text{Re } \alpha > 0$, this is straightforward. On the boundaries, i.e., on the positive and negative imaginary axes, one has to be careful. At $\alpha = \pm ia + \eta$ with $a \gtrless 0$ and infinitesimal $\eta > 0$, the integral is certainly convergent yielding (1.337). But the integral also converges for $\eta = 0$, as can easily be seen by substituting $x^2 = z$. See Appendix 1B.

Note that differentiation of Eq. (1.338) with respect to α yields the more general Gaussian integral formula

$$\int_{-\infty}^{\infty} \frac{dp}{\sqrt{2\pi}} p^{2n} \exp \left(-\frac{\alpha}{2} p^2 \right) = \frac{1}{\sqrt{\alpha}} \frac{(2n-1)!!}{\alpha^n} \quad \text{Re } \alpha > 0, \quad (1.339)$$

where $(2n-1)!!$ is defined as the product $(2n-1) \cdot (2n-3) \cdots 1$. For odd powers p^{2n+1} , the integral vanishes. In the Fresnel formula (1.337), an extra integrand p^{2n} produces a factor $(i/a)^n$.

Since the Fresnel formula is a special analytically continued case of the Gauss formula, we shall in the sequel always speak of Gaussian integrations and use Fresnel's name only if the imaginary nature of the quadratic exponent is to be emphasized.

Applying this formula to (1.336), we obtain

$$F(t_b - t_a) = \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}}, \quad (1.340)$$

so that the full time evolution amplitude of a free massive point particle is

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} \right]. \quad (1.341)$$

In the limit $t_b \rightarrow t_a$, the left-hand side becomes the scalar product $\langle \mathbf{x}_b | \mathbf{x}_a \rangle = \delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a)$, implying the following limiting formula for the δ -function

$$\delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a) = \lim_{t_b - t_a \rightarrow 0} \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}^D} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} \right]. \quad (1.342)$$

Inserting Eq. (1.333) into (1.317), we have for the fixed-energy amplitude the integral representation

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \int_0^\infty d(t_b - t_a) \int \frac{d^D p}{(2\pi \hbar)^D} \exp \left\{ \frac{i}{\hbar} \left[\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a) + (t_b - t_a) \left(E - \frac{\mathbf{p}^2}{2M} \right) \right] \right\}. \quad (1.343)$$

Performing the time integration yields

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \int \frac{d^D p}{(2\pi \hbar)^D} \exp [i \mathbf{p}(\mathbf{x}_b - \mathbf{x}_a)] \frac{i \hbar}{E - \mathbf{p}^2 / 2M + i\eta}, \quad (1.344)$$

where we have inserted a damping factor $e^{-\eta(t_b - t_a)}$ into the integral to ensure convergence at large $t_b - t_a$. For a more explicit result it is more convenient to calculate the Fourier transform (1.341):

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \int_0^\infty d(t_b - t_a) \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}^D} \exp \left\{ \frac{i}{\hbar} \left[E(t_b - t_a) + \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} \right] \right\}. \quad (1.345)$$

For $E < 0$, we set

$$\kappa \equiv \sqrt{-2ME / \hbar^2}, \quad (1.346)$$

and perform the integral with the help of the formula¹¹

$$\int_0^\infty dt t^{\nu-1} e^{-i\gamma t + i\beta/t} = 2 \left(\frac{\beta}{\gamma} \right)^{\nu/2} e^{-i\nu\pi/2} K_{-\nu}(2\sqrt{\beta\gamma}), \quad (1.347)$$

where $K_\nu(z)$ is the modified Bessel function which satisfies $K_\nu(z) = K_{-\nu}(z)$ ¹² The result is

$$(\mathbf{x}_b | \mathbf{x}_a)_E = -i \frac{2M}{\hbar} \frac{\kappa^{D-2}}{(2\pi)^{D/2}} \frac{K_{D/2-1}(\kappa R)}{(\kappa R)^{D/2-1}}, \quad (1.348)$$

where $R \equiv |\mathbf{x}_b - \mathbf{x}_a|$. The simplest modified Bessel function is¹³

$$K_{1/2}(z) = K_{-1/2}(z) = \sqrt{\frac{\pi}{2z}} e^{-z}, \quad (1.349)$$

¹¹I.S. Gradshteyn and I.M. Ryzhik, *Table of Integrals, Series, and Products*, Academic Press, New York, 1980, Formulas 3.471.10, 3.471.11, and 8.432.6

¹²*ibid.*, Formula 8.486.16

so that we find for $D = 1, 2, 3$, the amplitudes

$$-i\frac{M}{\hbar}\frac{1}{\kappa}e^{-\kappa R}, \quad -i\frac{M}{\hbar}\frac{1}{\pi}K_0(\kappa R), \quad -i\frac{M}{\hbar}\frac{1}{2\pi R}e^{-\kappa R}. \quad (1.350)$$

At $R = 0$, the amplitude (1.348) is finite for all $D \leq 2$, where we can use the small-argument behavior of the associated Bessel function¹⁴

$$K_\nu(z) = K_{-\nu}(z) \approx \frac{1}{2}\Gamma(\nu)\left(\frac{z}{2}\right)^{-\nu} \quad \text{for } \text{Re } \nu > 0, \quad (1.351)$$

to obtain

$$(\mathbf{x}|\mathbf{x})_E = -i\frac{2M}{\hbar}\frac{\kappa^{D-2}}{(4\pi)^{D/2}}\Gamma(1 - D/2). \quad (1.352)$$

This result can be continued analytically to $D > 2$, which will be needed later (for example in Subsection 4.9.4).

For $E > 0$ we set

$$k \equiv \sqrt{2ME/\hbar^2} \quad (1.353)$$

and use the formula¹⁵

$$\int_0^\infty dt t^{\nu-1} e^{i\gamma t + i\beta/t} = i\pi \left(\frac{\beta}{\gamma}\right)^{\nu/2} e^{-i\nu\pi/2} H_{-\nu}^{(1)}(2\sqrt{\beta\gamma}), \quad (1.354)$$

where $H_\nu^{(1)}(z)$ is the Hankel function, to find

$$(\mathbf{x}_b|\mathbf{x}_a)_E = \frac{M\pi}{\hbar} \frac{k^{D-2}}{(2\pi)^{D/2}} \frac{H_{D/2-1}^{(1)}(kR)}{(kR)^{D/2-1}}. \quad (1.355)$$

The relation¹⁶

$$K_\nu(-iz) = \frac{\pi}{2} i e^{i\nu\pi/2} H_\nu^{(1)}(z) \quad (1.356)$$

connects the two formulas with each other when continuing the energy from negative to positive values, which replaces κ by $e^{-i\pi/2}k = -ik$.

For large distances, the asymptotic behavior¹⁷

$$K_\nu(z) \approx \sqrt{\frac{\pi}{2z}} e^{-z}, \quad H_\nu^{(1)}(z) \approx \sqrt{\frac{2}{\pi z}} e^{i(z - \nu\pi/2 - \pi/4)} \quad (1.357)$$

shows that the fixed-energy amplitude behaves for $E < 0$ like

$$(\mathbf{x}_b|\mathbf{x}_a)_E \approx -i\frac{M}{\hbar}\kappa^{D-2} \frac{1}{(2\pi)^{(D-1)/2}} \frac{1}{(\kappa R)^{(D-1)/2}} e^{-\kappa R/\hbar}, \quad (1.358)$$

and for $E > 0$ like

$$(\mathbf{x}_b|\mathbf{x}_a)_E \approx \frac{M}{\hbar} k^{D-2} \frac{1}{(2\pi i)^{(D-1)/2}} \frac{1}{(kR)^{(D-1)/2}} e^{ikR/\hbar}. \quad (1.359)$$

For $D = 1$ and 3 , these asymptotic expressions hold for all R .

1.13 Quantum Mechanics of General Lagrangian Systems

An extension of the quantum-mechanical formalism to systems described by a set of completely general Lagrange coordinates q_1, \dots, q_N is not straightforward. Only in the special case of q_i ($i = 1, \dots, N$) being merely a curvilinear reparametrization of a D -dimensional Euclidean space are the above correspondence rules sufficient to quantize the system. Then $N = D$ and a variable change from x^i to q_j in the Schrödinger equation leads to the correct quantum mechanics. It will be useful to label the curvilinear coordinates by Greek superscripts and write q^μ instead of q_j . This will help when we write all ensuing equations in a form that is manifestly covariant under coordinate transformations. In the original definition of generalized coordinates in Eq. (1.1), this was unnecessary since transformation properties were ignored. For the Cartesian coordinates we shall use Latin indices alternatively as sub- or superscripts. The coordinate transformation $x^i = x^i(q^\mu)$ implies the relation between the derivatives $\partial_\mu \equiv \partial/\partial q^\mu$ and $\partial_i \equiv \partial/\partial x^i$:

$$\partial_\mu = e^i{}_\mu(q)\partial_i, \quad (1.360)$$

with the transformation matrix

$$e^i{}_\mu(q) \equiv \partial_\mu x^i(q) \quad (1.361)$$

called *basis D-ad* (in 3 dimensions triad, in 4 dimensions tetrad, etc.). Let $e_i{}^\mu(q) = \partial q^\mu/\partial x^i$ be the inverse matrix (assuming it exists) called the *reciprocal D-ad*, satisfying with $e^i{}_\mu$ the orthogonality and completeness relations

$$e^i{}_\mu e_i{}^\nu = \delta_\mu{}^\nu, \quad e^i{}_\mu e_j{}^\mu = \delta^i{}_j. \quad (1.362)$$

Then, (1.360) is inverted to

$$\partial_i = e_i{}^\mu(q)\partial_\mu \quad (1.363)$$

and yields the curvilinear transform of the Cartesian quantum-mechanical momentum operators

$$\hat{p}_i = -i\hbar\partial_i = -i\hbar e_i{}^\mu(q)\partial_\mu. \quad (1.364)$$

The free-particle Hamiltonian operator

$$\hat{H}_0 = \hat{T} = \frac{1}{2M}\hat{\mathbf{p}}^2 = -\frac{\hbar^2}{2M}\nabla^2 \quad (1.365)$$

goes over into

$$\hat{H}_0 = -\frac{\hbar^2}{2M}\Delta, \quad (1.366)$$

where Δ is the Laplacian expressed in curvilinear coordinates:

$$\begin{aligned} \Delta &= \partial_i^2 = e^{i\mu}\partial_\mu e_i{}^\nu\partial_\nu \\ &= e^{i\mu}e_i{}^\nu\partial_\mu\partial_\nu + (e^{i\mu}\partial_\mu e_i{}^\nu)\partial_\nu. \end{aligned} \quad (1.367)$$

At this point one introduces the *metric tensor*

$$g_{\mu\nu}(q) \equiv e_{i\mu}(q)e^i{}_{\nu}(q), \quad (1.368)$$

its inverse

$$g^{\mu\nu}(q) = e^{i\mu}(q)e_i{}^{\nu}(q), \quad (1.369)$$

defined by $g^{\mu\nu}g_{\nu\lambda} = \delta^{\mu}{}_{\lambda}$, and the so-called *affine connection*

$$\Gamma_{\mu\nu}{}^{\lambda}(q) = -e^i{}_{\nu}(q)\partial_{\mu}e_i{}^{\lambda}(q) = e_i{}^{\lambda}(q)\partial_{\mu}e^i{}_{\nu}(q). \quad (1.370)$$

Then the Laplacian takes the form

$$\Delta = g^{\mu\nu}(q)\partial_{\mu}\partial_{\nu} - \Gamma_{\mu}{}^{\mu\nu}(q)\partial_{\nu}, \quad (1.371)$$

with $\Gamma_{\mu}{}^{\lambda\nu}$ being defined as the *contraction*

$$\Gamma_{\mu}{}^{\lambda\nu} \equiv g^{\lambda\kappa}\Gamma_{\mu\kappa}{}^{\nu}. \quad (1.372)$$

The reason why (1.368) is called a metric tensor is obvious: An infinitesimal square distance between two points in the original Cartesian coordinates

$$ds^2 \equiv d\mathbf{x}^2 \quad (1.373)$$

becomes in curvilinear coordinates

$$ds^2 = \frac{\partial\mathbf{x}}{\partial q^{\mu}} \frac{\partial\mathbf{x}}{\partial q^{\nu}} dq^{\mu} dq^{\nu} = g_{\mu\nu}(q) dq^{\mu} dq^{\nu}. \quad (1.374)$$

The infinitesimal volume element $d^D x$ is given by

$$d^D x = \sqrt{g} d^D q, \quad (1.375)$$

where

$$g(q) \equiv \det(g_{\mu\nu}(q)) \quad (1.376)$$

is the determinant of the metric tensor. Using this determinant, we form the quantity

$$\Gamma_{\mu} \equiv g^{-1/2}(\partial_{\mu}g^{1/2}) = \frac{1}{2}g^{\lambda\kappa}(\partial_{\mu}g_{\lambda\kappa}) \quad (1.377)$$

and see that it is equal to the once-contracted connection

$$\Gamma_{\mu} = \Gamma_{\mu\lambda}{}^{\lambda}. \quad (1.378)$$

With the inverse metric (1.369) we have furthermore

$$\Gamma_{\mu}{}^{\mu\nu} = -\partial_{\mu}g^{\mu\nu} - \Gamma_{\mu}{}^{\nu\mu}. \quad (1.379)$$

We now take advantage of the fact that the derivatives $\partial_\mu, \partial_\nu$ applied to the coordinate transformation $x^i(q)$ commute causing $\Gamma_{\mu\nu}^\lambda$ to be symmetric in $\mu\nu$, i.e., $\Gamma_{\mu\nu}^\lambda = \Gamma_{\nu\mu}^\lambda$ and hence $\Gamma_\mu^{\nu\mu} = \Gamma^\nu$. Together with (1.377) we find the rotation

$$\Gamma_\mu^{\mu\nu} = -\frac{1}{\sqrt{g}}(\partial_\mu g^{\mu\nu} \sqrt{g}), \quad (1.380)$$

which allows the Laplace operator Δ to be rewritten in the more compact form

$$\Delta = \frac{1}{\sqrt{g}} \partial_\mu g^{\mu\nu} \sqrt{g} \partial_\nu. \quad (1.381)$$

This expression is called the *Laplace-Beltrami operator*.¹⁸

Thus we have shown that for a Hamiltonian in a Euclidean space

$$H(\hat{\mathbf{p}}, \mathbf{x}) = \frac{1}{2M} \hat{\mathbf{p}}^2 + V(\mathbf{x}), \quad (1.382)$$

the Schrödinger equation in curvilinear coordinates becomes

$$\hat{H}\psi(q, t) \equiv \left[-\frac{\hbar^2}{2M} \Delta + V(q) \right] \psi(q, t) = i\hbar \partial_t \psi(q, t), \quad (1.383)$$

where $V(q)$ is short for $V(\mathbf{x}(q))$. The scalar product of two wave functions $\int d^D x \psi_2^*(\mathbf{x}, t) \psi_1(\mathbf{x}, t)$, which determines the transition amplitudes of the system, transforms into

$$\int d^D q \sqrt{g} \psi_2^*(q, t) \psi_1(q, t). \quad (1.384)$$

It is important to realize that this Schrödinger equation would *not* be obtained by a straightforward application of the canonical formalism to the coordinate-transformed version of the Cartesian Lagrangian

$$L(\mathbf{x}, \dot{\mathbf{x}}) = \frac{M}{2} \dot{\mathbf{x}}^2 - V(\mathbf{x}). \quad (1.385)$$

With the velocities transforming as

$$\dot{x}^i = e^i_\mu(q) \dot{q}^\mu, \quad (1.386)$$

the Lagrangian becomes

$$L(q, \dot{q}) = \frac{M}{2} g_{\mu\nu}(q) \dot{q}^\mu \dot{q}^\nu - V(q). \quad (1.387)$$

Up to a factor M , the metric is equal to the Hessian metric of the system, which depends here only on q^μ [recall (1.12)]:

$$H_{\mu\nu}(q) = M g_{\mu\nu}(q). \quad (1.388)$$

¹⁸More details will be given later in Eqs. (11.12)–(11.18).

The canonical momenta are

$$p_\mu \equiv \frac{\partial L}{\partial \dot{q}^\mu} = M g_{\mu\nu} \dot{q}^\nu. \quad (1.389)$$

The associated quantum-mechanical momentum operators \hat{p}_μ have to be Hermitian in the scalar product (1.384) and must satisfy the canonical commutation rules (1.268):

$$\begin{aligned} [\hat{p}_\mu, \hat{q}^\nu] &= -i\hbar \delta_\mu^\nu, \\ [\hat{q}^\mu, \hat{q}^\nu] &= 0, \\ [\hat{p}_\mu, \hat{p}_\nu] &= 0. \end{aligned} \quad (1.390)$$

An obvious solution is

$$\hat{p}_\mu = -i\hbar g^{-1/4} \partial_\mu g^{1/4}, \quad \hat{q}^\mu = q^\mu. \quad (1.391)$$

The commutation rules are true for $-i\hbar g^{-z} \partial_\mu g^z$ with any power z , but only $z = 1/4$ produces a Hermitian momentum operator:

$$\begin{aligned} \int d^3q \sqrt{g} \Psi_2^*(q, t) [-i\hbar g^{-1/4} \partial_\mu g^{1/4} \Psi_1(q, t)] &= \int d^3q g^{1/4} \Psi_2^*(q, t) [-i\hbar \partial_\mu g^{1/4} \Psi_1(q, t)] \\ &= \int d^3q \sqrt{g} [-i\hbar g^{-1/4} \partial_\mu g^{1/4} \Psi_2(q, t)]^* \Psi_1(q, t), \end{aligned} \quad (1.392)$$

as is easily verified by partial integration.

In terms of the quantity (1.377), this can also be rewritten as

$$\hat{p}_\mu = -i\hbar (\partial_\mu + \frac{1}{2} \Gamma_\mu). \quad (1.393)$$

Consider now the classical Hamiltonian associated with the Lagrangian (1.387), which by (1.389) is simply

$$H = p_\mu \dot{q}^\mu - L = \frac{1}{2M} g_{\mu\nu}(q) p^\mu p^\nu + V(q). \quad (1.394)$$

When trying to turn this expression into a Hamiltonian operator, we encounter the operator-ordering problem discussed in connection with Eq. (1.101). The correspondence principle requires replacing the momenta p_μ by the momentum operators \hat{p}_μ , but it does not specify the position of these operators with respect to the coordinates q^μ contained in the inverse metric $g^{\mu\nu}(q)$. An important constraint is provided by the required Hermiticity of the Hamiltonian operator, but this is not sufficient for a unique specification. We may, for instance, define the canonical Hamiltonian operator as

$$\hat{H}_{\text{can}} \equiv \frac{1}{2M} \hat{p}^\mu g_{\mu\nu}(q) \hat{p}^\nu + V(q), \quad (1.395)$$

in which the momentum operators have been arranged symmetrically around the inverse metric to achieve Hermiticity. This operator, however, is not equal to the

correct Schrödinger operator in (1.383). The kinetic term contains what we may call the *canonical Laplacian*

$$\Delta_{\text{can}} = (\partial_\mu + \frac{1}{2}\Gamma_\mu) g^{\mu\nu}(q) (\partial_\nu + \frac{1}{2}\Gamma_\nu). \quad (1.396)$$

It differs from the Laplace-Beltrami operator (1.381) in (1.383) by

$$\Delta - \Delta_{\text{can}} = -\frac{1}{2}\partial_\mu(g^{\mu\nu}\Gamma_\nu) - \frac{1}{4}g^{\mu\nu}\Gamma_\nu\Gamma_\mu. \quad (1.397)$$

The correct Hamiltonian operator could be obtained by suitably distributing pairs of dummy factors of $g^{1/4}$ and $g^{-1/4}$ symmetrically between the canonical operators [5]:

$$\hat{H} = \frac{1}{2M} g^{-1/4} \hat{p}_\mu g^{1/4} g^{\mu\nu}(q) g^{1/4} \hat{p}_\nu g^{-1/4} + V(q). \quad (1.398)$$

This operator has the same classical limit (1.394) as (1.395). Unfortunately, the correspondence principle does not specify how the classical factors have to be ordered before being replaced by operators.

The simplest system exhibiting the breakdown of the canonical quantization rules is a free particle in a plane described by radial coordinates $q^1 = r, q^2 = \varphi$:

$$x^1 = r \cos \varphi, \quad x^2 = r \sin \varphi. \quad (1.399)$$

Since the infinitesimal square distance is $ds^2 = dr^2 + r^2 d\varphi^2$, the metric reads

$$g_{\mu\nu} = \begin{pmatrix} 1 & 0 \\ 0 & r^2 \end{pmatrix}_{\mu\nu}. \quad (1.400)$$

It has a determinant

$$g = r^2 \quad (1.401)$$

and an inverse

$$g^{\mu\nu} = \begin{pmatrix} 1 & 0 \\ 0 & r^{-2} \end{pmatrix}^{\mu\nu}. \quad (1.402)$$

The Laplace-Beltrami operator becomes

$$\Delta = \frac{1}{r} \partial_r r \partial_r + \frac{1}{r^2} \partial_\varphi^2. \quad (1.403)$$

The canonical Laplacian, on the other hand, reads

$$\begin{aligned} \Delta_{\text{can}} &= (\partial_r + 1/2r)^2 + \frac{1}{r^2} \partial_\varphi^2 \\ &= \partial_r^2 + \frac{1}{r} \partial_r - \frac{1}{4r^2} + \frac{1}{r^2} \partial_\varphi^2. \end{aligned} \quad (1.404)$$

The discrepancy (1.397) is therefore

$$\Delta_{\text{can}} - \Delta = -\frac{1}{4r^2}. \quad (1.405)$$

Note that this discrepancy arises even though there is no apparent ordering problem in the naively quantized canonical expression $\hat{p}^\mu g_{\mu\nu}(q) \hat{p}^\nu$ in (1.404). Only the need to introduce dummy $g^{1/4}$ - and $g^{-1/4}$ -factors creates such problems, and a specification of the order is required to obtain the correct result.

If the Lagrangian coordinates q_i do not merely reparametrize a Euclidean space but specify the points of a general geometry, we cannot proceed as above and derive the Laplace-Beltrami operator by a coordinate transformation of a Cartesian Laplacian. With the canonical quantization rules being unreliable in curvilinear coordinates there are, at first sight, severe difficulties in quantizing such a system. This is why the literature contains many proposals for handling this problem [6]. Fortunately, a large class of non-Cartesian systems allows for a unique quantum-mechanical description on completely different grounds. These systems have the common property that their Hamiltonian can be expressed in terms of the generators of a group of motion in the general coordinate frame. For symmetry reasons, the correspondence principle must then be imposed not on the Poisson brackets of the canonical variables p and q , but on those of the group generators and the coordinates. The brackets containing two group generators specify the structure of the group, those containing a generator and a coordinate specify the defining representation of the group in configuration space. The replacement of these brackets by commutation rules constitutes the proper generalization of the canonical quantization from Cartesian to non-Cartesian coordinates. It is called *group quantization*. The replacement rule will be referred to as the *group correspondence principle*. The canonical commutation rules in Euclidean space may be viewed as a special case of the commutation rules between group generators, i.e., of the *Lie algebra* of the group. In a Cartesian coordinate frame, the group of motion is the Euclidean group containing translations and rotations. The generators of translations and rotations are the momenta and the angular momenta, respectively. According to the group correspondence principle, the Poisson brackets between the generators and the coordinates are to be replaced by commutation rules. Thus, in a Euclidean space, the commutation rules between group generators and coordinates lead to the canonical quantization rules, and this appears to be the deeper reason why the canonical rules are correct. In systems whose energy depends on generators of the group of motion other than those of translations, for instance on the angular momenta, the commutators between the generators have to be used for quantization rather than the canonical commutators between positions and momenta.

The prime examples for such systems are a particle on the surface of a sphere or a spinning top whose quantization will now be discussed.

1.14 Particle on the Surface of a Sphere

For a particle moving on the surface of a sphere of radius r with coordinates

$$x^1 = r \sin \theta \cos \varphi, \quad x^2 = r \sin \theta \sin \varphi, \quad x^3 = r \cos \theta, \quad (1.406)$$

the Lagrangian reads

$$L = \frac{Mr^2}{2}(\dot{\theta}^2 + \sin^2 \theta \dot{\varphi}^2). \quad (1.407)$$

The canonical momenta are

$$p_\theta = Mr^2\dot{\theta}, \quad p_\varphi = Mr^2 \sin^2 \theta \dot{\varphi}, \quad (1.408)$$

and the classical Hamiltonian is given by

$$H = \frac{1}{2Mr^2} \left(p_\theta^2 + \frac{1}{\sin^2 \theta} p_\varphi^2 \right). \quad (1.409)$$

According to the canonical quantization rules, the momenta should become operators

$$\hat{p}_\theta = -i\hbar \frac{1}{\sin^{1/2} \theta} \partial_\theta \sin^{1/2} \theta, \quad \hat{p}_\varphi = -i\hbar \partial_\varphi. \quad (1.410)$$

But as explained in the previous section, these momentum operators are not expected to give the correct Hamiltonian operator when inserted into the Hamiltonian (1.409). Moreover, there exists no proper coordinate transformation from the surface of the sphere to Cartesian coordinates¹⁹ such that a particle on a sphere cannot be treated via the safe Cartesian quantization rules (1.268):

$$\begin{aligned} [\hat{p}_i, \hat{x}^j] &= -i\hbar \delta_i^j, \\ [\hat{x}^i, \hat{x}^j] &= 0, \\ [\hat{p}_i, \hat{p}_j] &= 0. \end{aligned} \quad (1.411)$$

The only help comes from the group properties of the motion on the surface of the sphere. The angular momentum

$$\mathbf{L} = \mathbf{x} \times \mathbf{p} \quad (1.412)$$

can be quantized uniquely in Cartesian coordinates and becomes an operator

$$\hat{\mathbf{L}} = \hat{\mathbf{x}} \times \hat{\mathbf{p}} \quad (1.413)$$

whose components satisfy the commutation rules of the Lie algebra of the rotation group

$$[\hat{L}_i, \hat{L}_j] = i\hbar \hat{L}_k \quad (i, j, k \text{ cyclic}). \quad (1.414)$$

Note that there is no factor-ordering problem since the \hat{x}^i 's and the \hat{p}_i 's appear with different indices in each \hat{L}_k . An important property of the angular momentum

¹⁹There exist, however, certain infinitesimal nonholonomic coordinate transformations which are multivalued and can be used to transform infinitesimal distances in a curved space into those in a flat one. They are introduced and applied in Sections 10.2 and Appendix 10A, leading once more to the same quantum mechanics as the one described here.

operator is its homogeneity in \mathbf{x} . It has the consequence that when going from Cartesian to spherical coordinates

$$x^1 = r \sin \theta \cos \varphi, \quad x^2 = r \sin \theta \sin \varphi, \quad x^3 = r \cos \theta, \quad (1.415)$$

the radial coordinate cancels making the angular momentum a differential operator involving only the angles θ, φ :

$$\begin{aligned} \hat{L}_1 &= i\hbar (\sin \varphi \partial_\theta + \cot \theta \cos \varphi \partial_\varphi), \\ \hat{L}_2 &= -i\hbar (\cos \varphi \partial_\theta - \cot \theta \sin \varphi \partial_\varphi), \\ \hat{L}_3 &= -i\hbar \partial_\varphi. \end{aligned} \quad (1.416)$$

There is then a natural way of quantizing the system which makes use of these operators \hat{L}_i . We re-express the classical Hamiltonian (1.409) in terms of the classical angular momenta

$$\begin{aligned} L_1 &= Mr^2 \left(-\sin \varphi \dot{\theta} - \sin \theta \cos \theta \cos \varphi \dot{\varphi} \right), \\ L_2 &= Mr^2 \left(\cos \varphi \dot{\theta} - \sin \theta \cos \theta \sin \varphi \dot{\varphi} \right), \\ L_3 &= Mr^2 \sin^2 \theta \dot{\varphi} \end{aligned} \quad (1.417)$$

as

$$H = \frac{1}{2Mr^2} \mathbf{L}^2, \quad (1.418)$$

and replace the angular momenta by the operators (1.416). The result is the Hamiltonian operator:

$$\hat{H} = \frac{1}{2Mr^2} \hat{\mathbf{L}}^2 = -\frac{\hbar^2}{2Mr^2} \left[\frac{1}{\sin \theta} \partial_\theta (\sin \theta \partial_\theta) + \frac{1}{\sin^2 \theta} \partial_\varphi^2 \right]. \quad (1.419)$$

The eigenfunctions diagonalizing the rotation-invariant operator $\hat{\mathbf{L}}^2$ are well known. They can be chosen to diagonalize simultaneously one component of \hat{L}_i , for instance the third one, \hat{L}_3 , in which case they are equal to the spherical harmonics

$$Y_{lm}(\theta, \varphi) = (-1)^m \left[\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!} \right]^{1/2} P_l^m(\cos \theta) e^{im\varphi}, \quad (1.420)$$

with $P_l^m(z)$ being the associated Legendre polynomials

$$P_l^m(z) = \frac{1}{2^l l!} (1-z^2)^{m/2} \frac{d^{l+m}}{dx^{l+m}} (z^2-1)^l. \quad (1.421)$$

The spherical harmonics are orthonormal with respect to the rotation-invariant scalar product

$$\int_0^\pi d\theta \sin \theta \int_0^{2\pi} d\varphi Y_{lm}^*(\theta, \varphi) Y_{l'm'}(\theta, \varphi) = \delta_{ll'} \delta_{mm'}. \quad (1.422)$$

Two important lessons can be learned from this group quantization. First, the correct Hamiltonian operator (1.419) does not agree with the canonically quantized one which would be obtained by inserting Eqs. (1.410) into (1.409). The correct result would, however, arise by distributing dummy factors

$$g^{-1/4} = r^{-1} \sin^{-1/2}\theta, \quad g^{1/4} = r \sin^{1/2}\theta \quad (1.423)$$

between the canonical momentum operators as observed earlier in Eq. (1.398). Second, just as in the case of polar coordinates, the correct Hamiltonian operator is equal to

$$\hat{H} = -\frac{\hbar^2}{2M}\Delta, \quad (1.424)$$

where Δ is the Laplace-Beltrami operator associated with the metric

$$g_{\mu\nu} = r^2 \begin{pmatrix} 1 & 0 \\ 0 & \sin^2\theta \end{pmatrix}, \quad (1.425)$$

i.e.,

$$\Delta = \frac{1}{r^2} \left[\frac{1}{\sin\theta} \partial_\theta (\sin\theta \partial_\theta) + \frac{1}{\sin^2\theta} \partial_\varphi^2 \right]. \quad (1.426)$$

1.15 Spinning Top

For a spinning top, the optimal starting point is again not the classical Lagrangian but the Hamiltonian expressed in terms of the classical angular momenta. In the symmetric case in which two moments of inertia coincide, it is written as

$$H = \frac{1}{2I_\xi}(L_\xi^2 + L_\eta^2) + \frac{1}{2I_\zeta}L_\zeta^2, \quad (1.427)$$

where L_ξ, L_η, L_ζ are the components of the orbital angular momentum in the directions of the principal body axes with $I_\xi, I_\eta \equiv I_\xi, I_\zeta$ being the corresponding moments of inertia. The classical angular momentum of an aggregate of mass points is given by

$$\mathbf{L} = \sum_\nu \mathbf{x}_\nu \times \mathbf{p}_\nu, \quad (1.428)$$

where the sum over ν runs over all mass points. The angular momentum possesses a unique operator

$$\hat{\mathbf{L}} = \sum_\nu \hat{\mathbf{x}}_\nu \times \hat{\mathbf{p}}_\nu, \quad (1.429)$$

with the commutation rules (1.414) between the components \hat{L}_i . Since rotations do not change the distances between the mass points, they commute with the constraints of the rigid body. If the center of mass of the rigid body is placed at the origin, the only dynamical degrees of freedom are the orientations in space. They can uniquely be specified by the rotation matrix which brings the body from some standard orientation to the actual one. We may choose the standard orientation

to have the principal body axes aligned with the x, y, z -directions, respectively. An arbitrary orientation is obtained by applying all finite rotations to each point of the body. They are specified by the 3×3 orthonormal matrices R_{ij} . The space of these matrices has three degrees of freedom. It can be decomposed, omitting the matrix indices as

$$R(\alpha, \beta, \gamma) = R_3(\alpha)R_2(\beta)R_3(\gamma), \quad (1.430)$$

where $R_3(\alpha)$, $R_3(\gamma)$ are rotations around the z -axis by angles α , γ , respectively, and $R_2(\beta)$ is a rotation around the y -axis by β . These rotation matrices can be expressed as exponentials

$$R_i(\delta) \equiv e^{-i\delta L_i/\hbar}, \quad (1.431)$$

where δ is the rotation angle and L_i are the 3×3 matrix generators of the rotations with the elements

$$(L_i)_{jk} = -i\hbar\epsilon_{ijk}. \quad (1.432)$$

It is easy to check that these generators satisfy the commutation rules (1.414) of angular momentum operators. The angles α, β, γ are referred to as *Euler angles*.

The 3×3 rotation matrices make it possible to express the infinitesimal rotations around the three coordinate axes as differential operators of the three Euler angles. Let $\psi(R)$ be the wave function of the spinning top describing the probability amplitude of the different orientations which arise from a standard orientation by the rotation matrix $R = R(\alpha, \beta, \gamma)$. Under a further rotation by $R(\alpha', \beta', \gamma')$, the wave function goes over into $\psi'(R) = \psi(R^{-1}(\alpha', \beta', \gamma')R)$. The transformation may be described by a unitary differential operator

$$\hat{U}(\alpha', \beta', \gamma') \equiv e^{-i\alpha'\hat{L}_3} e^{-i\beta'\hat{L}_2} e^{-i\gamma'\hat{L}_3}, \quad (1.433)$$

where \hat{L}_i is the representation of the generators in terms of differential operators. To calculate these we note that the 3×3 -matrix $R^{-1}(\alpha, \beta, \gamma)$ has the following derivatives

$$\begin{aligned} -i\hbar\partial_\alpha R^{-1} &= R^{-1}L_3, \\ -i\hbar\partial_\beta R^{-1} &= R^{-1}(\cos\alpha L_2 - \sin\alpha L_1), \\ -i\hbar\partial_\gamma R^{-1} &= R^{-1}[\cos\beta L_3 + \sin\beta(\cos\alpha L_1 + \sin\alpha L_2)]. \end{aligned} \quad (1.434)$$

The first relation is trivial, the second follows from the rotation of the generator

$$e^{-i\alpha L_3/\hbar} L_2 e^{i\alpha L_3/\hbar} = \cos\alpha L_2 - \sin\alpha L_1, \quad (1.435)$$

which is a consequence of Lie's expansion formula (1.297) together with the commutation rules (1.432) of the 3×3 matrices L_i . The third requires, in addition, the rotation

$$e^{-i\beta L_2/\hbar} L_3 e^{i\beta L_2/\hbar} = \cos\beta L_3 + \sin\beta L_1. \quad (1.436)$$

Inverting the relations (1.434), we find the differential operators generating the rotations [7]:

$$\begin{aligned}\hat{L}_1 &= i\hbar \left(\cos \alpha \cot \beta \partial_\alpha + \sin \alpha \partial_\beta - \frac{\cos \alpha}{\sin \beta} \partial_\gamma \right), \\ \hat{L}_2 &= i\hbar \left(\sin \alpha \cot \beta \partial_\alpha - \cos \alpha \partial_\beta - \frac{\sin \alpha}{\sin \beta} \partial_\gamma \right), \\ \hat{L}_3 &= -i\hbar \partial_\alpha.\end{aligned}\quad (1.437)$$

After exponentiating these differential operators we derive

$$\begin{aligned}\hat{U}(\alpha', \beta', \gamma') R^{-1}(\alpha, \beta, \gamma) \hat{U}^{-1}(\alpha', \beta', \gamma') &= R^{-1}(\alpha, \beta, \gamma) R(\alpha', \beta', \gamma'), \\ \hat{U}(\alpha', \beta', \gamma') R(\alpha, \beta, \gamma) \hat{U}^{-1}(\alpha', \beta', \gamma') &= R^{-1}(\alpha', \beta', \gamma') R(\alpha, \beta, \gamma),\end{aligned}\quad (1.438)$$

so that $\hat{U}(\alpha', \beta', \gamma') \psi(R) = \psi'(R)$, as desired.

In the Hamiltonian (1.427), we need the components of $\hat{\mathbf{L}}$ along the body axes. They are obtained by rotating the 3×3 matrices L_i by $R(\alpha, \beta, \gamma)$ into

$$\begin{aligned}L_\xi &= RL_1R^{-1} = \cos \gamma \cos \beta (\cos \alpha L_1 + \sin \alpha L_2) \\ &\quad + \sin \gamma (\cos \alpha L_2 - \sin \alpha L_1) - \cos \gamma \sin \beta L_3, \\ L_\eta &= RL_2R^{-1} = -\sin \gamma \cos \beta (\cos \alpha L_1 + \sin \alpha L_2) \\ &\quad + \cos \gamma (\cos \alpha L_2 - \sin \alpha L_1) + \sin \gamma \sin \beta L_3, \\ L_\zeta &= RL_3R^{-1} = \cos \beta L_3 + \sin \beta (\cos \alpha L_1 + \sin \alpha L_2),\end{aligned}\quad (1.439)$$

and replacing $L_i \rightarrow \hat{L}_i$ in the final expressions. Inserting (1.437), we find the operators

$$\begin{aligned}\hat{L}_\xi &= i\hbar \left(-\cos \gamma \cot \beta \partial_\gamma - \sin \gamma \partial_\beta + \frac{\cos \gamma}{\sin \beta} \partial_\alpha \right), \\ \hat{L}_\eta &= i\hbar \left(\sin \gamma \cot \beta \partial_\gamma - \cos \gamma \partial_\beta - \frac{\sin \gamma}{\sin \beta} \partial_\alpha \right), \\ \hat{L}_\zeta &= -i\hbar \partial_\gamma.\end{aligned}\quad (1.440)$$

Note that these commutation rules have an opposite sign with respect to those in Eqs. (1.414) of the operators \hat{L}_i :²⁰

$$[\hat{L}_\xi, \hat{L}_\eta] = -i\hbar \hat{L}_\zeta, \quad \xi, \eta, \zeta = \text{cyclic.} \quad (1.441)$$

The sign is most simply understood by writing

$$\hat{L}_\xi = a_\xi^i \hat{L}_i, \quad \hat{L}_\eta = a_\eta^i \hat{L}_i, \quad \hat{L}_\zeta = a_\zeta^i \hat{L}_i, \quad (1.442)$$

²⁰When applied to functions not depending on α , then, after replacing $\beta \rightarrow \theta$ and $\gamma \rightarrow \varphi$, the operators agree with those in (1.416), up to the sign of \hat{L}_1 .

where $a_\xi^i, a_\eta^i, a_\zeta^i$, are the components of the body axes. Under rotations these behave like $[\hat{L}_i, a_\xi^j] = i\hbar\epsilon_{ijk}a_\xi^k$, i.e., they are vector operators. It is easy to check that this property produces the sign reversal in (1.441) with respect to (1.414).

The correspondence principle is now applied to the Hamiltonian in Eq. (1.427) by placing operator hats on the L_a 's. The energy spectrum and the wave functions can then be obtained by using only the group commutators between $\hat{L}_\xi, \hat{L}_\eta, \hat{L}_\zeta$. The spectrum is

$$E_{L\Lambda} = \hbar^2 \left[\frac{1}{2I_\xi} L(L+1) + \left(\frac{1}{2I_\zeta} - \frac{1}{2I_\xi} \right) \Lambda^2 \right], \quad (1.443)$$

where $L(L+1)$ with $L = 0, 1, 2, \dots$ are the eigenvalues of $\hat{\mathbf{L}}^2$, and $\Lambda = -L, \dots, L$ are the eigenvalues of \hat{L}_ζ . The wave functions are the representation functions of the rotation group. If the Euler angles α, β, γ are used to specify the orientation of the body axes, the wave functions are

$$\psi_{L\Lambda m}(\alpha, \beta, \gamma) = D_{m\Lambda}^L(-\alpha, -\beta, -\gamma). \quad (1.444)$$

Here m' are the eigenvalues of \hat{L}_3 , the magnetic quantum numbers, and $D_{m\Lambda}^L(\alpha, \beta, \gamma)$ are the representation matrices of angular momentum L . In accordance with (1.433), one may decompose

$$D_{m\Lambda}^L(\alpha, \beta, \gamma) = e^{-i(m\alpha+m'\gamma)} d_{mm'}^L(\beta), \quad (1.445)$$

with the matrices

$$\begin{aligned} d_{mm'}^L(\beta) &= \left[\frac{(L+m')!(L-m)!}{(L+m)!(L-m')} \right]^{1/2} \\ &\times \left(\cos \frac{\beta}{2} \right)^{m+m'} \left(-\sin \frac{\beta}{2} \right)^{m-m'} P_{L-m'}^{(m'-m, m'+m)}(\cos \beta). \end{aligned} \quad (1.446)$$

For $j = 1/2$, these form the spinor representation of the rotations around the y -axis

$$d_{m'm}^{1/2}(\beta) = \begin{pmatrix} \cos \beta/2 & -\sin \beta/2 \\ \sin \beta/2 & \cos \beta/2 \end{pmatrix}. \quad (1.447)$$

The indices have the order $+1/2, -1/2$. The full spinor representation function $D^{1/2}(\alpha, \beta, \gamma)$ in (1.445) is most easily obtained by inserting into the general expression (1.433) the representation matrices of spin $1/2$ for the generators \hat{L}_i with the commutation rules (1.414), the famous *Pauli spin matrices*:

$$\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (1.448)$$

Thus we can write

$$D^{1/2}(\alpha, \beta, \gamma) = e^{-i\alpha\sigma_3/2} e^{-i\beta\sigma_2/2} e^{-i\gamma\sigma_3/2}. \quad (1.449)$$

The first and the third factor yield the pure phase factors in (1.445). The function $d_{m'm}^{1/2}(\beta)$ is obtained by a simple power series expansion of $e^{-i\beta\sigma^2/2}$, using the fact that $(\sigma^2)^{2n} = 1$ and $(\sigma^2)^{2n+1} = \sigma^2$:

$$e^{-i\beta\sigma^2/2} = \cos \beta/2 - i \sin \beta/2 \sigma^2, \quad (1.450)$$

which is equal to (1.447).

For $j = 1$, the representation functions (1.446) form the vector representation

$$d_{m'm}^1(\beta) = \begin{pmatrix} \frac{1}{2}(1 + \cos \beta) & -\frac{1}{\sqrt{2}} \sin \beta & \frac{1}{2}(1 - \cos \beta) \\ \frac{1}{\sqrt{2}} \sin \beta & \cos \beta & -\frac{1}{\sqrt{2}} \sin \beta \\ \frac{1}{2}(1 - \cos \beta) & \frac{1}{\sqrt{2}} \sin \beta & \frac{1}{2}(1 + \cos \beta) \end{pmatrix}. \quad (1.451)$$

where the indices have the order $+1/2, -1/2$. The vector representation goes over into the ordinary rotation matrices $R_{ij}(\beta)$ by mapping the states $|1m\rangle$ onto the spherical unit vectors $\boldsymbol{\epsilon}(0) = \hat{\mathbf{z}}$, $\boldsymbol{\epsilon}(\pm 1) = \mp(\hat{\mathbf{x}} \pm i\hat{\mathbf{y}})/2$ using the matrix elements $\langle i|1m\rangle = \epsilon^i(m)$. Hence $R(\beta)\boldsymbol{\epsilon}(m) = \sum_{m'=-1}^1 \boldsymbol{\epsilon}(m')d_{m'm}^1(\beta)$.

The representation functions $D^1(\alpha, \beta, \gamma)$ can also be obtained by inserting into the general exponential (1.433) the representation matrices of spin 1 for the generators \hat{L}_i with the commutation rules (1.414). In Cartesian coordinates, these are simply $(\hat{L}_i)_{jk} = -i\epsilon_{ijk}$, where ϵ_{ijk} is the completely antisymmetric tensor with $\epsilon_{123} = 1$. In the spherical basis, these become $(\hat{L}_i)_{mm'} = \langle m|i\rangle(\hat{L}_i)_{ij}\langle j|m'\rangle = \epsilon_i^*(m)(\hat{L}_i)_{ij}\boldsymbol{\epsilon}_j(m')$. The exponential $(e^{-i\beta\hat{L}_2})_{mm'}$ is equal to (1.451).

The functions $P_l^{(\alpha, \beta)}(z)$ are the Jacobi polynomials [8], which can be expressed in terms of hypergeometric functions as

$$P_l^{(\alpha, \beta)} \equiv \frac{(-1)^l}{l!} \frac{\Gamma(l + \beta + 1)}{\Gamma(\beta + 1)} F(-l, l + 1 + \alpha + \beta; 1 + \beta; (1 + z)/2), \quad (1.452)$$

where

$$F(a, b, c; z) \equiv 1 + \frac{ab}{c}z + \frac{a(a+1)b(b+1)}{c(c+1)}\frac{z^2}{2!} + \dots \quad (1.453)$$

The rotation functions $d_{mm'}^L(\beta)$ satisfy the differential equation

$$\left(-\frac{d^2}{d\beta^2} - \cot \beta \frac{d}{d\beta} + \frac{m^2 + m'^2 - 2mm' \cos \beta}{\sin^2 \beta} \right) d_{mm'}^L(\beta) = L(L+1)d_{mm'}^L(\beta). \quad (1.454)$$

The scalar products of two wave functions have to be calculated with a measure of integration that is invariant under rotations:

$$\langle \psi_2 | \psi_1 \rangle \equiv \int_0^{2\pi} \int_0^\pi \int_0^{2\pi} d\alpha d\beta \sin \beta d\gamma \psi_2^*(\alpha, \beta, \gamma) \psi_1(\alpha, \beta, \gamma). \quad (1.455)$$

The above eigenstates (1.445) satisfy the orthogonality relation

$$\begin{aligned} \int_0^{2\pi} \int_0^\pi \int_0^{2\pi} d\alpha d\beta \sin \beta d\gamma D_{m'_1 m_1}^{L_1*}(\alpha, \beta, \gamma) D_{m'_2 m_2}^{L_2}(\alpha, \beta, \gamma) \\ = \delta_{m'_1 m'_2} \delta_{m_1 m_2} \delta_{L_1 L_2} \frac{8\pi^2}{2L_1 + 1}. \end{aligned} \quad (1.456)$$

Let us also contrast in this example the correct quantization via the commutation rules between group generators with the canonical approach which would start out with the classical Lagrangian. In terms of Euler angles, the Lagrangian reads

$$L = \frac{1}{2}[I_\xi(\omega_\xi^2 + \omega_\eta^2) + I_\zeta\omega_\zeta^2], \quad (1.457)$$

where $\omega_\xi, \omega_\eta, \omega_\zeta$ are the angular velocities measured along the principal axes of the top. To find these we note that the components in the rest system $\omega_1, \omega_2, \omega_3$ are obtained from the relation

$$\omega_k L_k = i\dot{R}R^{-1} \quad (1.458)$$

as

$$\begin{aligned} \omega_1 &= -\dot{\beta} \sin \alpha + \dot{\gamma} \sin \beta \cos \alpha, \\ \omega_2 &= \dot{\beta} \cos \alpha + \dot{\gamma} \sin \beta \sin \alpha, \\ \omega_3 &= \dot{\gamma} \cos \beta + \dot{\alpha}. \end{aligned} \quad (1.459)$$

After the rotation (1.439) into the body-fixed system, these become

$$\begin{aligned} \omega_\xi &= \dot{\beta} \sin \gamma - \dot{\alpha} \sin \beta \cos \gamma, \\ \omega_\eta &= \dot{\beta} \cos \gamma + \dot{\alpha} \sin \beta \sin \gamma, \\ \omega_\zeta &= \dot{\alpha} \cos \beta + \dot{\gamma}. \end{aligned} \quad (1.460)$$

Explicitly, the Lagrangian is

$$L = \frac{1}{2}[I_\xi(\dot{\beta}^2 + \dot{\alpha}^2 \sin^2 \beta) + I_\zeta(\dot{\alpha} \cos \beta + \dot{\gamma})^2]. \quad (1.461)$$

Considering α, β, γ as Lagrange coordinates q^μ with $\mu = 1, 2, 3$, this can be written in the form (1.387) with the Hessian metric [recall (1.12) and (1.388)]:

$$g_{\mu\nu} = \begin{pmatrix} I_\xi \sin^2 \beta + I_\zeta \cos^2 \beta & 0 & I_\zeta \cos \beta \\ 0 & I_\xi & 0 \\ I_\zeta \cos \beta & 0 & I_\zeta \end{pmatrix}, \quad (1.462)$$

whose determinant is

$$g = I_\xi^2 I_\zeta \sin^2 \beta. \quad (1.463)$$

Hence the measure $\int d^3q \sqrt{g}$ in the scalar product (1.384) agrees with the rotation-invariant measure (1.455) up to a trivial constant factor. Incidentally, this is also true for the asymmetric top with $I_\xi \neq I_\eta \neq I_\zeta$, where $g = I_\xi^2 I_\zeta \sin^2 \beta$, although the metric $g_{\mu\nu}$ is then much more complicated (see Appendix 1C).

The canonical momenta associated with the Lagrangian (1.457) are, according to (1.387),

$$\begin{aligned} p_\alpha &= \partial L / \partial \dot{\alpha} = I_\xi \dot{\alpha} \sin^2 \beta + I_\zeta \cos \beta (\dot{\alpha} \cos \beta + \dot{\gamma}), \\ p_\beta &= \partial L / \partial \dot{\beta} = I_\xi \dot{\beta}, \\ p_\gamma &= \partial L / \partial \dot{\gamma} = I_\zeta (\dot{\alpha} \cos \beta + \dot{\gamma}). \end{aligned} \quad (1.464)$$

After inverting the metric to

$$g^{\mu\nu} = \frac{1}{I_\xi \sin^2 \beta} \begin{pmatrix} 1 & 0 & -\cos \beta \\ 0 & \sin^2 \beta & 0 \\ -\cos \beta & 0 & \cos^2 \beta + I_\xi \sin^2 \beta / I_\zeta \end{pmatrix}^{\mu\nu}, \quad (1.465)$$

we find the classical Hamiltonian

$$H = \frac{1}{2} \left[\frac{1}{I_\xi} p_\beta^2 + \left(\frac{\cos^2 \beta}{I_\xi \sin^2 \beta} + \frac{1}{I_\zeta} \right) p_\gamma^2 + \frac{1}{I_\xi \sin^2 \beta} p_\alpha^2 - \frac{2 \cos \beta}{I_\xi \sin^2 \beta} p_\alpha p_\gamma \right]. \quad (1.466)$$

This Hamiltonian has no apparent ordering problem. One is therefore tempted to replace the momenta simply by the corresponding Hermitian operators which are, according to (1.391),

$$\begin{aligned} \hat{p}_\alpha &= -i\hbar \partial_\alpha, \\ \hat{p}_\beta &= -i\hbar (\sin \beta)^{-1/2} \partial_\beta (\sin \beta)^{1/2} = -i\hbar \left(\partial_\beta + \frac{1}{2} \cot \beta \right), \\ \hat{p}_\gamma &= -i\hbar \partial_\gamma. \end{aligned} \quad (1.467)$$

Inserting these into (1.466) gives the canonical Hamiltonian operator

$$\hat{H}_{\text{can}} = \hat{H} + \hat{H}_{\text{discr}}, \quad (1.468)$$

with

$$\begin{aligned} \hat{H} \equiv & -\frac{\hbar^2}{2I_\xi} \left[\partial_\beta^2 + \cot \beta \partial_\beta + \left(\frac{I_\xi}{I_\zeta} + \cot^2 \beta \right) \partial_\gamma^2 \right. \\ & \left. + \frac{1}{\sin^2 \beta} \partial_\alpha^2 - \frac{2 \cos \beta}{\sin^2 \beta} \partial_\alpha \partial_\gamma \right] \end{aligned} \quad (1.469)$$

and

$$\hat{H}_{\text{discr}} \equiv \frac{1}{2} (\partial_\beta \cot \beta) + \frac{1}{4} \cot^2 \beta = \frac{1}{4 \sin^2 \beta} - \frac{3}{4}. \quad (1.470)$$

The first term \hat{H} agrees with the correct quantum-mechanical operator derived above. Indeed, inserting the differential operators for the body-fixed angular momenta (1.440) into the Hamiltonian (1.427), we find \hat{H} . The term \hat{H}_{discr} is the discrepancy between the canonical and the correct Hamiltonian operator. It exists even though there is no apparent ordering problem, just as in the radial coordinate expression (1.404). The correct Hamiltonian could be obtained by replacing the classical p_β^2 term in H by the operator $g^{-1/4} \hat{p}_\beta g^{1/2} \hat{p}_\beta g^{-1/4}$, by analogy with the treatment of the radial coordinates in \hat{H} of Eq. (1.398).

As another similarity with the two-dimensional system in radial coordinates and the particle on the surface of the sphere, we observe that while the canonical quantization fails, the Hamiltonian operator of the symmetric spinning top is correctly given by the Laplace-Beltrami operator (1.381) after inserting the metric (1.462)

and the inverse (1.465). It is straightforward although tedious to verify that this is also true for the completely asymmetric top [which has quite a complicated metric given in Appendix 1C, see Eqs. (1C.2), and (1C.4)]. This is an important nontrivial result, since for a spinning top, the Lagrangian cannot be obtained by reparametrizing a particle in a Euclidean space with curvilinear coordinates. The result suggests that a replacement

$$g_{\mu\nu}(q)p^\mu p^\nu \rightarrow -\hbar^2 \Delta \quad (1.471)$$

produces the correct Hamiltonian operator in any non-Euclidean space.²¹

What is the characteristic non-Euclidean property of the α, β, γ space? As we shall see in detail in Chapter 10, the relevant quantity is the curvature scalar R . The exact definition will be found in Eq. (10.42). For the asymmetric spinning top we find (see Appendix 1C)

$$R = \frac{(I_\xi + I_\eta + I_\zeta)^2 - 2(I_\xi^2 + I_\eta^2 + I_\zeta^2)}{2I_\xi I_\eta I_\zeta}. \quad (1.472)$$

Thus, just like a particle on the surface of a sphere, the spinning top corresponds to a particle moving in a space with constant curvature. In this space, the correct correspondence principle can also be deduced from symmetry arguments. The geometry is most easily understood by observing that the α, β, γ space may be considered as the surface of a sphere in four dimensions, as we shall see in more detail in Chapter 8.

An important non-Euclidean space of physical interest is encountered in the context of general relativity. Originally, gravitating matter was assumed to move in a spacetime with an arbitrary local curvature. In newer developments of the theory one also allows for the presence of a nonvanishing torsion. In such a general situation, where the group quantization rule is inapplicable, the correspondence principle has always been a matter of controversy [see the references after (1.405)] to be resolved in this text. In Chapters 10 and 8 we shall present a new quantum equivalence principle which is based on an application of simple geometrical principles to path integrals and which will specify a natural and unique passage from classical to quantum mechanics in any coordinate frame.²² The configuration space may carry curvature and a certain class of torsions (gradient torsion). Several arguments suggest that our principle is correct. For the above systems with a Hamiltonian which can be expressed entirely in terms of generators of a group of motion in the underlying space, the new quantum equivalence principle will give the same results as the group quantization rule.

²¹If the space has curvature and no torsion, this is the correct answer. If torsion is present, the correct answer will be given in Chapters 10 and 8.

1.16 Scattering

Most observations of quantum phenomena are obtained from scattering processes of fundamental particles.

1.16.1 Scattering Matrix

Consider a particle impinging with a momentum \mathbf{p}_a and energy $E = E_a = \mathbf{p}_a^2/2M$ upon a nonzero potential concentrated around the origin. After a long time, it will be found far from the potential with some momentum \mathbf{p}_b . The energy will be unchanged: $E = E_b = \mathbf{p}_b^2/2M$. The probability amplitude for such a process is given by the time evolution amplitude in the momentum representation

$$\langle \mathbf{p}_b t_b | \mathbf{p}_a t_a \rangle \equiv \langle \mathbf{p}_b | e^{-i\hat{H}(t_b-t_a)/\hbar} | \mathbf{p}_a \rangle, \quad (1.473)$$

where the limit $t_b \rightarrow \infty$ and $t_a \rightarrow -\infty$ has to be taken. Long before and after the collision, this amplitude oscillates with a frequency $\omega = E/\hbar$ characteristic for free particles of energy E . In order to have a time-independent limit, we remove these oscillations, from (1.473), and define the scattering matrix (S -matrix) by the limit

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv \lim_{t_b-t_a \rightarrow \infty} e^{i(E_b t_b - E_a t_a)/\hbar} \langle \mathbf{p}_b | e^{-i\hat{H}(t_b-t_a)/\hbar} | \mathbf{p}_a \rangle. \quad (1.474)$$

Most of the impinging particles will not scatter at all, so that this amplitude must contain a leading term, which is separated as follows:

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle = \langle \mathbf{p}_b | \mathbf{p}_a \rangle + \langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle', \quad (1.475)$$

where

$$\langle \mathbf{p}_b | \mathbf{p}_a \rangle = \langle \mathbf{p}_b | e^{-i\hat{H}(t_b-t_a)/\hbar} | \mathbf{p}_a \rangle = (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p}_b - \mathbf{p}_a) \quad (1.476)$$

shows the normalization of the states [recall (1.186)]. This leading term is commonly subtracted from (1.474) to find the true scattering amplitude. Moreover, since potential scattering conserves energy, the remaining amplitude contains a δ -function ensuring energy conservation, and it is useful to divide this out, defining the so-called T -matrix by the decomposition

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p}_a - \mathbf{p}_a) - 2\pi\hbar i \delta(E_b - E_a) \langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle. \quad (1.477)$$

From the definition (1.474) and the hermiticity of \hat{H} it follows that the scattering matrix is a unitary matrix. This expresses the physical fact that the total probability of an incident particle to re-emerge at some time is unity (in quantum field theory the situation is more complicated due to emission and absorption processes).

In the basis states $|\mathbf{p}^m\rangle$ introduced in Eq. (1.180) which satisfy the completeness relation (1.182) and are normalized to unity in a finite volume V , the unitarity is expressed as

$$\sum_{\mathbf{m}'} \langle \mathbf{p}^m | \hat{S}^\dagger | \mathbf{p}^{\mathbf{m}'} \rangle \langle \mathbf{p}^{\mathbf{m}'} | \hat{S} | \mathbf{p}^{\mathbf{m}''} \rangle = \sum_{\mathbf{m}'} \langle \mathbf{p}^m | \hat{S} | \mathbf{p}^{\mathbf{m}'} \rangle \langle \mathbf{p}^{\mathbf{m}'} | \hat{S}^\dagger | \mathbf{p}^{\mathbf{m}''} \rangle = 1. \quad (1.478)$$

Remembering the relation (1.185) between the discrete states $|\mathbf{p}^m\rangle$ and their continuous limits $|\mathbf{p}\rangle$, we see that

$$\langle \mathbf{p}_b^{m'} | \hat{S} | \mathbf{p}_a^m \rangle \approx \frac{1}{L^3} \langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle, \quad (1.479)$$

where L^3 is the spatial volume, and \mathbf{p}_b^m and \mathbf{p}_a^m are the discrete momenta closest to \mathbf{p}_b and \mathbf{p}_a . In the continuous basis $|\mathbf{p}\rangle$, the unitarity relation reads

$$\int \frac{d^3p}{(2\pi\hbar)^3} \langle \mathbf{p}_b | \hat{S}^\dagger | \mathbf{p} \rangle \langle \mathbf{p} | \hat{S} | \mathbf{p}_a \rangle = \int \frac{d^3p}{(2\pi\hbar)^3} \langle \mathbf{p}_b | \hat{S} | \mathbf{p} \rangle \langle \mathbf{p} | \hat{S}^\dagger | \mathbf{p}_a \rangle = 1. \quad (1.480)$$

1.16.2 Cross Section

The absolute square of $\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle$ gives the probability $P_{\mathbf{p}_b \leftarrow \mathbf{p}_a}$ for the scattering from the initial momentum state \mathbf{p}_a to the final momentum state \mathbf{p}_b . Omitting the unscattered particles, we have

$$P_{\mathbf{p}_b \leftarrow \mathbf{p}_a} = \frac{1}{L^6} 2\pi\hbar\delta(0) 2\pi\hbar\delta(E_b - E_a) |\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle|^2. \quad (1.481)$$

The factor $\delta(0)$ at zero energy is made finite by imagining the scattering process to take place with an incident time-independent plane wave over a finite total time T . Then $2\pi\hbar\delta(0) = \int dt e^{iEt/\hbar} |_{E=0} = T$, and the probability is proportional to the time T :

$$P_{\mathbf{p}_b \leftarrow \mathbf{p}_a} = \frac{1}{L^6} T 2\pi\hbar\delta(E_b - E_a) |\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle|^2. \quad (1.482)$$

By summing this over all discrete final momenta, or equivalently, by integrating this over the phase space of the final momenta [recall (1.184)], we find the total probability per unit time for the scattering to take place

$$\frac{dP}{dt} = \frac{1}{L^6} \int \frac{d^3p_b L^3}{(2\pi\hbar)^3} 2\pi\hbar\delta(E_b - E_a) |\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle|^2. \quad (1.483)$$

The momentum integral can be split into an integral over the final energy and the final solid angle. For non-relativistic particles, this goes as follows

$$\int \frac{d^3p_b}{(2\pi\hbar)^3} = \frac{1}{(2\pi\hbar)^3} \frac{M}{(2\pi\hbar)^3} \int d\Omega \int_0^\infty dE_b p_b, \quad (1.484)$$

where $d\Omega = d\phi_b d\cos\theta_b$ is the element of solid angle into which the particle is scattered. The energy integral removes the δ -function in (1.483), and makes p_b equal to p_a .

The differential scattering cross section $d\sigma/d\Omega$ is defined as the probability that a single impinging particle ends up in a solid angle $d\Omega$ per unit time and unit current density. From (1.483) we identify

$$\frac{d\sigma}{d\Omega} = \frac{d\dot{P}}{d\Omega} \frac{1}{j} = \frac{1}{L^3} \frac{Mp}{(2\pi\hbar)^3} 2\pi\hbar |T_{\mathbf{p}_b \mathbf{p}_a}|^2 \frac{1}{j}, \quad (1.485)$$

where we have set

$$\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle \equiv T_{\mathbf{p}_b \mathbf{p}_a}, \quad (1.486)$$

for brevity. In a volume L^3 , the current density of a single impinging particle is given by the velocity $v = p/M$ as

$$j = \frac{1}{L^3} \frac{p}{M}, \quad (1.487)$$

so that the differential cross section becomes

$$\frac{d\sigma}{d\Omega} = \frac{M^2}{(2\pi\hbar)^2} |T_{\mathbf{p}_b \mathbf{p}_a}|^2. \quad (1.488)$$

If the scattered particle moves relativistically, we have to replace the constant mass M in (1.484) by $E = \sqrt{p^2 + M^2}$ inside the momentum integral, where $p = |\mathbf{p}|$, so that

$$\begin{aligned} \int \frac{d^3p}{(2\pi\hbar)^3} &= \frac{1}{(2\pi\hbar)^3} \int d\Omega \int_0^\infty dp p^2 \\ &= \frac{1}{(2\pi\hbar)^3} \int d\Omega \int_0^\infty dE E p. \end{aligned} \quad (1.489)$$

In the relativistic case, the initial current density is not proportional to p/M but to the relativistic velocity $v = p/E$ so that

$$j = \frac{1}{L^3} \frac{p}{E}. \quad (1.490)$$

Hence the cross section becomes

$$\frac{d\sigma}{d\Omega} = \frac{E^2}{(2\pi\hbar)^2} |T_{\mathbf{p}_b \mathbf{p}_a}|^2. \quad (1.491)$$

1.16.3 Born Approximation

To lowest order in the interaction strength, the operator \hat{S} in (1.474) is

$$\hat{S} \approx 1 - i\hat{V}/\hbar. \quad (1.492)$$

For a time-independent scattering potential, this implies

$$T_{\mathbf{p}_b \mathbf{p}_a} \approx V_{\mathbf{p}_b \mathbf{p}_a} / \hbar, \quad (1.493)$$

where

$$V_{\mathbf{p}_b \mathbf{p}_a} \equiv \langle \mathbf{p}_b | \hat{V} | \mathbf{p}_a \rangle = \int d^3x e^{i(\mathbf{p}_b - \mathbf{p}_a) \cdot \mathbf{x} / \hbar} V(\mathbf{x}) = \tilde{V}(\mathbf{p}_b - \mathbf{p}_a) \quad (1.494)$$

is a function of the *momentum transfer* $\mathbf{q} \equiv \mathbf{p}_b - \mathbf{p}_a$ only. Then (1.491) reduces to the so called *Born approximation* (Born 1926)

$$\frac{d\sigma}{d\Omega} \approx \frac{E^2}{(2\pi\hbar)^2\hbar^2} |V_{\mathbf{p}_b\mathbf{p}_a}|^2. \quad (1.495)$$

The amplitude whose square is equal to the differential cross section is usually denoted by $f_{\mathbf{p}_b\mathbf{p}_a}$, i.e., one writes

$$\frac{d\sigma}{d\Omega} = |f_{\mathbf{p}_b\mathbf{p}_a}|^2. \quad (1.496)$$

By comparison with (1.495) we identify

$$f_{\mathbf{p}_b\mathbf{p}_a} \equiv -\frac{M}{2\pi\hbar} R_{\mathbf{p}_b\mathbf{p}_a}, \quad (1.497)$$

where we have chosen the sign to agree with the convention in the textbook by Landau and Lifshitz [9].

1.16.4 Partial Wave Expansion and Eikonal Approximation

The scattering amplitude is usually expanded in partial waves with the help of Legendre polynomials $P_l(z) \equiv P_l^0(z)$ [see (1.421)] as

$$f_{\mathbf{p}_b\mathbf{p}_a} = \frac{\hbar}{2ip} \sum_{l=0}^{\infty} (2l+1) P_l(\cos\theta) \left(e^{2i\delta_l(p)} - 1 \right) \quad (1.498)$$

where $p \equiv |\mathbf{p}| = |\mathbf{p}_b| = |\mathbf{p}_a|$ and θ is the scattering defined by $\cos\theta \equiv \mathbf{p}_b\mathbf{p}_a/|\mathbf{p}_b||\mathbf{p}_a|$. In terms of θ , the momentum transfer $\mathbf{q} = \mathbf{p}_b - \mathbf{p}_a$ has the size $|\mathbf{q}| = 2p \sin(\theta/2)$.

For small θ , we can use the asymptotic form of the Legendre polynomials²³

$$P_l^{-m}(\cos\theta) \approx \frac{1}{l^m} J_m(l\theta), \quad (1.499)$$

to rewrite (1.498) approximately as an integral

$$f_{\mathbf{p}_b\mathbf{p}_a}^{\text{ei}} = \frac{p}{i\hbar} \int db b J_0(qb) \left\{ \exp \left[2i\delta_{pb/\hbar}(p) \right] - 1 \right\}, \quad (1.500)$$

where $b \equiv l\hbar/p$ is the so called *impact parameter* of the scattering process. This is the *eikonal approximation* to the scattering amplitude. As an example, consider Coulomb scattering where $V(r) = Ze^2/r$ and (2.751) yields

$$\chi_{\mathbf{b},\mathbf{P}}^{\text{ei}}[\mathbf{v}] = -\frac{Ze^2M}{|\mathbf{P}|} \frac{1}{\hbar} \int_{-\infty}^{\infty} dz \frac{1}{\sqrt{b^2 + z^2}}. \quad (1.501)$$

²³M. Abramowitz and I. Stegun, op. cit., Formula 9.1.71.

The integral diverges logarithmically, but in a physical sample, the potential is screened at some distance R by opposite charges. Performing the integral up to R yields

$$\begin{aligned}\chi_{\mathbf{b},\mathbf{P}}^{\text{ei}}[\mathbf{v}] &= -\frac{Ze^2M}{|\mathbf{P}|} \frac{1}{\hbar} \int_b^R dr \frac{1}{\sqrt{r^2-b^2}} = -\frac{Ze^2M}{|\mathbf{P}|} \frac{1}{\hbar} \log \frac{R + \sqrt{R^2-b^2}}{b} \\ &\approx -2\frac{Ze^2M}{|\mathbf{P}|} \frac{1}{\hbar} \log \frac{2R}{b}.\end{aligned}\quad (1.502)$$

This implies

$$\exp(\chi_{\mathbf{b},\mathbf{P}}^{\text{ei}}) \approx \left(\frac{b}{2R}\right)^{2i\gamma}, \quad (1.503)$$

where

$$\gamma \equiv \frac{Ze^2M}{|\mathbf{P}|} \frac{1}{\hbar} \quad (1.504)$$

is a dimensionless quantity since $e^2 = \hbar c \alpha$ where α is the dimensionless *fine-structure constant*²⁴

$$\alpha = \frac{e^2}{\hbar c} = 1/137.0359979\dots \quad (1.505)$$

The integral over the impact parameter in (1.500) can now be performed and yields

$$f_{\mathbf{P}_b\mathbf{P}_a}^{\text{ei}} \approx \frac{\hbar}{2ip} \frac{1}{\sin^{2+2i\gamma}(\theta/2)} \frac{\Gamma(1+i\gamma)}{\Gamma(-i\gamma)} e^{-2i\gamma \log(2pR/\hbar)}. \quad (1.506)$$

Remarkably, this is the exact quantum mechanical amplitude of Coulomb scattering, except for the last phase factor which accounts for a finite screening length. This amplitude contains poles at momentum variables $p = p_n$ whenever

$$i\gamma_n \equiv \frac{Ze^2M\hbar}{p_n} = -n, \quad n = 1, 2, 3, \dots \quad (1.507)$$

This corresponds to energies

$$E^{(n)} = -\frac{p_n^2}{2M} = -\frac{MZ^2e^4}{\hbar^2} \frac{1}{2n^2}, \quad (1.508)$$

which are the well-known energy values of hydrogen-like atoms with nuclear charge Ze . The prefactor $E_H \equiv e^2/a_H = Me^4/\hbar^2 = 4.359 \times 10^{-11} \text{ erg} = 27.210 \text{ eV}$, is equal to twice the *Rydberg energy* (see also p. 964).

²⁴Throughout this book we use electromagnetic units where the electric field $\mathbf{E} = -\nabla\phi$ has the energy density $\mathcal{H} = \mathbf{E}^2/8\pi + \rho\phi$, where ρ is the charge density, so that $\nabla \cdot \mathbf{E} = 4\pi\rho$ and $e^2 = \hbar c \alpha$. The fine-structure constant is measured most precisely via the *quantum Hall effect*, see M.E. Cage et al., IEEE Trans. Instrum. Meas. 38, 284 (1989). The magnetic field satisfies Ampère's law $\nabla \times \mathbf{B} = 4\pi\mathbf{j}$, where \mathbf{j} is the current density.

1.16.5 Scattering Amplitude from Time Evolution Amplitude

There exists a heuristic formula expressing the scattering amplitude as a limit of the time evolution amplitude. For this we express the δ -function in the energy as a large-time limit

$$\delta(E_b - E_a) = \frac{M}{p_b} \delta(p_b - p_a) = \frac{M}{p_b} \lim_{t_b \rightarrow \infty} \left(\frac{t_b}{2\pi\hbar M/i} \right)^{1/2} \exp \left[-\frac{i}{\hbar} \frac{t_b}{2M} (p_b - p_a)^2 \right], \quad (1.509)$$

where $p_b = |\mathbf{p}_b|$. Inserting this into Eq. (1.477) and setting sloppily $p_b = p_a$ for elastic scattering, the δ -function is removed and we obtain the following expression for the scattering amplitude

$$f_{\mathbf{p}_b \mathbf{p}_a} = \frac{p_b}{M} \frac{\sqrt{2\pi\hbar M/i}^3}{(2\pi\hbar)^3} \lim_{t_b \rightarrow \infty} \frac{1}{t_b^{1/2}} e^{iE_b(t_b - t_a)/\hbar} [\langle \mathbf{p}_b t_b | \mathbf{p}_a t_a \rangle - \langle \mathbf{p}_b | \mathbf{p}_a \rangle]. \quad (1.510)$$

This treatment of a δ -function is certainly unsatisfactory. A satisfactory treatment will be given in the path integral formulation in Section 2.22. At the present stage, we may proceed with more care with the following operator calculation. We rewrite the limit (1.474) with the help of the time evolution operator (2.5) as follows:

$$\begin{aligned} \langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle &\equiv \lim_{t_b \rightarrow \infty} e^{i(E_b t_b - E_a t_a)/\hbar} \langle \mathbf{p}_b t_b | \mathbf{p}_a t_a \rangle \\ &= \lim_{t_b, -t_a \rightarrow \infty} \langle \mathbf{p}_b | \hat{U}_I(t_b, t_a) | \mathbf{p}_a \rangle, \end{aligned} \quad (1.511)$$

where $\hat{U}_I(t_b, t_a)$ is the time evolution operator in Dirac's interaction picture (1.286).

1.16.6 Lippmann-Schwinger Equation

From the definition (1.286) it follows that the operator $\hat{U}_I(t_b, t_a)$ satisfies the same composition law (1.254) as the ordinary time evolution operator $\hat{U}(t, t_a)$:

$$\hat{U}_I(t, t_a) = \hat{U}_I(t, t_b) \hat{U}_I(t_b, t_a). \quad (1.512)$$

Now we observe that

$$e^{-iH_0 t/\hbar} \hat{U}_I(t, t_a) = e^{-iH t/\hbar} \hat{U}_I(0, t_a) = \hat{U}_I(0, t_a - t) e^{-iH_0 t/\hbar}, \quad (1.513)$$

so that in the limit $t_a \rightarrow -\infty$

$$e^{-iH_0 t/\hbar} \hat{U}_I(t, t_a) = e^{-iH t/\hbar} \hat{U}_I(0, t_a) \longrightarrow \hat{U}_I(0, t_a) e^{-iH_0 t/\hbar}, \quad (1.514)$$

and therefore

$$\lim_{t_a \rightarrow -\infty} \hat{U}_I(t_b, t_a) = \lim_{t_a \rightarrow -\infty} e^{iH_0 t_b/\hbar} e^{-iH t_b/\hbar} \hat{U}_I(0, t_a) = \lim_{t_a \rightarrow -\infty} e^{iH_0 t_b/\hbar} \hat{U}_I(0, t_a) e^{-iH_0 t_b/\hbar}, \quad (1.515)$$

which allows us to rewrite the scattering matrix (1.511) as

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv \lim_{t_b, -t_a \rightarrow \infty} e^{i(E_b - E_a)t_b/\hbar} \langle \mathbf{p}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle. \quad (1.516)$$

Note that in contrast to (1.474), the time evolution of the initial state goes now only over the negative time axis rather than the full one.

Taking the matrix elements of Eq. (1.291) between free-particle states $\langle \mathbf{p}_b |$ and $| \mathbf{p}_b \rangle$, and using Eqs. (1.291) and (1.514), we obtain at $t_b = 0$

$$\langle \mathbf{p}_b | \hat{U}_I(0, t_a) | \mathbf{p}_b \rangle = \langle \mathbf{p}_b | \mathbf{p}_b \rangle - \frac{i}{\hbar} \int_{-\infty}^0 dt e^{i(E_b - E_a - i\eta)t/\hbar} \langle \mathbf{p}_b | \hat{V} \hat{U}_I(0, t_a) | \mathbf{p}_b \rangle. \quad (1.517)$$

A small damping factor $e^{\eta t/\hbar}$ is inserted to ensure convergence at $t = -\infty$. For a time-independent potential, the integral can be done and yields

$$\langle \mathbf{p}_b | \hat{U}_I(0, t_a) | \mathbf{p}_b \rangle = \langle \mathbf{p}_b | \mathbf{p}_b \rangle - \frac{1}{E_b - E_a - i\eta} \langle \mathbf{p}_b | \hat{V} \hat{U}_I(0, t_a) | \mathbf{p}_b \rangle. \quad (1.518)$$

This is the famous *Lippmann-Schwinger equation*. Inserting this into (1.516), we obtain the equation for the scattering matrix

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle = \lim_{t_b, -t_a \rightarrow \infty} e^{i(E_b - E_a)t_b} \left[\langle \mathbf{p}_b | \mathbf{p}_a \rangle - \frac{1}{E_b - E_a - i\eta} \langle \mathbf{p}_b | \hat{V} \hat{U}_I(0, t_a) | \mathbf{p}_b \rangle \right]. \quad (1.519)$$

The first term in brackets is nonzero only if the momenta \mathbf{p}_a and \mathbf{p}_b are equal, in which case also the energies are equal, $E_b = E_a$, so that the prefactor can be set equal to one. In front of the second term, the prefactor oscillates rapidly as the time t_b grows large, making any finite function of E_b vanish, as a consequence of the Riemann-Lebesgue lemma. The second term contains, however, a pole at $E_b = E_a$ for which the limit has to be done more carefully. The prefactor has the property

$$\lim_{t_b \rightarrow \infty} \frac{e^{i(E_b - E_a)t_b/\hbar}}{E_b - E_a - i\eta} = \begin{cases} 0, & E_b \neq E_a, \\ i/\eta, & E_b = E_a. \end{cases} \quad (1.520)$$

It is easy to see that this property defines a δ -function in the energy:

$$\lim_{t_b \rightarrow \infty} \frac{e^{i(E_b - E_a)t_b/\hbar}}{E_b - E_a - i\eta} = 2\pi i \delta(E_b - E_a). \quad (1.521)$$

Indeed, let us integrate the left-hand side together with a smooth function $f(E_b)$, and set

$$E_b \equiv E_a + \xi/t_b. \quad (1.522)$$

Then the E_b -integral is rewritten as

$$\int_{-\infty}^{\infty} d\xi \frac{e^{i\xi}}{\xi + i\eta} f(E_a + \xi/t_a). \quad (1.523)$$

In the limit of large t_a , the function $f(E_a)$ can be taken out of the integral and the contour of integration can then be closed in the upper half of the complex energy plane, yielding $2\pi i$. Thus we obtain from (1.519) the formula (1.477), with the T -matrix

$$\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle = \frac{1}{\hbar} \langle \mathbf{p}_b | \hat{V} \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle. \quad (1.524)$$

For a small potential \hat{V} , we approximate $\hat{U}_I(0, t_a) \approx 1$, and find the Born approximation (1.493).

The Lippmann-Schwinger equation can be recast as an integral equation for the T -matrix. Multiplying the original equation (1.518) by the matrix $\langle \mathbf{p}_b | \hat{V} | \mathbf{p}_a \rangle = V_{\mathbf{p}_b \mathbf{p}_a}$ from the left, we obtain

$$T_{\mathbf{p}_b \mathbf{p}_a} = V_{\mathbf{p}_b \mathbf{p}_a} - \int \frac{d^3 p_c}{(2\pi\hbar)^3} V_{\mathbf{p}_b \mathbf{p}_c} \frac{1}{E_c - E_a - i\eta} T_{\mathbf{p}_c \mathbf{p}_a}. \quad (1.525)$$

To extract physical information from the T -matrix (1.524) it is useful to analyze the behavior of the interacting state $\hat{U}_I(0, t_a) | \mathbf{p}_a \rangle$ in \mathbf{x} -space. From Eq. (1.514), we see that it is an eigenstate of the full Hamiltonian operator \hat{H} with the initial energy E_a . Multiplying this state by $\langle \mathbf{x} |$ from the left, and inserting a complete set of momentum eigenstates, we calculate

$$\langle \mathbf{x} | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle = \int \frac{d^3 p}{(2\pi\hbar)^3} \langle \mathbf{x} | \mathbf{p} \rangle \langle \mathbf{p} | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle = \int \frac{d^3 p}{(2\pi\hbar)^3} \langle \mathbf{x} | \mathbf{p} \rangle \langle \mathbf{p} | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle.$$

Using Eq. (1.518), this becomes

$$\langle \mathbf{x} | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle = \langle \mathbf{x} | \mathbf{p}_a \rangle + \int d^3 x' \int \frac{d^3 p_b}{(2\pi\hbar)^3} \frac{e^{i\mathbf{p}_b(\mathbf{x}-\mathbf{x}')/\hbar}}{E_a - \mathbf{p}_b^2/2M + i\eta} V(\mathbf{x}') \langle \mathbf{x}' | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle. \quad (1.526)$$

The function

$$(\mathbf{x} | \mathbf{x}')_{E_a} = \int \frac{d^3 p_b}{(2\pi\hbar)^3} e^{i\mathbf{p}_b(\mathbf{x}-\mathbf{x}')/\hbar} \frac{i\hbar}{E_a - \mathbf{p}_b^2/2M + i\eta} \quad (1.527)$$

is recognized as the fixed-energy amplitude (1.344) of the free particle. In three dimensions it reads [see (1.359)]

$$(\mathbf{x} | \mathbf{x}')_{E_a} = -\frac{2Mi}{\hbar} \frac{e^{ip_a|\mathbf{x}-\mathbf{x}'|/\hbar}}{4\pi|\mathbf{x}-\mathbf{x}'|}, \quad p_a = \sqrt{2ME_a}. \quad (1.528)$$

In order to find the scattering amplitude, we consider the wave function (1.526) far away from the scattering center, i.e., at large $|\mathbf{x}|$. Under the assumption that $V(\mathbf{x}')$ is nonzero only for small \mathbf{x}' , we approximate $|\mathbf{x}-\mathbf{x}'| \approx r - \hat{\mathbf{x}}\mathbf{x}'$, where $\hat{\mathbf{x}}$ is the unit vector in the direction of \mathbf{x} , and (1.526) becomes

$$\langle \mathbf{x} | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle \approx e^{i\mathbf{p}_a \mathbf{x} / \hbar} - \frac{e^{ip_a r}}{4\pi r} \int d^4 x' e^{-ip_a \hat{\mathbf{x}} \mathbf{x}'} \frac{2M}{\hbar^2} V(\mathbf{x}') \langle \mathbf{x}' | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle. \quad (1.529)$$

In the limit $t_a \rightarrow -\infty$, the factor multiplying the spherical wave factor $e^{ip_a r/\hbar}/r$ is the scattering amplitude $f(\hat{\mathbf{x}})_{\mathbf{p}_a}$, whose absolute square gives the cross section. For scattering to a final momentum \mathbf{p}_b , the outgoing particles are detected far away from the scattering center in the direction $\hat{\mathbf{x}} = \hat{\mathbf{p}}_b$. Because of energy conservation, we may set $p_a \hat{\mathbf{x}} = \mathbf{p}_b$ and obtain the formula

$$f_{\mathbf{p}_b \mathbf{p}_a} = \lim_{t_a \rightarrow -\infty} -\frac{M}{2\pi\hbar^2} \int d^4x_b e^{-i\mathbf{p}_b \mathbf{x}_b} V(\mathbf{x}_b) \langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle. \quad (1.530)$$

By studying the interacting state $\hat{U}_I(0, t_a) | \mathbf{p}_a \rangle$ in \mathbf{x} -space, we have avoided the singular δ -function of energy conservation.

We are now prepared to derive formula (1.510) for the scattering amplitude. We observe that in the limit $t_a \rightarrow -\infty$, the amplitude $\langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle$ can be obtained from the time evolution amplitude $\langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle$ as follows:

$$\begin{aligned} \langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle &= \langle \mathbf{x}_b | \hat{U}(0, t_a) | \mathbf{p}_a \rangle e^{-iE_a t_a/\hbar} \\ &= \lim_{t_a \rightarrow -\infty} \left(\frac{-2\pi i \hbar t_a}{M} \right)^{3/2} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle e^{i(\mathbf{p}_a \mathbf{x}_a - p_a^2 t_a/2M)/\hbar} \Big|_{\mathbf{x}_a = \mathbf{p}_a t_a/M}. \end{aligned} \quad (1.531)$$

This follows directly from the Fourier transformation

$$\langle \mathbf{x}_b | \hat{U}(0, t_a) | \mathbf{p}_a \rangle e^{-iE_a t_a/\hbar} = \int d^3x_a \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle e^{i(\mathbf{p}_a \mathbf{x}_a - p_a^2 t_a/2M)/\hbar}, \quad (1.532)$$

by substituting the dummy integration variable \mathbf{x}_a by $\mathbf{p}t_a/M$. Then the right-hand side becomes

$$\left(\frac{-t_a}{M} \right)^3 \int d^3p \langle \mathbf{x}_b 0 | \mathbf{p} t_a t_a \rangle e^{i(\mathbf{p}_a \mathbf{p} - p_a^2) t_a/2M\hbar}. \quad (1.533)$$

Now, for large $-t_a$, the momentum integration is squeezed to $\mathbf{p} = \mathbf{p}_a$, and we obtain (1.531). The appropriate limiting formula for the δ -function

$$\delta^{(D)}(\mathbf{p}_b - \mathbf{p}_a) = \lim_{t_a \rightarrow -\infty} \frac{(-t_a)^{D/2}}{\sqrt{2\pi i \hbar M}^D} \exp \left\{ -\frac{i}{\hbar} \frac{t_a}{2M} (\mathbf{p}_b - \mathbf{p}_a)^2 \right\} \quad (1.534)$$

is easily obtained from Eq. (1.342) by an obvious substitution of variables. Its complex conjugate for $D = 1$ was written down before in Eq. (1.509) with t_a replaced by $-t_b$. The exponential on the right-hand side can just as well be multiplied by a factor $e^{i(p_b^2 - p_a^2)^2/2M\hbar}$ which is unity when both sides are nonzero, so that it becomes $e^{-i(\mathbf{p}_a \mathbf{p} - p_a^2) t_a/2M\hbar}$. In this way we obtain a representation of the δ -function by which the Fourier integral (1.533) goes over into (1.531). The phase factor $e^{i(\mathbf{p}_a \mathbf{x}_a - p_a^2 t_a/2M)/\hbar}$ on the right-hand side of Eq. (1.531), which is unity in the limit performed in that equation, is kept in Eq. (4.580) for later convenience.

Formula (1.531) is a reliable starting point for extracting the scattering amplitude $f_{\mathbf{p}_b \mathbf{p}_a}$ from the time evolution amplitude in \mathbf{x} -space $\langle \mathbf{x}_b 0 | \mathbf{x}_a t_a \rangle$ at $\mathbf{x}_a = \mathbf{p}_a t_a/M$ by extracting the coefficient of the outgoing spherical wave $e^{ip_a r/\hbar}/r$.

As a cross check we insert the free-particle amplitude (1.341) into (1.531) and obtain the free undisturbed wave function $e^{i\mathbf{p}_a \mathbf{x}}$, which is the correct first term in Eq. (1.526) associated with unscattered particles.

1.17 Classical and Quantum Statistics

Consider a physical system with a constant number of particles N whose Hamiltonian has no explicit time dependence. If it is brought into contact with a thermal reservoir at a temperature T and has reached equilibrium, its thermodynamic properties can be obtained through the following rules: At the level of classical mechanics, each volume element in phase space

$$\frac{dp dq}{h} = \frac{dp dq}{2\pi\hbar} \quad (1.535)$$

is occupied with a probability proportional to the *Boltzmann factor*

$$e^{-H(p,q)/k_B T}, \quad (1.536)$$

where k_B is the *Boltzmann constant*,

$$k_B = 1.3806221(59) \times 10^{-16} \text{ erg/Kelvin}. \quad (1.537)$$

The number in parentheses indicates the experimental uncertainty of the two digits in front of it. The quantity $1/k_B T$ has the dimension of an inverse energy and is commonly denoted by β . It will be called the *inverse temperature*, forgetting about the factor k_B . In fact, we shall sometimes take T to be measured in energy units k_B times Kelvin rather than in Kelvin. Then we may drop k_B in all formulas.

The integral over the Boltzmann factors of all phase space elements,²⁵

$$Z_{\text{cl}}(T) \equiv \int \frac{dp dq}{2\pi\hbar} e^{-H(p,q)/k_B T}, \quad (1.538)$$

is called the *classical partition function*. It contains all classical thermodynamic information of the system. Of course, for a general Hamiltonian system with many degrees of freedom, the phase space integral is $\prod_n \int dp_n dq_n / 2\pi\hbar$. The reader may wonder why an expression containing Planck's quantum \hbar is called *classical*. The reason is that \hbar can really be omitted in calculating any thermodynamic average. In classical statistics it merely supplies us with an irrelevant normalization factor which makes Z dimensionless.

1.17.1 Canonical Ensemble

In quantum statistics, the Hamiltonian is replaced by the operator \hat{H} and the integral over phase space by the trace in the Hilbert space. This leads to the *quantum-statistical partition function*

$$Z(T) \equiv \text{Tr} \left(e^{-\hat{H}/k_B T} \right) \equiv \text{Tr} \left(e^{-H(\hat{p}, \hat{x})/k_B T} \right), \quad (1.539)$$

²⁵In the sequel we shall always work at a fixed volume V and therefore suppress the argument V everywhere.

where $\text{Tr } \hat{O}$ denotes the trace of the operator \hat{O} . If \hat{H} is an N -particle Schrödinger Hamiltonian, the quantum-statistical system is referred to as a *canonical ensemble*. The right-hand side of (1.539) contains the position operator \hat{x} in Cartesian coordinates rather than \hat{q} to ensure that the system can be quantized canonically. In cases such as the spinning top, the trace formula is also valid but the Hilbert space is spanned by the representation states of the angular momentum operators. In more general Lagrangian systems, the quantization has to be performed differently in the way to be described in Chapters 10 and 8.

At this point we make an important observation: The quantum partition function is related in a very simple way to the quantum-mechanical time evolution operator. To emphasize this relation we shall define the trace of this operator for time-independent Hamiltonians as the *quantum-mechanical partition function*:

$$Z_{\text{QM}}(t_b - t_a) \equiv \text{Tr} \left(\hat{U}(t_b, t_a) \right) = \text{Tr} \left(e^{-i(t_b - t_a)\hat{H}/\hbar} \right). \quad (1.540)$$

Obviously the quantum-statistical partition function $Z(T)$ may be obtained from the quantum-mechanical one by continuing the time interval $t_b - t_a$ to the negative imaginary value

$$t_b - t_a = -\frac{i\hbar}{k_B T} \equiv -i\hbar\beta. \quad (1.541)$$

This simple formal relation shows that the trace of the time evolution operator contains all information on the thermodynamic equilibrium properties of a quantum system.

1.17.2 Grand-Canonical Ensemble

For systems containing many bodies it is often convenient to study their equilibrium properties in contact with a particle reservoir characterized by a chemical potential μ . For this one defines what is called the *grand-canonical quantum-statistical partition function*

$$Z_G(T, \mu) = \text{Tr} \left(e^{-(\hat{H} - \mu\hat{N})/k_B T} \right). \quad (1.542)$$

Here \hat{N} is the operator counting the number of particles in each state of the ensemble. The combination of operators in the exponent,

$$\hat{H}_G = \hat{H} - \mu\hat{N}, \quad (1.543)$$

is called the *grand-canonical Hamiltonian*.

Given a partition function $Z(T)$ at a fixed particle number N , the *free energy* is defined by

$$F(T) = -k_B T \log Z(T). \quad (1.544)$$

Its grand-canonical version at a fixed chemical potential is

$$F_G(T, \mu) = -k_B T \log Z_G(T, \mu). \quad (1.545)$$

The *average energy* or *internal energy* is defined by

$$E = \text{Tr} \left(\hat{H} e^{-\hat{H}/k_B T} \right) / \text{Tr} \left(e^{-\hat{H}/k_B T} \right). \quad (1.546)$$

It may be obtained from the partition function $Z(T)$ by forming the temperature derivative

$$E = Z^{-1} k_B T^2 \frac{\partial}{\partial T} Z(T) = k_B T^2 \frac{\partial}{\partial T} \log Z(T). \quad (1.547)$$

In terms of the free energy (1.544), this becomes

$$E = T^2 \frac{\partial}{\partial T} (-F(T)/T) = \left(1 - T \frac{\partial}{\partial T} \right) F(T). \quad (1.548)$$

For a grand-canonical ensemble we may introduce an *average particle number* defined by

$$N = \text{Tr} \left(\hat{N} e^{-(\hat{H}-\mu\hat{N})/k_B T} \right) / \text{Tr} \left(e^{-(\hat{H}-\mu\hat{N})/k_B T} \right). \quad (1.549)$$

This can be derived from the grand-canonical partition function as

$$N = Z_G^{-1}(T, \mu) k_B T \frac{\partial}{\partial \mu} Z_G(T, \mu) = k_B T \frac{\partial}{\partial \mu} \log Z_G(T, \mu), \quad (1.550)$$

or, using the grand-canonical free energy, as

$$N = -\frac{\partial}{\partial \mu} F_G(T, \mu). \quad (1.551)$$

The average energy in a grand-canonical system,

$$E = \text{Tr} \left(\hat{H} e^{-(\hat{H}-\mu\hat{N})/k_B T} \right) / \text{Tr} \left(e^{-(\hat{H}-\mu\hat{N})/k_B T} \right), \quad (1.552)$$

can be obtained by forming, by analogy with (1.547) and (1.548), the derivative

$$\begin{aligned} E - \mu N &= Z_G^{-1}(T, \mu) k_B T^2 \frac{\partial}{\partial T} Z_G(T, \mu) \\ &= \left(1 - T \frac{\partial}{\partial T} \right) F_G(T, \mu). \end{aligned} \quad (1.553)$$

For a large number of particles, the density is a rapidly growing function of energy. For a system of N free particles, for example, the number of states up to energy E is given by

$$N(E) = \sum_{\mathbf{p}_i} \Theta(E - \sum_{i=1}^N \mathbf{p}_i^2 / 2M), \quad (1.554)$$

where each of the particle momenta \mathbf{p}_i is summed over all discrete momenta $\mathbf{p}^{\mathbf{m}}$ in (1.179) available to a single particle in a finite box of volume $V = L^3$. For a large V , the sum can be converted into an integral²⁶

$$N(E) = V^N \prod_{i=1}^N \left[\int \frac{d^3 p_i}{(2\pi\hbar)^3} \right] \Theta(E - \sum_{i=1}^N \mathbf{p}_i^2 / 2M), \quad (1.555)$$

²⁶Remember, however, the exception noted in the footnote to Eq. (1.184) for systems possessing a condensate.

which is simply $[V/(2\pi\hbar)^3]^N$ times the volume Ω_{3N} of a $3N$ -dimensional sphere of radius $\sqrt{2ME}$:

$$\begin{aligned} N(E) &= \left[\frac{V}{(2\pi\hbar)^3} \right]^N \Omega_{3N} \\ &\equiv \left[\frac{V}{(2\pi\hbar)^3} \right]^N \frac{(2\pi ME)^{3N/2}}{\Gamma\left(\frac{3}{2}N + 1\right)}. \end{aligned} \quad (1.556)$$

Recall the well-known formula for the volume of a unit sphere in D dimensions:

$$\Omega_D = \pi^{D/2} / \Gamma(D/2 + 1). \quad (1.557)$$

The surface is [see Eqs. (8.117) and (8.118) for a derivation]

$$S_D = 2\pi^{D/2} / \Gamma(D/2). \quad (1.558)$$

This follows directly from the integral²⁷

$$S_D = \int d^D p \delta(p-1) = \int d^D p 2\delta(p^2-1) = \int d^D p \int_{-\infty}^{\infty} \frac{d\lambda}{\pi} e^{i\lambda(p^2-1)} \quad (1.559)$$

$$= \int_{-\infty}^{\infty} \frac{d\lambda}{\pi} \left(\frac{\pi}{-i\lambda} \right)^{D/2} e^{-i\lambda} = \frac{2\pi^{D/2}}{\Gamma(D/2)} \quad (1.560)$$

Therefore, the density per energy $\rho = \partial N / \partial E$ is given by

$$\rho(E) = \left[\frac{V}{(2\pi\hbar)^3} \right]^N 2\pi M \frac{(2\pi ME)^{3N/2-1}}{\Gamma\left(\frac{3}{2}N\right)}. \quad (1.561)$$

It grows with the very large power $E^{3N/2}$ in the energy. Nevertheless, the integral for the partition function (1.582) is convergent, due to the overwhelming exponential falloff of the Boltzmann factor, $e^{-E/k_B T}$. As the two functions $\rho(e)$ and $e^{-e/k_B T}$ are multiplied with each other, the result is a function which peaks very sharply at the average energy E of the system. The position of the peak depends on the temperature T . For the free N particle system, for example,

$$\rho(E)e^{-E/k_B T} \sim e^{(3N/2-1)\log E - E/k_B T}. \quad (1.562)$$

This function has a sharp peak at

$$E(T) = k_B T \left(\frac{3N}{2} - 1 \right) \approx k_B T \frac{3N}{2}. \quad (1.563)$$

The width of the peak is found by expanding (1.562) in $\delta E = E - E(T)$:

$$\exp \left\{ \frac{3N}{2} \log E(T) - \frac{E(T)}{k_B T} - \frac{1}{2E^2(T)} \frac{3N}{2} (\delta E)^2 + \dots \right\}. \quad (1.564)$$

²⁷I. S. Gradshteyn and I. M. Ryzhik, op. cit., Formula 3.382.7.

Thus, as soon as δE gets to be of the order of $E(T)/\sqrt{N}$, the exponential is reduced by a factor of two with respect to $E(T) \approx k_B T \ln 2$. The deviation is of a relative order $1/\sqrt{N}$, i.e., the peak is very sharp. With N being very large, the peak at $E(T)$ of width $E(T)/\sqrt{N}$ can be idealized by a δ -function, and we may write

$$\rho(E)e^{-E/k_B T} \approx \delta(E - E(T))N(T)e^{-E(T)/k_B T}. \quad (1.565)$$

The quantity $N(T)$ measures the total number of states over which the system is distributed at the temperature T .

The entropy $S(T)$ is now defined in terms of $N(T)$ by

$$N(T) = e^{S(T)/k_B}. \quad (1.566)$$

Inserting this with (1.565) into (1.582), we see that in the limit of a large number of particles N :

$$Z(T) = e^{-[E(T) - TS(T)]/k_B T}. \quad (1.567)$$

Using (1.544), the free energy can thus be expressed in the form

$$F(T) = E(T) - TS(T). \quad (1.568)$$

By comparison with (1.548) we see that the entropy may be obtained from the free energy directly as

$$S(T) = -\frac{\partial}{\partial T} F(T). \quad (1.569)$$

For grand-canonical ensembles we may similarly consider

$$Z_G(T, \mu) = \int dE dn \rho(E, n) e^{-(E - \mu n)/k_B T}, \quad (1.570)$$

where

$$\rho(E, n) e^{-(E - \mu n)/k_B T} \quad (1.571)$$

is now strongly peaked at $E = E(T, \mu)$, $n = N(T, \mu)$ and can be written approximately as

$$\begin{aligned} \rho(E, n) e^{-(E - \mu n)/k_B T} &\approx \delta(E - E(T, \mu)) \delta(n - N(T, \mu)) \\ &\times e^{S(T, \mu)/k_B} e^{-[E(T, \mu) - \mu N(T, \mu)]/k_B T}. \end{aligned} \quad (1.572)$$

Inserting this back into (1.570) we find for large N

$$Z_G(T, \mu) = e^{-[E(T, \mu) - \mu N(T, \mu) - TS(T, \mu)]/k_B T}. \quad (1.573)$$

For the grand-canonical free energy (1.545), this implies the relation

$$F_G(T, \mu) = E(T, \mu) - \mu N(T, \mu) - TS(T, \mu). \quad (1.574)$$

By comparison with (1.553) we see that the entropy can be calculated directly from the derivative of the grand-canonical free energy

$$S(T, \mu) = -\frac{\partial}{\partial T} F_G(T, \mu). \quad (1.575)$$

The particle number is, of course, found from the derivative (1.551) with respect to the chemical potential, as follows directly from the definition (1.570).

The canonical free energy and the entropy appearing in the above equations depend on the particle number N and the volume V of the system, i.e., they are more explicitly written as $F(T, N, V)$ and $S(T, N, V)$, respectively.

In the arguments of the grand-canonical quantities, the particle number N is replaced by the chemical potential μ .

Among the arguments of the grand-canonical free energy $F_G(T, \mu, V)$, the volume V is the only one which grows with the system. Thus $F_G(T, \mu, V)$ must be directly proportional to V . The proportionality constant defines the *pressure* p of the system:

$$F_G(T, \mu, V) \equiv -p(T, \mu, V)V. \quad (1.576)$$

Under infinitesimal changes of the three variables, $F_G(T, \mu, V)$ changes as follows:

$$dF_G(T, \mu, V) = -SdT - Nd\mu - pdV. \quad (1.577)$$

The first two terms on the right-hand side follow from varying Eq. (1.574) at a fixed volume. When varying the volume, the definition (1.576) renders the last term.

Inserting (1.576) into (1.574), we find *Euler's relation*:

$$E = TS - Nd\mu - pV. \quad (1.578)$$

The energy has S, N, V as natural variables. Equivalently, we may write

$$F = -\mu N - pV, \quad (1.579)$$

where T, N, V are the natural variables.

1.18 Density of States and Tracelog

In many thermodynamic calculations, a quantity of fundamental interest is the density of states. To define it, we express the canonical partition function

$$Z(T) = \text{Tr} \left(e^{-\hat{H}/k_B T} \right) \quad (1.580)$$

as a sum over the Boltzmann factors of all eigenstates $|n\rangle$ of the Hamiltonian; i.e.

$$Z(T) = \sum_n e^{-E_n/k_B T}. \quad (1.581)$$

This can be rewritten as an integral:

$$Z(T) = \int dE \rho(E) e^{-E/k_B T}. \quad (1.582)$$

The quantity

$$\rho(E) = \sum_n \delta(E - E_n) \quad (1.583)$$

specifies the *density of states* of the system in the energy interval $(E, E + dE)$. It may also be written formally as a trace of the density of states operator $\hat{\rho}(E)$:

$$\rho(E) = \text{Tr } \hat{\rho}(E) \equiv \text{Tr } \delta(E - \hat{H}). \quad (1.584)$$

The density of states is obviously the Fourier transform of the canonical partition function (1.580):

$$\rho(E) = \int_{-i\infty}^{\infty} \frac{d\beta}{2\pi i} e^{\beta E} \text{Tr} (e^{-\beta \hat{H}}) = \int_{-i\infty}^{\infty} \frac{d\beta}{2\pi i} e^{\beta E} Z(1/k_B\beta). \quad (1.585)$$

The integral

$$N(E) = \int^E dE' \rho(E') \quad (1.586)$$

is the number of states up to energy E . The integration may start anywhere below the ground state energy. The function $N(E)$ is a sum of Heaviside step functions (1.313):

$$N(E) = \sum_n \Theta(E - E_n). \quad (1.587)$$

This equation is correct only with the Heaviside function which is equal to 1/2 at the origin, not with the one-sided version (1.306), as we shall see later. Indeed, if integrated to the energy of a certain level E_n , the result is

$$N(E_n) = (n + 1/2). \quad (1.588)$$

This formula will serve to determine the energies of bound states from approximations to $\omega(E)$ in Section 4.7, for instance from the Bohr-Sommerfeld condition (4.190) via the relation (4.210). In order to apply this relation one must be sure that all levels have different energies. Otherwise $N(E)$ jumps at E_n by half the degeneracy of this level. In Eq. (4A.9) we shall exhibit an example for this situation.

An important quantity related to $\rho(E)$ which will appear frequently in this text is the trace of the logarithm, short *tracelog*, of the operator $\hat{H} - E$.

$$\text{Tr } \log(\hat{H} - E) = \sum_n \log(E_n - E). \quad (1.589)$$

It may be expressed in terms of the density of states (1.584) as

$$\text{Tr } \log(\hat{H} - E) = \text{Tr} \int_{-\infty}^{\infty} dE' \delta(E' - \hat{H}) \log(E' - E) = \int_{-\infty}^{\infty} dE' \rho(E') \log(E' - E). \quad (1.590)$$

The tracelog of the Hamiltonian operator itself can be viewed as a limit of an *operator zeta function* associated with \hat{H} :

$$\hat{\zeta}_{\hat{H}}(\nu) = \text{Tr } \hat{H}^{-\nu}, \quad (1.591)$$

whose trace is the generalized zeta-function

$$\zeta_{\hat{H}}(\nu) \equiv \text{Tr} [\hat{\zeta}_{\hat{H}}(\nu)] = \text{Tr} (\hat{H}^{-\nu}) = \sum_n E_n^{-\nu}. \quad (1.592)$$

For a linearly spaced spectrum $E_n = n$ with $n = 1, 2, 3, \dots$, this reduces to Riemann's zeta function (2.521).

From the generalized zeta function we can obtain the tracelog by forming the derivative

$$\text{Tr} \log \hat{H} = -\partial_\nu \zeta_{\hat{H}}(\nu)|_{\nu=0}. \quad (1.593)$$

By differentiating the tracelog (1.589) with respect to E , we find the trace of the resolvent (1.319):

$$\partial_E \text{Tr} \log(\hat{H} - E) = \text{Tr} \frac{1}{E - \hat{H}} = \sum_n \frac{1}{E - E_n} = \frac{1}{i\hbar} \sum_n R_n(E) = \frac{1}{i\hbar} \text{Tr} \hat{R}(E). \quad (1.594)$$

Recalling Eq. (1.329) we see that the imaginary part of this quantity slightly above the real E -axis yields the density of states

$$-\frac{1}{\pi} \text{Im} \partial_E \text{Tr} \log(\hat{H} - E - i\eta) = \sum_n \delta(E - E_n) = \rho(E). \quad (1.595)$$

By integrating this over the energy we obtain the number of states function $N(E)$ of Eq. (1.586):

$$-\frac{1}{\pi} \text{Im} \text{Tr} \log(E - \hat{H}) = \sum_n \Theta(E - E_n) = N(E). \quad (1.596)$$

Appendix 1A Simple Time Evolution Operator

Consider the simplest nontrivial time evolution operator of a spin-1/2 particle in a magnetic field \mathbf{B} . The reduced Hamiltonian operator is $\hat{H}_0 = -\mathbf{B} \cdot \boldsymbol{\sigma}/2$, so that the time evolution operator reads, in natural units with $\hbar = 1$,

$$e^{-i\hat{H}_0(t_b - t_a)} = e^{i(t_b - t_a)\mathbf{B} \cdot \boldsymbol{\sigma}/2}. \quad (1A.1)$$

Expanding this as in (1.293) and using the fact that $(\mathbf{B} \cdot \boldsymbol{\sigma})^{2n} = B^{2n}$ and $(\mathbf{B} \cdot \boldsymbol{\sigma})^{2n+1} = B^{2n}(\mathbf{B} \cdot \boldsymbol{\sigma})$, we obtain

$$e^{-i\hat{H}_0(t_b - t_a)} = \cos[B(t_b - t_a)/2] + i\hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \sin[B(t_b - t_a)/2], \quad (1A.2)$$

where $\hat{\mathbf{B}} \equiv \mathbf{B}/|\mathbf{B}|$. Suppose now that the magnetic field is not constant but has a small time-dependent variation $\delta\mathbf{B}(t)$. Then we obtain from (1.253) [or the lowest expansion term in (1.293)]

$$\delta e^{-i\hat{H}_0(t_b - t_a)} = \int_{t_a}^{t_b} dt e^{-i\hat{H}_0(t_b - t)} \delta\mathbf{B}(t) \cdot \boldsymbol{\sigma} e^{-i\hat{H}_0(t - t_a)}. \quad (1A.3)$$

Using (1A.2), the integrand on the right-hand side becomes

$$\left\{ \cos[B(t_b - t)/2] + i\hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \sin[B(t_b - t)/2] \right\} \delta\mathbf{B}(t) \cdot \boldsymbol{\sigma} \left\{ \cos[B(t - t_a)/2] + i\hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \sin[B(t - t_a)/2] \right\}. \quad (1A.4)$$

We simplify this with the help of the formula [recall (1.448)]

$$\sigma^i \sigma^j = \delta_{ij} + i\epsilon_{ijk} \sigma^k \quad (1A.5)$$

so that

$$\hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \delta\mathbf{B}(t) \cdot \boldsymbol{\sigma} = \hat{\mathbf{B}} \cdot \delta\mathbf{B}(t) + i[\hat{\mathbf{B}} \times \delta\mathbf{B}(t)] \cdot \boldsymbol{\sigma}, \quad \delta\mathbf{B}(t) \cdot \boldsymbol{\sigma} \hat{\mathbf{B}} \cdot \boldsymbol{\sigma} = \hat{\mathbf{B}} \cdot \delta\mathbf{B}(t) - i[\hat{\mathbf{B}} \times \delta\mathbf{B}(t)] \cdot \boldsymbol{\sigma}, \quad (1A.6)$$

and

$$\begin{aligned}\hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \delta \mathbf{B}(t) \cdot \boldsymbol{\sigma} \hat{\mathbf{B}} \cdot \boldsymbol{\sigma} &= \left[\hat{\mathbf{B}} \cdot \delta \mathbf{B}(t) \right] \hat{\mathbf{B}} \cdot \boldsymbol{\sigma} + i \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \cdot \boldsymbol{\sigma} \hat{\mathbf{B}} \cdot \boldsymbol{\sigma} \\ &= i \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \cdot \hat{\mathbf{B}} + \left\{ \left[\hat{\mathbf{B}} \cdot \delta \mathbf{B}(t) \right] \hat{\mathbf{B}} - \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \times \hat{\mathbf{B}} \right\} \cdot \boldsymbol{\sigma}. \quad (1A.7)\end{aligned}$$

The first term on the right-hand side vanishes, the second term is equal to $\delta \mathbf{B}$, since $\hat{\mathbf{B}}^2 = 1$. Thus we find for the integrand in (1A.4):

$$\begin{aligned}& \cos B(t_b - t)/2 \cos B(t - t_a)/2 \delta \mathbf{B}(t) \cdot \boldsymbol{\sigma} \\ & + i \sin B(t_b - t)/2 \cos B(t - t_a)/2 \left\{ \hat{\mathbf{B}} \cdot \delta \mathbf{B}(t) + i \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \cdot \boldsymbol{\sigma} \right\} \\ & + i \cos B(t_b - t)/2 \sin B(t - t_a)/2 \left\{ \hat{\mathbf{B}} \cdot \delta \mathbf{B}(t) - i \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \cdot \boldsymbol{\sigma} \right\} \\ & + \sin B(t_b - t)/2 \sin B(t - t_a)/2 \delta \mathbf{B} \cdot \boldsymbol{\sigma} \quad (1A.8)\end{aligned}$$

which can be combined to give

$$\left\{ \cos B[(t_b + t_a)/2 - t] \delta \mathbf{B}(t) - \sin B[(t_b + t_a)/2 - t] \left[\hat{\mathbf{B}} \times \delta \mathbf{B}(t) \right] \right\} \cdot \boldsymbol{\sigma} + i \sin[B(t_b - t_a)/2] \hat{\mathbf{B}} \cdot \delta \mathbf{B}(t). \quad (1A.9)$$

Integrating this from t_a to t_b we obtain the variation (1A.3).

Appendix 1B Convergence of the Fresnel Integral

Here we prove the convergence of the Fresnel integral (1.337) by relating it to the Gauss integral. According to Cauchy's integral theorem, the sum of the integrals along the three pieces of the

Figure 1.4 Triangular closed contour for Cauchy integral

closed contour shown in Fig. 1.4 vanishes since the integrand e^{-z^2} is analytic in the triangular domain:

$$\oint dz e^{-z^2} = \int_0^A dz e^{-z^2} + \int_A^B dz e^{-z^2} + \int_B^O dz e^{-z^2} = 0. \quad (1B.1)$$

Let R be the radius of the arc. Then we substitute in the three integrals the variable z as follows:

$$\begin{aligned}0A: & z = p, & dz &= dp, & z^2 &= p^2 \\ B0: & z = p e^{i\pi/4}, & dz &= dp e^{i\pi/4}, & z^2 &= ip^2 \\ AB: & z = R e^{i\varphi}, & dz &= i R d\varphi, & z^2 &= p^2,\end{aligned}$$

and obtain the equation

$$\int_0^R dp e^{-p^2} + e^{i\pi/4} \int_R^0 dp e^{-ip^2} + \int_0^{\pi/4} d\varphi i R e^{-R^2(\cos 2\varphi + i \sin 2\varphi) + i\varphi} = 0. \quad (1B.2)$$

The first integral converges rapidly to $\sqrt{\pi}/2$ for $R \rightarrow \infty$. The last term goes to zero in this limit. To see this we estimate its absolute value as follows:

$$\left| \int_0^{\pi/4} d\varphi i R e^{-R^2(\cos 2\varphi + i \sin 2\varphi) + i\varphi} \right| < R \int_0^{\pi/4} d\varphi e^{-R^2 \cos 2\varphi}. \quad (1B.3)$$

The right-hand side goes to zero exponentially fast, except for angles φ close to $\pi/4$ where the cosine in the exponent vanishes. In the dangerous regime $\alpha \in (\pi/4 - \epsilon, \pi/4)$ with small $\epsilon > 0$, one certainly has $\sin 2\varphi > \sin 2\alpha$, so that

$$R \int_{\alpha}^{\pi/4} d\varphi e^{-R^2 \cos 2\varphi} < R \int_{\alpha}^{\pi/4} d\varphi \frac{\sin 2\varphi}{\sin 2\alpha} e^{-R^2 \cos 2\varphi}. \quad (1B.4)$$

The right-hand integral can be performed by parts and yields

$$\alpha R e^{-R^2 \cos 2\alpha} + \frac{1}{R \sin 2\alpha} \left[e^{-R^2 \cos 2\varphi} \right]_{\varphi=\alpha}^{\varphi=\pi/4}, \quad (1B.5)$$

which goes to zero like $1/R$ for large R . Thus we find from (1B.2) the limiting formula $\int_{\infty}^0 dp e^{-ip^2} = -e^{-i\pi/4} \sqrt{\pi}/2$, or

$$\int_{\infty}^0 dp e^{-ip^2} = e^{-i\pi/4} \sqrt{\pi}, \quad (1B.6)$$

which goes into Fresnel's integral formula (1.337) by substituting $p \rightarrow p\sqrt{a/2}$.

Appendix 1C The Asymmetric Top

The Lagrangian of the asymmetric top with three different moments of inertia reads

$$L = \frac{1}{2} [I_{\xi} \omega_{\xi}^2 + I_{\eta} \omega_{\eta}^2 + I_{\zeta} \omega_{\zeta}^2]. \quad (1C.1)$$

It has the Hessian metric [recall (1.12) and (1.388)]

$$\begin{aligned} g_{11} &= I_{\xi} \sin^2 \beta + I_{\zeta} \cos^2 \beta - (I_{\xi} - I_{\eta}) \sin^2 \beta \sin^2 \gamma, \\ g_{21} &= -(I_{\xi} - I_{\eta}) \sin \beta \sin \gamma \cos \gamma, \\ g_{31} &= I_{\zeta} \cos \beta, \\ g_{22} &= I_{\eta} + (I_{\xi} - I_{\eta}) \sin^2 \gamma, \\ g_{32} &= 0, \\ g_{33} &= I_{\zeta}, \end{aligned} \quad (1C.2)$$

rather than (1.462). The determinant is

$$g = I_{\xi} I_{\eta} I_{\zeta} \sin^2 \beta, \quad (1C.3)$$

and the inverse metric has the components

$$\begin{aligned} g^{11} &= \frac{1}{g} \{ I_{\eta} + (I_{\xi} - I_{\eta}) \sin^2 \gamma \} I_{\zeta}, \\ g^{21} &= \frac{1}{g} \sin \beta \sin \gamma \cos \gamma (I_{\xi} - I_{\eta}) I_{\zeta}, \\ g^{31} &= \frac{1}{g} \{ \cos \beta [-\sin^2 \gamma (I_{\xi} - I_{\eta}) - I_{\eta}] \} I_{\zeta}, \\ g^{22} &= \frac{1}{g} \{ \sin^2 \beta [I_{\xi} - \sin^2 \gamma (I_{\xi} - I_{\eta})] \} I_{\zeta}, \\ g^{32} &= \frac{1}{g} \{ \sin \beta \cos \beta \sin \gamma \cos \gamma (I_{\eta} - I_{\xi}) \} I_{\zeta}, \\ g^{33} &= \frac{1}{g} \{ \sin^2 \beta I_{\xi} I_{\eta} + \cos^2 \beta I_{\eta} I_{\zeta} + \cos^2 \beta \sin^2 \gamma (I_{\xi} - I_{\eta}) I_{\zeta} \}. \end{aligned} \quad (1C.4)$$

From this we find the components of the Riemann connection, the Christoffel symbol defined in Eq. (1.70):

$$\begin{aligned}
\bar{\Gamma}_{11}^1 &= [\cos \beta \cos \gamma \sin \gamma (I_\eta^2 - I_\eta I_\zeta - I_\xi^2 + I_\xi I_\zeta)] / I_\xi I_\eta, \\
\bar{\Gamma}_{21}^1 &= \{\cos \beta [\sin^2 \gamma (I_\xi^2 - I_\eta^2 - (I_\xi - I_\eta) I_\zeta) \\
&\quad + I_\eta (I_\xi + I_\eta - I_\zeta)]\} / 2 \sin \beta I_\xi I_\eta, \\
\bar{\Gamma}_{31}^1 &= \{\cos \gamma \sin \gamma [I_\eta^2 - I_\xi^2 + (I_\xi - I_\eta) I_\zeta]\} / 2 I_\xi I_\eta, \\
\bar{\Gamma}_{22}^1 &= 0, \\
\bar{\Gamma}_{32}^1 &= [\sin^2 \gamma (I_\xi^2 - I_\eta^2 - (I_\xi - I_\eta) I_\zeta) - I_\eta (I_\xi - I_\eta + I_\zeta)] / 2 \sin \beta I_\xi I_\eta, \\
\bar{\Gamma}_{33}^1 &= 0, \\
\bar{\Gamma}_{11}^2 &= \{\cos \beta \sin \beta [\sin^2 \gamma (I_\xi^2 - I_\eta^2 - I_\zeta (I_\xi - I_\eta)) - I_\xi (I_\xi - I_\zeta)]\} / I_\xi I_\eta, \\
\bar{\Gamma}_{21}^2 &= \{\cos \beta \cos \gamma \sin \gamma [I_\xi^2 - I_\eta^2 - I_\zeta (I_\xi - I_\eta)]\} / 2 I_\xi I_\eta, \\
\bar{\Gamma}_{31}^2 &= \{\sin \beta [\sin^2 \gamma (I_\xi^2 - I_\eta^2 - I_\zeta (I_\xi - I_\eta)) - I_\xi (I_\xi - I_\eta - I_\zeta)]\} / 2 I_\xi I_\eta, \\
\bar{\Gamma}_{22}^2 &= 0, \\
\bar{\Gamma}_{32}^2 &= [\cos \gamma \sin \gamma (I_\xi^2 - I_\eta^2 - I_\zeta (I_\xi - I_\eta))] / 2 I_\xi I_\eta, \\
\bar{\Gamma}_{33}^2 &= 0, \\
\bar{\Gamma}_{11}^3 &= \{\cos \gamma \sin \gamma [\sin^2 \beta (I_\xi I_\eta (I_\xi - I_\eta) - I_\zeta (I_\xi^2 - I_\eta^2) + I_\zeta^2 (I_\xi - I_\eta)) \\
&\quad + (I_\xi^2 - I_\eta^2) I_\zeta - I_\zeta^2 (I_\xi - I_\eta)]\} / I_\xi I_\eta I_\zeta, \\
\bar{\Gamma}_{21}^3 &= \{\sin^2 \beta [\sin^2 \gamma (2 I_\xi I_\eta (I_\eta - I_\xi) + I_\zeta (I_\xi^2 - I_\eta^2) - I_\zeta^2 (I_\xi - I_\eta)) \\
&\quad + I_\xi I_\eta (I_\xi - I_\eta) + I_\eta I_\zeta (I_\eta - I_\zeta)] - \sin^2 \gamma ((I_\xi^2 - I_\eta^2) I_\zeta - I_\zeta^2 (I_\xi - I_\eta)) \\
&\quad - I_\eta I_\zeta (I_\xi + I_\eta - I_\zeta)\} / 2 \sin \beta I_\xi I_\eta I_\zeta, \\
\bar{\Gamma}_{31}^3 &= [\cos \beta \cos \gamma \sin \gamma (I_\xi^2 - I_\eta^2 - I_\zeta (I_\xi - I_\eta))] / 2 I_\xi I_\eta, \\
\bar{\Gamma}_{22}^3 &= \cos \gamma \sin \gamma (I_\eta - I_\xi) / I_\zeta, \\
\bar{\Gamma}_{32}^3 &= \{\cos \beta [\sin^2 \gamma (I_\eta^2 - I_\xi^2 + (I_\xi - I_\eta) I_\zeta) + I_\eta (I_\xi - I_\eta + I_\zeta)]\} / 2 \sin \beta I_\eta I_\xi, \\
\bar{\Gamma}_{33}^3 &= 0.
\end{aligned} \tag{1C.5}$$

The other components follow from the symmetry in the first two indices $\bar{\Gamma}_{\mu\nu}^\lambda = \bar{\Gamma}_{\nu\mu}^\lambda$. From this Christoffel symbol we calculate the Ricci tensor, to be defined in Eq. (10.41),

$$\begin{aligned}
\bar{R}_{11} &= \{\sin^2 \beta [\sin^2 \gamma (I_\eta^3 - I_\xi^3 - (I_\xi I_\eta - I_\zeta^2) (I_\xi - I_\eta)) \\
&\quad + ((I_\xi + I_\zeta)^2 - I_\eta^2) (I_\xi - I_\zeta)] + I_\zeta^3 - I_\zeta (I_\xi - I_\eta)^2\} / 2 I_\xi I_\eta I_\zeta, \\
\bar{R}_{21} &= \{\sin \beta \sin \gamma \cos \gamma [I_\eta^3 - I_\xi^3 + (I_\xi I_\eta - I_\zeta^2) (I_\eta - I_\xi)]\} / 2 I_\xi I_\eta I_\zeta, \\
\bar{R}_{31} &= -\{\cos \beta [(I_\xi - I_\eta)^2 - I_\zeta^2]\} / 2 I_\xi I_\eta, \\
\bar{R}_{22} &= \{\sin^2 \gamma [I_\xi^3 - I_\eta^3 + (I_\xi I_\eta - I_\zeta^2) (I_\xi - I_\eta)] + I_\eta^3 - (I_\xi - I_\zeta)^2 I_\eta\} / 2 I_\xi I_\eta I_\zeta, \\
\bar{R}_{32} &= 0, \\
\bar{R}_{33} &= -[(I_\xi - I_\eta)^2 - I_\zeta^2] / 2 I_\xi I_\eta.
\end{aligned} \tag{1C.6}$$

Contraction with $g^{\mu\nu}$ gives the curvature scalar

$$\bar{R} = [2(I_\xi I_\eta + I_\eta I_\zeta + I_\zeta I_\xi) - I_\xi^2 - I_\eta^2 - I_\zeta^2] / 2 I_\xi I_\eta I_\zeta. \tag{1C.7}$$

Since the space under consideration is free of torsion, the Christoffel symbol $\bar{\Gamma}_{\mu\nu}^\lambda$ is equal to the full affine connection $\Gamma_{\mu\nu}^\lambda$. The same thing is true for the curvature scalars \bar{R} and R calculated from $\bar{\Gamma}_{\mu\nu}^\lambda$ and $\Gamma_{\mu\nu}^\lambda$, respectively.

2

Path Integrals — Elementary Properties and Simple Solutions

The operator formalism of quantum mechanics and quantum statistics may not always lead to the most transparent understanding of quantum phenomena. There exists another, equivalent formalism in which operators are avoided by the use of infinite products of integrals, called *path integrals*. In contrast to the Schrödinger equation, which is a differential equation determining the properties of a state at a time from their knowledge at an infinitesimally earlier time, path integrals yield the quantum-mechanical amplitudes in a global approach involving the properties of a system at *all times*.

2.1 Path Integral Representation of Time Evolution Amplitudes

The path integral approach to quantum mechanics was developed by Feynman¹ in 1942. In its original form, it applies to a point particle moving in a Cartesian coordinate system and yields the transition amplitudes of the time evolution operator between the localized states of the particle (recall Section 1.7)

$$\langle x_b t_b | x_a t_a \rangle = \langle x_b | \hat{U}(t_b, t_a) | x_a \rangle, \quad t_b > t_a. \quad (2.1)$$

For simplicity, we shall at first assume the space to be one-dimensional. The extension to D Cartesian dimensions will be given later. The introduction of curvilinear coordinates will require a little more work. A further generalization to spaces with a nontrivial geometry, in which curvature and torsion are present, will be described in Chapters 10–11.

2.1.1 Sliced Time Evolution Amplitude

We shall be interested mainly in the causal or retarded time evolution amplitudes [see Eq. (1.303)]. These contain all relevant quantum-mechanical information and

¹For the historical development, see Notes and References at the end of this chapter.

possess, in addition, pleasant analytic properties in the complex energy plane [see the remarks after Eq. (1.310)]. This is why we shall always assume, from now on, the causal sequence of time arguments $t_b > t_a$.

Feynman realized that due to the fundamental composition law of the time evolution operator (see Section 1.7), the amplitude (2.1) could be sliced into a large number, say $N + 1$, of time evolution operators, each acting across an infinitesimal time slice of thickness $\epsilon \equiv t_n - t_{n-1} = (t_b - t_a)/(N + 1) > 0$:

$$\langle x_b t_b | x_a t_a \rangle = \langle x_b | \hat{U}(t_b, t_N) \hat{U}(t_N, t_{N-1}) \cdots \hat{U}(t_n, t_{n-1}) \cdots \hat{U}(t_2, t_1) \hat{U}(t_1, t_a) | x_a \rangle. \quad (2.2)$$

When inserting a complete set of states between each pair of \hat{U} 's,

$$\int_{-\infty}^{\infty} dx_n |x_n\rangle \langle x_n| = 1, \quad n = 1, \dots, N, \quad (2.3)$$

the amplitude becomes a product of N -integrals

$$\langle x_b t_b | x_a t_a \rangle = \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \langle x_n t_n | x_{n-1} t_{n-1} \rangle, \quad (2.4)$$

where we have set $x_b \equiv x_{N+1}$, $x_a \equiv x_0$, $t_b \equiv t_{N+1}$, $t_a \equiv t_0$. The symbol $\Pi[\dots]$ denotes the product of the quantities within the brackets. The integrand is the product of the amplitudes for the infinitesimal time intervals

$$\langle x_n t_n | x_{n-1} t_{n-1} \rangle = \langle x_n | e^{-i\epsilon \hat{H}(t_n)/\hbar} | x_{n-1} \rangle, \quad (2.5)$$

with the Hamiltonian operator

$$\hat{H}(t) \equiv H(\hat{p}, \hat{x}, t). \quad (2.6)$$

The further development becomes simplest under the assumption that the Hamiltonian has the standard form, being the sum of a kinetic and a potential energy:

$$H(p, x, t) = T(p, t) + V(x, t). \quad (2.7)$$

For a sufficiently small slice thickness, the time evolution operator

$$e^{-i\epsilon \hat{H}/\hbar} = e^{-i\epsilon(\hat{T} + \hat{V})/\hbar} \quad (2.8)$$

is factorizable as a consequence of the *Baker-Campbell-Hausdorff formula* (to be proved in Appendix 2A)

$$e^{-i\epsilon(\hat{T} + \hat{V})/\hbar} = e^{-i\epsilon \hat{V}/\hbar} e^{-i\epsilon \hat{T}/\hbar} e^{-i\epsilon^2 \hat{X}/\hbar^2}, \quad (2.9)$$

where the operator \hat{X} has the expansion

$$\hat{X} \equiv \frac{i}{2} [\hat{V}, \hat{T}] - \frac{\epsilon}{\hbar} \left(\frac{1}{6} [\hat{V}, [\hat{V}, \hat{T}]] - \frac{1}{3} [[\hat{V}, \hat{T}], \hat{T}] \right) + \mathcal{O}(\epsilon^2). \quad (2.10)$$

The omitted terms of order $\epsilon^4, \epsilon^5, \dots$ contain higher commutators of \hat{V} and \hat{T} . If we neglect, for the moment, the \hat{X} -term which is suppressed by a factor ϵ^2 , we calculate for the local matrix elements of $e^{-i\epsilon\hat{H}/\hbar}$ the following simple expression:

$$\begin{aligned} \langle x_n | e^{-i\epsilon H(\hat{p}, \hat{x}, t_n)/\hbar} | x_{n-1} \rangle &\approx \int_{-\infty}^{\infty} dx \langle x_n | e^{-i\epsilon V(\hat{x}, t_n)/\hbar} | x \rangle \langle x | e^{-i\epsilon T(\hat{p}, t_n)/\hbar} | x_{n-1} \rangle \\ &= \int_{-\infty}^{\infty} dx \langle x_n | e^{-i\epsilon V(\hat{x}, t_n)/\hbar} | x \rangle \int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} e^{ip_n(x-x_{n-1})/\hbar} e^{-i\epsilon T(p_n, t_n)/\hbar}. \end{aligned} \quad (2.11)$$

Evaluating the local matrix elements,

$$\langle x_n | e^{-i\epsilon V(\hat{x}, t_n)/\hbar} | x \rangle = \delta(x_n - x) e^{-i\epsilon V(x_n, t_n)/\hbar}, \quad (2.12)$$

this becomes

$$\begin{aligned} \langle x_n | e^{-i\epsilon H(\hat{p}, \hat{x}, t_n)/\hbar} | x_{n-1} \rangle &\approx \\ &\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \exp \{ ip_n(x_n - x_{n-1})/\hbar - i\epsilon [T(p_n, t_n) + V(x_n, t_n)]/\hbar \}. \end{aligned} \quad (2.13)$$

Inserting this back into (2.4), we obtain *Feynman's path integral formula*, consisting of the multiple integral

$$(x_b t_b | x_a t_a) \approx \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \exp \left(\frac{i}{\hbar} \mathcal{A}^N \right), \quad (2.14)$$

where \mathcal{A}^N is the sum

$$\mathcal{A}^N = \sum_{n=1}^{N+1} [p_n(x_n - x_{n-1}) - \epsilon H(p_n, x_n, t_n)]. \quad (2.15)$$

2.1.2 Zero-Hamiltonian Path Integral

Note that the path integral (2.14) with zero Hamiltonian produces the Hilbert space structure of the theory via a chain of scalar products:

$$(x_b t_b | x_a t_a) \approx \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] e^{i \sum_{n=1}^{N+1} p_n(x_n - x_{n-1})/\hbar}, \quad (2.16)$$

which is equal to

$$\begin{aligned} (x_b t_b | x_a t_a) &\approx \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \langle x_n | x_{n-1} \rangle = \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \delta(x_n - x_{n-1}) \\ &= \delta(x_b - x_a). \end{aligned} \quad (2.17)$$

whose continuum limit is

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{i \int dt p(t) \dot{x}(t)/\hbar} = \langle x_b | x_a \rangle = \delta(x_b - x_a). \quad (2.18)$$

In the operator expression (2.2), the right-hand side follows from the fact that for zero Hamiltonian the time evolution operators $\hat{U}(t_n, t_{n-1})$ are all equal to unity.

At this point we make the important observation that a momentum variable p_n *inside* the product of momenta integrations in the expression (2.16) can be generated by a derivative $\hat{p}_n \equiv -i\hbar\partial_{x_n}$ *outside* of it. In Subsection 2.1.4 we shall go to the *continuum limit* of time slicing in which the slice thickness ϵ goes to zero. In this limit, the discrete variables x_n and p_n become functions $x(t)$ and $p(t)$ of the continuous time t , and the momenta p_n become differential operators $p(t) = -i\hbar\partial_{x(t)}$, satisfying the commutation relations with $x(t)$:

$$[\hat{p}(t), x(t)] = -i\hbar. \quad (2.19)$$

These are the canonical *equal-time commutation relations* of Heisenberg.

This observation forms the basis for deriving, from the path integral (2.14), the Schrödinger equation for the time evolution amplitude.

2.1.3 Schrödinger Equation for Time Evolution Amplitude

Let us split from the product of integrals in (2.14) the final time slice as a factor, so that we obtain the recursion relation

$$(x_b t_b | x_a t_a) \approx \int_{-\infty}^{\infty} dx_N (x_b t_b | x_N t_N) (x_N t_N | x_a t_a), \quad (2.20)$$

where

$$(x_b t_b | x_N t_N) \approx \int_{-\infty}^{\infty} \frac{dp_b}{2\pi\hbar} e^{(i/\hbar)[p_b(x_b - x_N) - \epsilon H(p_b, x_b, t_b)]}. \quad (2.21)$$

The momentum p_b *inside* the integral can be generated by a differential operator $\hat{p}_b \equiv -i\hbar\partial_{x_b}$ *outside* of it. The same is true for any function of p_b , so that the Hamiltonian can be moved before the momentum integral yielding

$$(x_b t_b | x_N t_N) \approx e^{-i\epsilon H(-i\hbar\partial_{x_b}, x_b, t_b)/\hbar} \int_{-\infty}^{\infty} \frac{dp_b}{2\pi\hbar} e^{ip_b(x_b - x_N)/\hbar} = e^{-i\epsilon H(-i\hbar\partial_{x_b}, x_b, t_b)/\hbar} \delta(x_b - x_N). \quad (2.22)$$

Inserting this back into (2.20) we obtain

$$(x_b t_b | x_a t_a) \approx e^{-i\epsilon H(-i\hbar\partial_{x_b}, x_b, t_b)/\hbar} (x_b t_b - \epsilon | x_a t_a), \quad (2.23)$$

or

$$\frac{1}{\epsilon} [(x_b t_b + \epsilon | x_a t_a) - (x_b t_b | x_a t_a)] \approx \frac{1}{\epsilon} [e^{-i\epsilon H(-i\hbar\partial_{x_b}, x_b, t_b + \epsilon)/\hbar} - 1] (x_b t_b | x_a t_a). \quad (2.24)$$

In the limit $\epsilon \rightarrow 0$, this goes over into the differential equation for the time evolution amplitude

$$i\hbar\partial_{t_b} (x_b t_b | x_a t_a) = H(-i\hbar\partial_{x_b}, x_b, t_b) (x_b t_b | x_a t_a), \quad (2.25)$$

which is precisely the Schrödinger equation (1.301) of operator quantum mechanics.

2.1.4 Convergence of of the Time-Sliced Evolution Amplitude

Some remarks are necessary concerning the convergence of the time-sliced expression (2.14) to the quantum-mechanical amplitude in the continuum limit, where the thickness of the time slices $\epsilon = (t_b - t_a)/(N + 1) \rightarrow 0$ goes to zero and the number N of slices tends to ∞ . This convergence can be proved for the standard kinetic energy $T = p^2/2M$ only if the potential $V(x, t)$ is sufficiently *smooth*. For time-independent potentials this is a consequence of the *Trotter product formula* which reads

$$e^{-i(t_b-t_a)\hat{H}/\hbar} = \lim_{N \rightarrow \infty} \left(e^{-i\epsilon\hat{V}/\hbar} e^{-i\epsilon\hat{T}/\hbar} \right)^{N+1}. \quad (2.26)$$

If T and V are c -numbers, this is trivially true. If they are operators, we use Eq. (2.9) to rewrite the left-hand side of (2.26) as

$$e^{-i(t_b-t_a)\hat{H}/\hbar} \equiv \left(e^{-i\epsilon(\hat{T}+\hat{V})/\hbar} \right)^{N+1} \equiv \left(e^{-i\epsilon\hat{V}/\hbar} e^{-i\epsilon\hat{T}/\hbar} e^{-i\epsilon^2\hat{X}/\hbar^2} \right)^{N+1}.$$

The Trotter formula implies that the commutator term \hat{X} proportional to ϵ^2 does not contribute in the limit $N \rightarrow \infty$. The mathematical conditions ensuring this require functional analysis too technical to be presented here (for details, see the literature quoted at the end of the chapter). For us it is sufficient to know that the Trotter formula holds for operators which are bounded from below and that for most physically interesting potentials, it cannot be used to derive Feynman's time-sliced path integral representation (2.14), even in systems where the formula is known to be valid. In particular, the short-time amplitude may be different from (2.13). Take, for example, an attractive Coulomb potential $V(x) \propto -1/|x|$ for which the Trotter formula has been proved to be valid. Feynman's time-sliced formula, however, diverges even for two time slices. This will be discussed in detail in Chapter 12. Similar problems will be found for other physically relevant potentials such as $V(x) \propto l(l + D - 2)\hbar^2/|x|^2$ (centrifugal barrier) and $V(\theta) \propto m^2\hbar^2/\sin^2\theta$ (angular barrier near the poles of a sphere). In all these cases, the commutators in the expansion (2.10) of \hat{X} become more and more singular. In fact, as we shall see, the expansion does not even converge, even for an infinitesimally small ϵ . All atomic systems contain such potentials and the Feynman formula (2.14) cannot be used to calculate an approximation for the transition amplitude. A new path integral formula has to be found. This will be done in Chapter 12. Fortunately, it is possible to eventually reduce the more general formula via some transformations back to a Feynman type formula with a bounded potential in an auxiliary space. Thus the above derivation of Feynman's formula for such potentials will be sufficient for the further development in this book. After this it serves as an *independent* starting point for all further quantum-mechanical calculations.

In the sequel, the symbol \approx in all time-sliced formulas such as (2.14) will imply that an equality emerges in the *continuum limit* $N \rightarrow \infty$, $\epsilon \rightarrow 0$ unless the potential

has singularities of the above type. In the action, the continuum limit is without subtleties. The sum \mathcal{A}^N in (2.15) tends towards the integral

$$\mathcal{A}[p, x] = \int_{t_a}^{t_b} dt [p(t)\dot{x}(t) - H(p(t), x(t), t)] \quad (2.27)$$

under quite general circumstances. This expression is recognized as the classical canonical action for the path $x(t), p(t)$ in phase space. Since the position variables x_{N+1} and x_0 are fixed at their initial and final values x_b and x_a , the paths satisfy the boundary condition $x(t_b) = x_b$, $x(t_a) = x_a$.

In the same limit, the product of infinitely many integrals in (2.14) will be called a *path integral*. The limiting measure of integration is written as

$$\lim_{N \rightarrow \infty} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \equiv \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar}. \quad (2.28)$$

By definition, there is always one more p_n -integral than x_n -integrals in this product. While x_0 and x_{N+1} are held fixed and the x_n -integrals are done for $n = 1, \dots, N$, each pair (x_n, x_{n-1}) is accompanied by one p_n -integral for $n = 1, \dots, N+1$. The situation is recorded by the prime on the functional integral $\mathcal{D}'x$. With this definition, the amplitude can be written in the short form

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{i\mathcal{A}[p,x]/\hbar}. \quad (2.29)$$

The path integral has a simple intuitive interpretation: Integrating over all paths corresponds to summing over all histories along which a physical system can possibly evolve. The exponential $e^{i\mathcal{A}[p,x]/\hbar}$ is the quantum analog of the Boltzmann factor $e^{-E/k_B T}$ in statistical mechanics. Instead of an exponential probability, a pure phase factor is assigned to each possible history: The total amplitude for going from x_a, t_a to x_b, t_b is obtained by adding up the phase factors for all these histories,

$$(x_b t_b | x_a t_a) = \sum_{\substack{\text{all histories} \\ (x_a, t_a) \sim (x_b, t_b)}} e^{i\mathcal{A}[p,x]/\hbar}, \quad (2.30)$$

where the sum comprises all paths in phase space with fixed endpoints x_b, x_a in x -space.

2.1.5 Time Evolution Amplitude in Momentum Space

The above observed asymmetry in the functional integrals over x and p is a consequence of keeping the endpoints fixed in *position space*. There exists the possibility of proceeding in a conjugate way keeping the initial and final *momenta* p_b and p_a fixed. The associated time evolution amplitude can be derived by going through the same steps as before but working in the momentum space representation of the Hilbert space, starting from the matrix elements of the time evolution operator

$$(p_b t_b | p_a t_a) \equiv \langle p_b | \hat{U}(t_b, t_a) | p_a \rangle. \quad (2.31)$$

The time slicing proceeds as in (2.2)–(2.4), with all x 's replaced by p 's, except in the completeness relation (2.3) which we shall take as

$$\int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} |p\rangle\langle p| = 1, \quad (2.32)$$

corresponding to the choice of the normalization of states [compare (1.186)]

$$\langle p_b | p_a \rangle = 2\pi\hbar\delta(p_b - p_a). \quad (2.33)$$

In the resulting product of integrals, the integration measure has an opposite asymmetry: there is now one more x_n -integral than p_n -integrals. The sliced path integral reads

$$\begin{aligned} (p_b t_b | p_a t_a) &\approx \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \prod_{n=0}^N \left[\int_{-\infty}^{\infty} dx_n \right] \\ &\times \exp \left\{ \frac{i}{\hbar} \sum_{n=0}^N [-x_n(p_{n+1} - p_n) - \epsilon H(p_n, x_n, t_n)] \right\}. \end{aligned} \quad (2.34)$$

The relation between this and the x -space amplitude (2.14) is simple: By taking in (2.14) the first and last integrals over p_1 and p_{N+1} out of the product, renaming them as p_a and p_b , and rearranging the sum $\sum_{n=1}^{N+1} p_n(x_n - x_{n-1})$ as follows

$$\begin{aligned} \sum_{n=1}^{N+1} p_n(x_n - x_{n-1}) &= p_{N+1}(x_{N+1} - x_N) + p_N(x_N - x_{N-1}) + \dots \\ &\quad \dots + p_2(x_2 - x_1) + p_1(x_1 - x_0) \\ &= p_{N+1}x_{N+1} - p_1x_0 \\ &\quad - (p_{N+1} - p_N)x_N - (p_N - p_{N-1})x_{N-1} - \dots - (p_2 - p_1)x_1 \\ &= p_{N+1}x_{N+1} - p_1x_0 - \sum_{n=1}^N (p_{n+1} - p_n)x_n, \end{aligned} \quad (2.35)$$

the remaining product of integrals looks as in Eq. (2.34), except that the lowest index n is one unit larger than in the sum in Eq. (2.34). In the limit $N \rightarrow \infty$ this does not matter, and we obtain the Fourier transform

$$(x_b t_b | x_a t_a) = \int \frac{dp_b}{2\pi\hbar} e^{ip_b x_b / \hbar} \int \frac{dp_a}{2\pi\hbar} e^{-ip_a x_a / \hbar} (p_b t_b | p_a t_a). \quad (2.36)$$

The inverse relation is

$$(p_b t_b | p_a t_a) = \int dx_b e^{-ip_b x_b / \hbar} \int dx_a e^{ip_a x_a / \hbar} (x_b t_b | x_a t_a). \quad (2.37)$$

In the continuum limit, the amplitude (2.34) can be written as a path integral

$$(p_b t_b | p_a t_a) = \int_{p(t_a)=p_a}^{p(t_b)=p_b} \frac{\mathcal{D}'p}{2\pi\hbar} \int \mathcal{D}x e^{i\bar{\mathcal{A}}[p,x]/\hbar}, \quad (2.38)$$

where

$$\bar{\mathcal{A}}[p, x] = \int_{t_a}^{t_b} dt [-\dot{p}(t)x(t) - H(p(t), x(t), t)] = \mathcal{A}[p, x] - p_b x_b + p_a x_a. \quad (2.39)$$

If the Hamiltonian is independent of x and t , the sliced path integral (2.34) becomes trivial. Then the $N + 1$ integrals over x_n ($n = 0, \dots, N$) can be done yielding a product of δ -functions $\delta(p_b - p_N) \cdots \delta(p_1 - p_0)$. As a consequence, the integrals over the N momenta p_n ($n = 1, \dots, N$) are all squeezed to the initial momentum $p_N = p_{N-1} = \dots = p_1 = p_a$. A single a final δ -function $2\pi\hbar\delta(p_b - p_a)$ remains, accompanied by the product of $N + 1$ factors $\prod_{n=0}^N e^{-i\epsilon H(p_a)/\hbar}$, which is equal to $e^{-i(t_b-t_a)H(p)/\hbar}$. Hence we obtain:

$$(p_b t_b | p_a t_a) = 2\pi\hbar\delta(p_b - p_a)e^{-i(t_b-t_a)H(p)/\hbar}. \quad (2.40)$$

Inserting this into Eq. (2.36), we find a simple Fourier integral for the time evolution amplitude in x -space:

$$(x_b t_b | x_a t_a) = \int \frac{dp}{2\pi\hbar} e^{ip(x_b-x_a)/\hbar - i(t_b-t_a)H(p)/\hbar}. \quad (2.41)$$

Note that in (2.40) contains an equal sign rather than the \approx -sign since the right-hand sign is the same for any number of time slices.

2.1.6 Quantum-Mechanical Partition Function

A path integral symmetric in p and x arises when considering the quantum-mechanical partition function defined by the trace (recall Section 1.17)

$$Z_{\text{QM}}(t_b, t_a) = \text{Tr} \left(e^{-i(t_b-t_a)\hat{H}/\hbar} \right). \quad (2.42)$$

In the local basis, the trace becomes an integral over the amplitude $(x_b t_b | x_a t_a)$ with $x_b = x_a$:

$$Z_{\text{QM}}(t_b, t_a) = \int_{-\infty}^{\infty} dx_a (x_a t_b | x_a t_a). \quad (2.43)$$

The additional trace integral over $x_{N+1} \equiv x_0$ makes the path integral for Z_{QM} symmetric in p_n and x_n :

$$\int_{-\infty}^{\infty} dx_{N+1} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] = \prod_{n=1}^{N+1} \left[\iint_{-\infty}^{\infty} \frac{dx_n dp_n}{2\pi\hbar} \right]. \quad (2.44)$$

In the continuum limit, the right-hand side is written as

$$\lim_{N \rightarrow \infty} \prod_{n=1}^{N+1} \left[\iint_{-\infty}^{\infty} \frac{dx_n dp_n}{2\pi\hbar} \right] \equiv \oint \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar}, \quad (2.45)$$

and the measures are related by

$$\int_{-\infty}^{\infty} dx_a \int_{x(t_a)=x_a}^{x(t_b)=x_a} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} \equiv \oint \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar}. \quad (2.46)$$

The symbol \oint indicates the periodic boundary condition $x(t_a) = x(t_b)$. In the momentum representation we would have similarly

$$\int_{-\infty}^{\infty} \frac{dp_a}{2\pi\hbar} \int_{p(t_a)=p_a}^{p(t_b)=p_a} \frac{\mathcal{D}'p}{2\pi\hbar} \int \mathcal{D}x \equiv \oint \frac{\mathcal{D}p}{2\pi\hbar} \int \mathcal{D}x, \quad (2.47)$$

with the periodic boundary condition $p(t_a) = p(t_b)$, and the same right-hand side. Hence, the quantum-mechanical partition function is given by the path integral

$$Z_{\text{QM}}(t_b, t_a) = \oint \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{i\mathcal{A}[p,x]/\hbar} = \oint \frac{\mathcal{D}p}{2\pi\hbar} \int \mathcal{D}x e^{i\bar{\mathcal{A}}[p,x]/\hbar}. \quad (2.48)$$

In the right-hand exponential, the action $\bar{\mathcal{A}}[p, x]$ can be replaced by $\mathcal{A}[p, x]$, since the extra terms in (2.39) are removed by the periodic boundary conditions. In the time-sliced expression, the equality is easily derived from the rearrangement of the sum (2.35), which shows that

$$\sum_{n=1}^{N+1} p_n (x_n - x_{n-1}) \Big|_{x_{N+1}=x_0} = - \sum_{n=0}^N (p_{n+1} - p_n) x_n \Big|_{p_{N+1}=p_0}. \quad (2.49)$$

In the path integral expression (2.48) for the partition function, the rules of quantum mechanics appear as a natural generalization of the rules of classical statistical mechanics, as formulated by Planck. According to these rules, each volume element in phase space $dx dp/h$ is occupied with the exponential probability $e^{-E/k_B T}$. In the path integral formulation of quantum mechanics, each volume element in the *path phase space* $\prod_n dx(t_n) dp(t_n)/h$ is associated with a pure phase factor $e^{i\mathcal{A}[p,x]/\hbar}$. We see here a manifestation of the correspondence principle which specifies the transition from classical to quantum mechanics. In path integrals, it looks somewhat more natural than in the historic formulation, where it requires the replacement of all classical phase space variables p, x by operators, a rule which was initially hard to comprehend.

2.1.7 Feynman's Configuration Space Path Integral

Actually, in his original paper, Feynman did not give the path integral formula in the above phase space formulation. Since the kinetic energy in (2.7) has usually the form $T(p, t) = p^2/2M$, he focused his attention upon the Hamiltonian

$$H = \frac{p^2}{2M} + V(x, t), \quad (2.50)$$

for which the time-sliced action (2.15) becomes

$$\mathcal{A}^N = \sum_{n=1}^{N+1} \left[p_n(x_n - x_{n-1}) - \epsilon \frac{p_n^2}{2M} - \epsilon V(x_n, t_n) \right]. \quad (2.51)$$

It can be quadratically completed to

$$\mathcal{A}^N = \sum_{n=1}^{N+1} \left[-\frac{\epsilon}{2M} \left(p_n - \frac{x_n - x_{n-1}}{\epsilon} M \right)^2 + \frac{M}{2} \epsilon \left(\frac{x_n - x_{n-1}}{\epsilon} \right)^2 - \epsilon V(x_n, t_n) \right]. \quad (2.52)$$

The momentum integrals in (2.14) may then be performed using the Fresnel integral formula (1.337), yielding

$$\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \exp \left[-\frac{i}{\hbar} \frac{\epsilon}{2M} \left(p_n - M \frac{x_n - x_{n-1}}{\epsilon} \right)^2 \right] = \frac{1}{\sqrt{2\pi\hbar i \epsilon / M}}, \quad (2.53)$$

and we arrive at the alternative representation

$$(x_b t_b | x_a t_a) \approx \frac{1}{\sqrt{2\pi\hbar i \epsilon / M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar i \epsilon / M}} \right] \exp \left(\frac{i}{\hbar} \mathcal{A}^N \right), \quad (2.54)$$

where \mathcal{A}^N is now the sum

$$\mathcal{A}^N = \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2} \left(\frac{x_n - x_{n-1}}{\epsilon} \right)^2 - V(x_n, t_n) \right], \quad (2.55)$$

with $x_{N+1} = x_b$ and $x_0 = x_a$. Here the integrals run over all paths in *configuration space* rather than phase space. They account for the fact that a quantum-mechanical particle starting from a given initial point x_a will explore all possible ways of reaching a given final point x_b . The amplitude of each path is $\exp(i\mathcal{A}^N/\hbar)$. See Fig. 2.1 for a geometric illustration of the path integration. In the continuum limit, the sum (2.55) converges towards the action in the Lagrangian form:

$$\mathcal{A}[x] = \int_{t_a}^{t_b} dt L(x, \dot{x}) = \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{x}^2 - V(x, t) \right]. \quad (2.56)$$

Note that this action is a local functional of $x(t)$ in the temporal sense as defined in Eq. (1.26).²

For the time-sliced Feynman path integral, one verifies the Schrödinger equation as follows: As in (2.20), one splits off the last slice as follows:

$$\begin{aligned} (x_b t_b | x_a t_a) &\approx \int_{-\infty}^{\infty} dx_N (x_b t_b | x_N t_N) (x_N t_N | x_a t_a) \\ &= \int_{-\infty}^{\infty} d\Delta x (x_b t_b | x_b - \Delta x t_b - \epsilon) (x_b - \Delta x t_b - \epsilon | x_a t_a), \end{aligned} \quad (2.57)$$

²A functional $F[x]$ is called local if it can be written as an integral $\int dt f(x(t), \dot{x}(t))$; it is called *ultra-local* if it has the form $\int dt f(x(t))$.

Figure 2.1 Zigzag paths, along which a point particle explores all possible ways of reaching the point x_b at a time t_b , starting from x_a at t_a . The time axis is drawn from right to left to have the same direction as the operator order in Eq. (2.2).

where

$$(x_b t_b | x_b - \Delta x t_b - \epsilon) \approx \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \exp \left\{ \epsilon \frac{i}{\hbar} \left[\frac{M}{2} \left(\frac{\Delta x}{\epsilon} \right)^2 - V(x_b, t_b) \right] \right\}. \quad (2.58)$$

We now expand the amplitude in the integral of (2.57) in a Taylor series

$$(x_b - \Delta x t_b - \epsilon | x_a t_a) = \left[1 - \Delta x \partial_{x_b} + \frac{1}{2} (\Delta x)^2 \partial_{x_b}^2 + \dots \right] (x_b, t_b - \epsilon | x_a t_a). \quad (2.59)$$

Inserting this into (2.57), the odd powers of Δx do not contribute. For the even powers, we perform the integrals using the Fresnel version of formula (1.339), and obtain zero for odd powers of Δx , and

$$\int_{-\infty}^{\infty} \frac{d\Delta x}{\sqrt{2\pi\hbar i\epsilon/M}} (\Delta x)^{2n} \exp \left\{ \epsilon \frac{i}{\hbar} \frac{M}{2} \left(\frac{\Delta x}{\epsilon} \right)^2 \right\} = \left(i \frac{\hbar\epsilon}{M} \right)^n \quad (2.60)$$

for even powers, so that the integral in (2.57) becomes

$$(x_b t_b | x_a t_a) = \left[1 + \epsilon \frac{i\hbar}{2M} \partial_{x_b}^2 + \mathcal{O}(\epsilon^2) \right] \left[1 - \epsilon \frac{i}{\hbar} V(x_b, t_b) + \mathcal{O}(\epsilon^2) \right] (x_b, t_b - \epsilon | x_a t_a). \quad (2.61)$$

In the limit $\epsilon \rightarrow 0$, this yields again the Schrödinger equation. (2.23).

In the continuum limit, we write the amplitude (2.54) as a path integral

$$(x_b t_b | x_a t_a) \equiv \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x e^{i\mathcal{A}[x]/\hbar}. \quad (2.62)$$

This is Feynman's original formula for the quantum-mechanical amplitude (2.1). It consists of a sum over all paths in configuration space with a phase factor containing the form of the action $\mathcal{A}[x]$.

We have used the same measure symbol $\mathcal{D}x$ for the paths in configuration space as for the completely different paths in phase space in the expressions (2.29), (2.38), (2.46), (2.47). There should be no danger of confusion. Note that the extra dp_n -integration in the phase space formula (2.14) results now in one extra $1/\sqrt{2\pi\hbar i\epsilon/M}$ factor in (2.54) which is not accompanied by a dx_n -integration.

The Feynman amplitude can be used to calculate the quantum-mechanical partition function (2.43) as a configuration space path integral

$$Z_{\text{QM}} = \oint \mathcal{D}x e^{i\mathcal{A}[x]/\hbar}. \quad (2.63)$$

As in (2.45), (2.46), the symbol $\oint \mathcal{D}x$ indicates that the paths have equal endpoints $x(t_a) = x(t_b)$, the path integral being the continuum limit of the product of integrals

$$\oint \mathcal{D}x \approx \prod_{n=1}^{N+1} \int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi i\hbar\epsilon/M}}. \quad (2.64)$$

There is no extra $1/\sqrt{2\pi i\hbar\epsilon/M}$ factor as in (2.54) and (2.62), due to the integration over the initial (= final) position $x_b = x_a$ representing the quantum-mechanical trace. The use of the same symbol $\oint \mathcal{D}x$ as in (2.48) should not cause any confusion since (2.48) is always accompanied by an integral $\int \mathcal{D}p$.

For the sake of generality we might point out that it is not necessary to slice the time axis in an equidistant way. In the continuum limit $N \rightarrow \infty$, the canonical path integral (2.14) is *indifferent* to the choice of the infinitesimal spacings

$$\epsilon_n = t_n - t_{n-1}. \quad (2.65)$$

The configuration space formula contains the different spacings ϵ_n in the following way: When performing the p_n integrations, we obtain a formula of the type (2.54), with each ϵ replaced by ϵ_n , i.e.,

$$\begin{aligned} (x_b t_b | x_a t_a) &\approx \frac{1}{\sqrt{2\pi\hbar i\epsilon_b/M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi i\hbar\epsilon_n/M}} \right] \\ &\times \exp \left\{ \frac{i}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2} \frac{(x_n - x_{n-1})^2}{\epsilon_n} - \epsilon_n V(x_n, t_n) \right] \right\}. \end{aligned} \quad (2.66)$$

To end this section, an important remark is necessary: It would certainly be possible to *define* the path integral for the time evolution amplitude (2.29), without going through Feynman's time-slicing procedure, as the solution of the Schrödinger differential equation [see Eq. (1.308)]:

$$[\hat{H}(-i\hbar\partial_x, x) - i\hbar\partial_t](x t | x_a t_a) = -i\hbar\delta(t - t_a)\delta(x - x_a). \quad (2.67)$$

If one possesses an orthonormal and complete set of wave functions $\psi_n(x)$ solving the time-independent Schrödinger equation $\hat{H}\psi_n(x)=E_n\psi_n(x)$, this solution is given by the spectral representation (1.323)

$$(x_b t_b | x_a t_a) = \Theta(t_b - t_a) \sum_n \psi_n(x_b) \psi_n^*(x_a) e^{-iE_n(t_b - t_a)/\hbar}, \quad (2.68)$$

where $\Theta(t)$ is the Heaviside function (1.304). This definition would, however, run contrary to the very purpose of Feynman's path integral approach, which is to understand a quantum system from the global all-time fluctuation point of view. The goal is to find all properties from the globally defined time evolution amplitude, in particular the Schrödinger wave functions.³ The global approach is usually more complicated than Schrödinger's and, as we shall see in Chapters 8 and 12–14, contains novel subtleties caused by the finite time slicing. Nevertheless, it has at least four important advantages. First, it is conceptually very attractive by formulating a quantum theory without operators which describe quantum fluctuations by close analogy with thermal fluctuations (as will be seen later in this chapter). Second, it links quantum mechanics smoothly with classical mechanics (as will be shown in Chapter 4). Third, it offers new variational procedures for the approximate study of complicated quantum-mechanical and -statistical systems (see Chapter 5). Fourth, it gives a natural geometric access to the dynamics of particles in spaces with curvature and torsion (see Chapters 10–11). This has recently led to results where the operator approach has failed due to operator-ordering problems, giving rise to a unique and correct description of the quantum dynamics of a particle in spaces with curvature and torsion. From this it is possible to derive a unique extension of Schrödinger's theory to such general spaces whose predictions can be tested in future experiments.⁴

2.2 Exact Solution for the Free Particle

In order to develop some experience with Feynman's path integral formula we consider in detail the simplest case of a free particle, which in the canonical form reads

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left(p\dot{x} - \frac{p^2}{2M} \right) \right], \quad (2.69)$$

and in the pure configuration form:

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \dot{x}^2 \right]. \quad (2.70)$$

Since the integration limits are obvious by looking at the left-hand sides of the equations, they will be omitted from now on, unless clarity requires their specification.

³Many publications claiming to have solved the path integral of a system have violated this rule by implicitly using the Schrödinger equation, although camouflaged by complicated-looking path integral notation.

⁴H. Kleinert, *Mod. Phys. Lett. A* 4, 2329 (1989) (<http://www.physik.fu-berlin.de/~kleinert/199>); *Phys. Lett. B* 236, 315 (1990) (*ibid.*[http/202](http://202)).

2.2.1 Trivial Solution

Since the Hamiltonian of a free particle $H = p^2/2M$ does not depend on x , the path integral in momentum space yields the simple result (2.40). In configuration space it reduces to simple Fourier integral Eq. (2.41). Inserting the above Hamiltonian, the integral reads

$$(x_b t_b | x_a t_a) = \int \frac{dp}{2\pi\hbar} e^{ip(x_b - x_a)/\hbar - i(t_b - t_a)p^2/2M\hbar}, \quad (2.71)$$

and can be done with the help of the Fresnel formula (2.53). The result is

$$(x_b t_b | x_a t_a) = \frac{1}{\sqrt{2\pi i\hbar(t_b - t_a)/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} \right]. \quad (2.72)$$

This result is easily generalized to D dimensions, where the free-particle amplitude (2.40) reads

$$(\mathbf{p}_b t_b | \mathbf{p}_a t_a) = (2\pi\hbar)^D \delta^{(D)}(\mathbf{p}_b - \mathbf{p}_a) e^{-i(t_b - t_a)\mathbf{p}^2/2M\hbar}, \quad (2.73)$$

and the Fourier transform yields

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \frac{1}{\sqrt{2\pi i\hbar(t_b - t_a)/M}^D} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} \right], \quad (2.74)$$

in agreement with the quantum-mechanical result in D dimensions (1.341).

2.2.2 Solution in Configuration Space

The problem can also be solved with little effort starting from Eq. (2.70). The time-sliced expression to be integrated is given by Eqs. (2.54), (2.55) with $V(x)$ set equal to zero. The resulting product of Gaussian integrals can easily be done successively using formula (1.337), from which we derive the simple rule

$$\begin{aligned} & \int dx' \frac{1}{\sqrt{2\pi i\hbar A\epsilon/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x'' - x')^2}{A\epsilon} \right] \frac{1}{\sqrt{2\pi i\hbar B\epsilon/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x' - x)^2}{B\epsilon} \right] \\ &= \frac{1}{\sqrt{2\pi i\hbar(A+B)\epsilon/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x'' - x)^2}{(A+B)\epsilon} \right], \end{aligned} \quad (2.75)$$

which leads directly to the free-particle amplitude

$$(x_b t_b | x_a t_a) = \frac{1}{\sqrt{2\pi i\hbar(N+1)\epsilon/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{(N+1)\epsilon} \right]. \quad (2.76)$$

After inserting $(N+1)\epsilon = t_b - t_a$, this agrees with the previous result (2.72). Note that the free-particle amplitude happens to be independent of the number $N+1$ of time slices.

The calculation shows that the path integrals (2.69) and (2.70) possess a simple solvable generalization to a time-dependent mass $M(t) = Mg(t)$:

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left(p\dot{x} - \frac{p^2}{2Mg(t)} \right) \right], \quad (2.77)$$

and in the pure configuration form:

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \sqrt{g} \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} g(t) \dot{x}^2(t) \right]. \quad (2.78)$$

Here the measure of integration $\int \mathcal{D}x \sqrt{g}$ symbolizes the continuum limit of the product [compare (2.54)]:

$$\int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \sqrt{g} \equiv \frac{1}{\sqrt{2\pi\hbar i\epsilon/Mg(t_b)}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar i\epsilon/Mg(t_n)}} \right]. \quad (2.79)$$

The factor $g(t_n)$ enters in each of the integrations (2.75), where the previous time slicing parameters ϵ becomes now $\epsilon_n = \epsilon/g(t_n)$, and we find instead of (2.72) the amplitude

$$(x_b t_b | x_a t_a) = \frac{1}{\sqrt{2\pi i\hbar M^{-1} \int_{t_a}^{t_b} g^{-1}(t)}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{\int_{t_a}^{t_b} g^{-1}(t)} \right]. \quad (2.80)$$

This has the Fourier representation

$$(x_b t_b | x_a t_a) = \int \frac{dp}{2\pi\hbar} \exp \left\{ \frac{i}{\hbar} \left[ip(x_b - x_a) - \frac{p^2}{2M} \int_{t_a}^{t_b} g^{-1}(t) \right] \right\}. \quad (2.81)$$

2.2.3 Fluctuations around the Classical Path

There exists yet another method of calculating this amplitude which is somewhat involved than the simple case at hand deserves, but which turns out to be useful for the treatment of a certain class of more complicated path integrals, after a suitable generalization. This method is based on summing over all path deviations from the classical path, i.e., all paths are split into the classical path

$$x_{\text{cl}}(t) = x_a + \frac{x_b - x_a}{t_b - t_a} (t - t_a), \quad (2.82)$$

along which the free particle would run following the equation of motion

$$\ddot{x}_{\text{cl}}(t) = 0, \quad (2.83)$$

plus deviations $\delta x(t)$:

$$x(t) = x_{\text{cl}}(t) + \delta x(t). \quad (2.84)$$

Since the initial and final points are fixed at x_a, x_b , respectively, the deviations vanish at the endpoints:

$$\delta x(t_a) = \delta x(t_b) = 0. \quad (2.85)$$

The deviations $\delta x(t)$ are referred to as the *quantum fluctuations* of the particle orbit. In mathematics, the boundary conditions (2.85) are referred to as *Dirichlet boundary conditions*. When inserting the decomposition (2.84) into the action we observe that due to the equation of motion (2.83) for the classical path, the action separates into the sum of a classical and a purely quadratic fluctuation term

$$\begin{aligned} & \frac{M}{2} \int_{t_a}^{t_b} dt \left\{ \dot{x}_{\text{cl}}^2(t) + 2\dot{x}_{\text{cl}}(t)\delta\dot{x}(t) + [\delta\dot{x}(t)]^2 \right\} \\ &= \frac{M}{2} \int_{t_a}^{t_b} dt \dot{x}_{\text{cl}}^2 + M\dot{x}\delta x \Big|_{t_a}^{t_b} - M \int_{t_a}^{t_b} dt \ddot{x}_{\text{cl}}\delta x + \frac{M}{2} \int_{t_a}^{t_b} dt (\delta\dot{x})^2 \\ &= \frac{M}{2} \left[\int_{t_a}^{t_b} dt \dot{x}_{\text{cl}}^2 + \int_{t_a}^{t_b} dt (\delta\dot{x})^2 \right]. \end{aligned}$$

The absence of a mixed term is a general consequence of the extremality property of the classical path,

$$\delta\mathcal{A} \Big|_{x(t)=x_{\text{cl}}(t)} = 0. \quad (2.86)$$

It implies that a quadratic *fluctuation expansion* around the classical action

$$\mathcal{A}_{\text{cl}} \equiv \mathcal{A}[x_{\text{cl}}] \quad (2.87)$$

can have no linear term in $\delta x(t)$, i.e., it must start as

$$\mathcal{A} = \mathcal{A}_{\text{cl}} + \frac{1}{2} \int_{t_a}^{t_b} dt \int_{t_a}^{t_b} dt' \frac{\delta^2 \mathcal{A}}{\delta x(t)\delta x(t')} \delta x(t)\delta x(t') \Big|_{x(t)=x_{\text{cl}}(t)} + \dots \quad (2.88)$$

With the action being a sum of two terms, the amplitude factorizes into the product of a classical amplitude $e^{i\mathcal{A}_{\text{cl}}/\hbar}$ and a fluctuation factor $F_0(t_b - t_a)$,

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x e^{i\mathcal{A}[x]/\hbar} = e^{i\mathcal{A}_{\text{cl}}/\hbar} F_0(t_b, t_a). \quad (2.89)$$

For the free particle with the classical action

$$\mathcal{A}_{\text{cl}} = \int_{t_a}^{t_b} dt \frac{M}{2} \dot{x}_{\text{cl}}^2, \quad (2.90)$$

the function factor $F_0(t_b - t_a)$ is given by the path integral

$$F_0(t_b - t_a) = \int \mathcal{D}\delta x(t) \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\delta\dot{x})^2 \right]. \quad (2.91)$$

Due to the vanishing of $\delta x(t)$ at the endpoints, this does not depend on x_b, x_a but only on the initial and final times t_b, t_a . The time translational invariance reduces

this dependence further to the time difference $t_b - t_a$. The subscript zero of $F_0(t_b - t_a)$ indicates the free-particle nature of the fluctuation factor. After inserting (2.82) into (2.90), we find immediately

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a}. \quad (2.92)$$

The fluctuation factor, on the other hand, requires the evaluation of the multiple integral

$$F_0^N(t_b - t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{d\delta x_n}{\sqrt{2\pi\hbar i\epsilon/M}} \right] \exp\left(\frac{i}{\hbar} \mathcal{A}_{\text{fl}}^N\right), \quad (2.93)$$

where $\mathcal{A}_{\text{fl}}^N$ is the time-sliced fluctuation action

$$\mathcal{A}_{\text{fl}}^N = \frac{M}{2} \epsilon \sum_{n=1}^{N+1} \left(\frac{\delta x_n - \delta x_{n-1}}{\epsilon} \right)^2. \quad (2.94)$$

At the end, we have to take the continuum limit

$$N \rightarrow \infty, \quad \epsilon = (t_b - t_a)/(N + 1) \rightarrow 0.$$

2.2.4 Fluctuation Factor

The remainder of this section will be devoted to calculating the fluctuation factor (2.93). Before doing this, we shall develop a general technique for dealing with such time-sliced expressions. Due to the frequent appearance of the fluctuating δx -variables, we shorten the notation by omitting all δ 's and working only with x -variables.

A useful device for manipulating sums on a sliced time axis such as (2.94) is the difference operator ∇ and its conjugate $\bar{\nabla}$, defined by

$$\nabla x(t) \equiv \frac{1}{\epsilon} [x(t + \epsilon) - x(t)], \quad \bar{\nabla} x(t) \equiv \frac{1}{\epsilon} [x(t) - x(t - \epsilon)]. \quad (2.95)$$

They are two different discrete versions of the time derivative ∂_t , to which both reduce in the continuum limit $\epsilon \rightarrow 0$:

$$\nabla, \bar{\nabla} \xrightarrow{\epsilon \rightarrow 0} \partial_t, \quad (2.96)$$

if they act upon differentiable functions. Since the discretized time axis with $N + 1$ steps constitutes a one-dimensional lattice, the difference operators $\nabla, \bar{\nabla}$ are also called *lattice derivatives*.

For the coordinates $x_n = x(t_n)$ at the discrete times t_n we write

$$\begin{aligned} \nabla x_n &= \frac{1}{\epsilon} (x_{n+1} - x_n), & N \geq n \geq 0, \\ \bar{\nabla} x_n &= \frac{1}{\epsilon} (x_n - x_{n-1}), & N + 1 \geq n \geq 1. \end{aligned} \quad (2.97)$$

The time-sliced action (2.94) can then be expressed in terms of ∇x_n or $\bar{\nabla} x_n$ as (writing x_n instead of δx_n)

$$\mathcal{A}_{\text{fl}}^N = \frac{M}{2} \epsilon \sum_{n=0}^N (\nabla x_n)^2 = \frac{M}{2} \epsilon \sum_{n=1}^{N+1} (\bar{\nabla} x_n)^2. \quad (2.98)$$

In this notation, the limit $\epsilon \rightarrow 0$ is most obvious: The sum $\epsilon \sum_n$ goes into the integral $\int_{t_a}^{t_b} dt$, whereas both $(\nabla x_n)^2$ and $(\bar{\nabla} x_n)^2$ tend to \dot{x}^2 , so that

$$\mathcal{A}_{\text{fl}}^N \rightarrow \int_{t_a}^{t_b} dt \frac{M}{2} \dot{x}^2. \quad (2.99)$$

Thus, the time-sliced action becomes the Lagrangian action.

Lattice derivatives have properties quite similar to ordinary derivatives. One only has to be careful in distinguishing ∇ and $\bar{\nabla}$. For example, they allow for the useful operation *summation by parts* which is analogous to integration by parts. Recall the rule for the integration by parts

$$\int_{t_a}^{t_b} dt g(t) \dot{f}(t) = g(t) f(t) \Big|_{t_a}^{t_b} - \int_{t_a}^{t_b} dt \dot{g}(t) f(t). \quad (2.100)$$

On the lattice, this relation yields for functions $f(t) \rightarrow x_n$ and $g(t) \rightarrow p_n$:

$$\epsilon \sum_{n=1}^{N+1} p_n \bar{\nabla} x_n = p_n x_n \Big|_0^{N+1} - \epsilon \sum_{n=0}^N (\nabla p_n) x_n. \quad (2.101)$$

This follows directly by rewriting (2.35).

For functions vanishing at the endpoints, i.e., for $x_{N+1} = x_0 = 0$, we can omit the surface terms and shift the range of the sum on the right-hand side to obtain the simple formula [see also Eq. (2.49)]

$$\sum_{n=1}^{N+1} p_n \bar{\nabla} x_n = - \sum_{n=0}^N (\nabla p_n) x_n = - \sum_{n=1}^{N+1} (\nabla p_n) x_n. \quad (2.102)$$

The same thing holds if both $p(t)$ and $x(t)$ are periodic in the interval $t_b - t_a$, so that $p_0 = p_{N+1}$, $x_0 = x_{N+1}$. In this case, it is possible to shift the sum on the right-hand side by one unit arriving at the more symmetric-looking formula

$$\sum_{n=1}^{N+1} p_n \bar{\nabla} x_n = - \sum_{n=1}^{N+1} (\nabla p_n) x_n. \quad (2.103)$$

In the time-sliced action (2.94) the quantum fluctuations x_n ($\hat{=} \delta x_n$) vanish at the ends, so that (2.102) can be used to rewrite

$$\sum_{n=1}^{N+1} (\bar{\nabla} x_n)^2 = - \sum_{n=1}^N x_n \nabla \bar{\nabla} x_n. \quad (2.104)$$

In the ∇x_n -form of the action (2.98), the same expression is obtained by applying formula (2.102) from the right- to the left-hand side and using the vanishing of x_0 and x_{N+1} :

$$\sum_{n=0}^N (\nabla x_n)^2 = - \sum_{n=1}^{N+1} x_n \overline{\nabla} \nabla x_n = - \sum_{n=1}^N x_n \overline{\nabla} \nabla x_n. \quad (2.105)$$

The right-hand sides in (2.104) and (2.105) can be written in matrix form as

$$\begin{aligned} - \sum_{n=1}^N x_n \nabla \overline{\nabla} x_n &\equiv - \sum_{n,n'=1}^N x_n (\nabla \overline{\nabla})_{nn'} x_{n'}, \\ - \sum_{n=1}^N x_n \overline{\nabla} \nabla x_n &\equiv - \sum_{n,n'=1}^N x_n (\overline{\nabla} \nabla)_{nn'} x_{n'}, \end{aligned} \quad (2.106)$$

with the same $N \times N$ -matrix

$$\nabla \overline{\nabla} \equiv \overline{\nabla} \nabla \equiv \frac{1}{\epsilon^2} \begin{pmatrix} -2 & 1 & 0 & \dots & 0 & 0 & 0 \\ 1 & -2 & 1 & \dots & 0 & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & 0 & \dots & 1 & -2 & 1 \\ 0 & 0 & 0 & \dots & 0 & 1 & -2 \end{pmatrix}. \quad (2.107)$$

This is obviously the lattice version of the double time derivative ∂_t^2 , to which it reduces in the continuum limit $\epsilon \rightarrow 0$. It will therefore be called the *lattice Laplacian*.

A further common property of lattice and ordinary derivatives is that they can both be diagonalized by going to Fourier components. When decomposing

$$x(t) = \int_{-\infty}^{\infty} d\omega e^{-i\omega t} x(\omega), \quad (2.108)$$

and applying the lattice derivative ∇ , we find

$$\begin{aligned} \nabla x(t_n) &= \int_{-\infty}^{\infty} d\omega \frac{1}{\epsilon} (e^{-i\omega(t_n+\epsilon)} - e^{-i\omega t_n}) x(\omega) \\ &= \int_{-\infty}^{\infty} d\omega e^{-i\omega t_n} \frac{1}{\epsilon} (e^{-i\omega\epsilon} - 1) x(\omega). \end{aligned} \quad (2.109)$$

Hence, on the Fourier components, ∇ has the eigenvalues

$$\frac{1}{\epsilon} (e^{-i\omega\epsilon} - 1). \quad (2.110)$$

In the continuum limit $\epsilon \rightarrow 0$, this becomes the eigenvalue of the ordinary time derivative ∂_t , i.e., $-i$ times the frequency of the Fourier component ω . As a reminder of this we shall denote the eigenvalue of $i\nabla$ by Ω and have

$$(i\nabla x)(\omega) = \Omega x(\omega) \equiv \frac{i}{\epsilon} (e^{-i\omega\epsilon} - 1) x(\omega). \quad (2.111)$$

For the conjugate lattice derivative we find similarly

$$(i\bar{\nabla}x)(\omega) = \bar{\Omega} x(\omega) \equiv -\frac{i}{\epsilon}(e^{i\omega\epsilon} - 1) x(\omega), \quad (2.112)$$

where $\bar{\Omega}$ is the complex-conjugate number of Ω , i.e., $\bar{\Omega} \equiv \Omega^*$. As a consequence, the eigenvalues of the negative lattice Laplacian $-\nabla\bar{\nabla} \equiv -\bar{\nabla}\nabla$ are real and nonnegative:

$$\frac{i}{\epsilon}(e^{-i\omega\epsilon} - 1)\frac{i}{\epsilon}(1 - e^{i\omega\epsilon}) = \frac{1}{\epsilon^2}[2 - 2\cos(\omega\epsilon)] \geq 0. \quad (2.113)$$

Of course, Ω and $\bar{\Omega}$ have the same continuum limit ω .

When decomposing the quantum fluctuations $x(t)$ [$\hat{=} \delta x(t)$] into their Fourier components, not all eigenfunctions occur. Since $x(t)$ vanishes at the initial time $t = t_a$, the decomposition can be restricted to the sine functions and we may expand

$$x(t) = \int_0^\infty d\omega \sin \omega(t - t_a) x(\omega). \quad (2.114)$$

The vanishing at the final time $t = t_b$ is enforced by a restriction of the frequencies ω to the discrete values

$$\nu_m = \frac{\pi m}{t_b - t_a} = \frac{\pi m}{(N + 1)\epsilon}. \quad (2.115)$$

Thus we are dealing with the Fourier series

$$x(t) = \sum_{m=1}^{\infty} \sqrt{\frac{2}{(t_b - t_a)}} \sin \nu_m(t - t_a) x(\nu_m) \quad (2.116)$$

with real Fourier components $x(\nu_m)$. A further restriction arises from the fact that for finite ϵ , the series has to represent $x(t)$ only at the discrete points $x(t_n)$, $n = 0, \dots, N + 1$. It is therefore sufficient to carry the sum only up to $m = N$ and to expand $x(t_n)$ as

$$x(t_n) = \sum_{m=1}^N \sqrt{\frac{2}{N + 1}} \sin \nu_m(t_n - t_a) x(\nu_m), \quad (2.117)$$

where a factor $\sqrt{\epsilon}$ has been removed from the Fourier components, for convenience. The expansion functions are orthogonal,

$$\frac{2}{N + 1} \sum_{n=1}^N \sin \nu_m(t_n - t_a) \sin \nu_{m'}(t_n - t_a) = \delta_{mm'}, \quad (2.118)$$

and complete:

$$\frac{2}{N + 1} \sum_{m=1}^N \sin \nu_m(t_n - t_a) \sin \nu_m(t_{n'} - t_a) = \delta_{nn'} \quad (2.119)$$

(where $0 < m, m' < N + 1$). The orthogonality relation follows by rewriting the left-hand side of (2.118) in the form

$$\frac{2}{N+1} \frac{1}{2} \operatorname{Re} \sum_{n=0}^{N+1} \left\{ \exp \left[\frac{i\pi(m-m')}{N+1} n \right] - \exp \left[\frac{i\pi(m+m')}{N+1} n \right] \right\}, \quad (2.120)$$

with the sum extended without harm by a trivial term at each end. Being of the geometric type, this can be calculated right away. For $m = m'$ the sum adds up to 1, while for $m \neq m'$ it becomes

$$\frac{2}{N+1} \frac{1}{2} \operatorname{Re} \left[\frac{1 - e^{i\pi(m-m')} e^{i\pi(m-m')/(N+1)}}{1 - e^{i\pi(m-m')/(N+1)}} - (m' \rightarrow -m') \right]. \quad (2.121)$$

The first expression in the curly brackets is equal to 1 for even $m - m' \neq 0$; while being imaginary for odd $m - m'$ [since $(1 + e^{i\alpha})/(1 - e^{i\alpha})$ is equal to $(1 + e^{i\alpha})(1 - e^{-i\alpha})/|1 - e^{i\alpha}|^2$ with the imaginary numerator $e^{i\alpha} - e^{-i\alpha}$]. For the second term the same thing holds true for even and odd $m + m' \neq 0$, respectively. Since $m - m'$ and $m + m'$ are either both even or both odd, the right-hand side of (2.118) vanishes for $m \neq m'$ [remembering that $m, m' \in [0, N + 1]$ in the expansion (2.117), and thus in (2.121)]. The proof of the completeness relation (2.119) can be carried out similarly.

Inserting now the expansion (2.117) into the time-sliced fluctuation action (2.94), the orthogonality relation (2.118) yields

$$\mathcal{A}_{\text{fl}}^N = \frac{M}{2} \epsilon \sum_{n=0}^N (\nabla x_n)^2 = \frac{M}{2} \epsilon \sum_{m=1}^{N+1} x(\nu_m) \Omega_m \bar{\Omega}_m x(\nu_m). \quad (2.122)$$

Thus the action decomposes into a sum of independent quadratic terms involving the discrete set of eigenvalues

$$\Omega_m \bar{\Omega}_m = \frac{1}{\epsilon^2} [2 - 2 \cos(\nu_m \epsilon)] = \frac{1}{\epsilon^2} \left[2 - 2 \cos \left(\frac{\pi m}{N+1} \right) \right], \quad (2.123)$$

and the fluctuation factor (2.93) becomes

$$F_0^N(t_b - t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar i\epsilon/M}} \right] \times \prod_{m=1}^N \exp \left\{ \frac{i}{\hbar} \frac{M}{2} \epsilon \Omega_m \bar{\Omega}_m [x(\nu_m)]^2 \right\}. \quad (2.124)$$

Before performing the integrals, we must transform the measure of integration from the local variables x_n to the Fourier components $x(\nu_m)$. Due to the orthogonality relation (2.118), the transformation has a unit determinant implying that

$$\prod_{n=1}^N dx_n = \prod_{m=1}^N dx(\nu_m). \quad (2.125)$$

With this, Eq. (2.124) can be integrated with the help of Fresnel's formula (1.337). The result is

$$F_0^N(t_b - t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{m=1}^N \frac{1}{\sqrt{\epsilon^2\Omega_m\bar{\Omega}_m}}. \quad (2.126)$$

To calculate the product we use the formula⁵

$$\prod_{m=1}^N \left(1 + x^2 - 2x \cos \frac{m\pi}{N+1}\right) = \frac{x^{2(N+1)} - 1}{x^2 - 1}. \quad (2.127)$$

Taking the limit $x \rightarrow 1$ gives

$$\prod_{m=1}^N \epsilon^2\Omega_m\bar{\Omega}_m = \prod_{m=1}^N 2 \left(1 - \cos \frac{m\pi}{N+1}\right) = N + 1. \quad (2.128)$$

The time-sliced fluctuation factor of a free particle is therefore simply

$$F_0^N(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar(N+1)\epsilon/M}}, \quad (2.129)$$

or, expressed in terms of $t_b - t_a$,

$$F_0(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar(t_b - t_a)/M}}. \quad (2.130)$$

As in the amplitude (2.72) we have dropped the superscript N since this final result is independent of the number of time slices.

Note that the dimension of the fluctuation factor is 1/length. In fact, one may introduce a length scale associated with the time interval $t_b - t_a$,

$$l(t_b - t_a) \equiv \sqrt{2\pi\hbar(t_b - t_a)/M}, \quad (2.131)$$

and write

$$F_0(t_b - t_a) = \frac{1}{\sqrt{i}l(t_b - t_a)}. \quad (2.132)$$

With (2.130) and (2.92), the full time evolution amplitude of a free particle (2.89) is again given by (2.72)

$$\langle x_b t_b | x_a t_a \rangle = \frac{1}{\sqrt{2\pi i\hbar(t_b - t_a)/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} \right]. \quad (2.133)$$

It is instructive to present an alternative calculation of the product of eigenvalues in (2.126) which does not make use of the Fourier decomposition and works entirely in configuration space. We observe that the product

$$\prod_{m=1}^N \epsilon^2\Omega_m\bar{\Omega}_m \quad (2.134)$$

⁵I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 1.396.2.

is the determinant of the diagonalized $N \times N$ -matrix $-\epsilon^2 \nabla \bar{\nabla}$. This follows from the fact that for any matrix, the determinant is the product of its eigenvalues. The product (2.134) is therefore also called the *fluctuation determinant* of the free particle and written

$$\prod_{m=1}^N \epsilon^2 \Omega_m \bar{\Omega}_m \equiv \det_N(-\epsilon^2 \nabla \bar{\nabla}). \quad (2.135)$$

With this notation, the fluctuation factor (2.126) reads

$$F_0^N(t_b - t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \left[\det_N(-\epsilon^2 \nabla \bar{\nabla}) \right]^{-1/2}. \quad (2.136)$$

Now one realizes that the determinant of $\epsilon^2 \bar{\nabla} \nabla$ can be found very simply from the explicit $N \times N$ matrix (2.107) by induction: For $N = 1$ we see directly that

$$\det_{N=1}(-\epsilon^2 \nabla \bar{\nabla}) = |2| = 2. \quad (2.137)$$

For $N = 2$, the determinant is

$$\det_{N=2}(-\epsilon^2 \nabla \bar{\nabla}) = \begin{vmatrix} 2 & -1 \\ -1 & 2 \end{vmatrix} = 3. \quad (2.138)$$

A recursion relation is obtained by developing the determinant twice with respect to the first row:

$$\det_N(-\epsilon^2 \nabla \bar{\nabla}) = 2 \det_{N-1}(-\epsilon^2 \nabla \bar{\nabla}) - \det_{N-2}(-\epsilon^2 \nabla \bar{\nabla}). \quad (2.139)$$

With the initial condition (2.137), the solution is

$$\det_N(-\epsilon^2 \nabla \bar{\nabla}) = N + 1, \quad (2.140)$$

in agreement with the previous result (2.128).

2.2.5 Finite Slicing Properties of Free-Particle Amplitude

The time-sliced free-particle time evolution amplitude (2.76) happens to be independent of the number N of time slices used for their calculation. We have pointed this out earlier for the fluctuation factor (2.129). Let us study the origin of this independence for the classical action in the exponent. The difference equation of motion

$$-\bar{\nabla} \nabla x(t) = 0 \quad (2.141)$$

is solved by the same linear function

$$x(t) = At + B, \quad (2.142)$$

as in the continuum. Imposing the initial conditions gives

$$x_{\text{cl}}(t_n) = x_a + (x_b - x_a) \frac{n}{N+1}. \quad (2.143)$$

The time-sliced action of the fluctuations is calculated, via a summation by parts on the lattice [see (2.101)]. Using the difference equation $\bar{\nabla} \nabla x_{\text{cl}} = 0$, we find

$$\begin{aligned} \mathcal{A}_{\text{cl}} &= \epsilon \sum_{n=1}^{N+1} \frac{M}{2} (\bar{\nabla} x_{\text{cl}})^2 \\ &= \frac{M}{2} \left(x_{\text{cl}} \nabla x_{\text{cl}} \Big|_{n=0}^{N+1} - \epsilon \sum_{n=0}^N x_{\text{cl}} \nabla \bar{\nabla} x_{\text{cl}} \right) \\ &= \frac{M}{2} x_{\text{cl}} \nabla x_{\text{cl}} \Big|_{n=0}^{N+1} = \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a}. \end{aligned} \quad (2.144)$$

This coincides with the continuum action for any number of time slices.

In the operator formulation of quantum mechanics, the ϵ -independence of the amplitude of the free particle follows from the fact that in the absence of a potential $V(x)$, the two sides of the Trotter formula (2.26) coincide for any N .

2.3 Exact Solution for Harmonic Oscillator

A further problem to be solved along similar lines is the time evolution amplitude of the linear oscillator

$$\begin{aligned} (x_b t_b | x_a t_a) &= \int \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left\{ \frac{i}{\hbar} \mathcal{A}[p, x] \right\} \\ &= \int \mathcal{D}x \exp \left\{ \frac{i}{\hbar} \mathcal{A}[x] \right\}, \end{aligned} \quad (2.145)$$

with the canonical action

$$\mathcal{A}[p, x] = \int_{t_a}^{t_b} dt \left(p\dot{x} - \frac{1}{2M} p^2 - \frac{M\omega^2}{2} x^2 \right), \quad (2.146)$$

and the Lagrangian action

$$\mathcal{A}[x] = \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}^2 - \omega^2 x^2). \quad (2.147)$$

2.3.1 Fluctuations around the Classical Path

As before, we proceed with the Lagrangian path integral, starting from the time-sliced form of the action

$$\mathcal{A}^N = \epsilon \frac{M}{2} \sum_{n=1}^{N+1} [(\bar{\nabla} x_n)^2 - \omega^2 x_n^2]. \quad (2.148)$$

The path integral is again a product of Gaussian integrals which can be evaluated successively. In contrast to the free-particle case, however, the direct evaluation is now quite complicated; it will be presented in Appendix 2B. It is far easier to employ the fluctuation expansion, splitting the paths into a classical path $x_{\text{cl}}(t)$ plus fluctuations $\delta x(t)$. The fluctuation expansion makes use of the fact that the action is quadratic in $x = x_{\text{cl}} + \delta x$ and decomposes into the sum of a classical part

$$\mathcal{A}_{\text{cl}} = \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}_{\text{cl}}^2 - \omega^2 x_{\text{cl}}^2), \quad (2.149)$$

and a fluctuation part

$$\mathcal{A}_{\text{fl}} = \int_{t_a}^{t_b} dt \frac{M}{2} [(\delta \dot{x})^2 - \omega^2 (\delta x)^2], \quad (2.150)$$

with the boundary condition

$$\delta x(t_a) = \delta x(t_b) = 0. \quad (2.151)$$

There is no mixed term, due to the extremality of the classical action. The equation of motion is

$$\ddot{x}_{\text{cl}} = -\omega^2 x_{\text{cl}}. \quad (2.152)$$

Thus, as for a free-particle, the total time evolution amplitude splits into a classical and a fluctuation factor:

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x e^{iA[x]/\hbar} = e^{i\mathcal{A}_{\text{cl}}/\hbar} F_{\omega}(t_b - t_a). \quad (2.153)$$

The subscript of F_{ω} records the frequency of the oscillator.

The classical orbit connecting initial and final points is obviously

$$x_{\text{cl}}(t) = \frac{x_b \sin \omega(t - t_a) + x_a \sin \omega(t_b - t)}{\sin \omega(t_b - t_a)}. \quad (2.154)$$

Note that this equation only makes sense if $t_b - t_a$ is not equal to an integer multiple of π/ω which we shall always assume from now on.⁶

After an integration by parts we can rewrite the classical action \mathcal{A}_{cl} as

$$\mathcal{A}_{\text{cl}} = \int_{t_a}^{t_b} dt \frac{M}{2} [x_{\text{cl}}(-\ddot{x}_{\text{cl}} - \omega^2 x_{\text{cl}})] + \frac{M}{2} x_{\text{cl}} \dot{x}_{\text{cl}} \Big|_{t_a}^{t_b}. \quad (2.155)$$

The first term vanishes due to the equation of motion (2.152), and we obtain the simple expression

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} [x_{\text{cl}}(t_b) \dot{x}_{\text{cl}}(t_b) - x_{\text{cl}}(t_a) \dot{x}_{\text{cl}}(t_a)]. \quad (2.156)$$

⁶For subtleties in the immediate neighborhood of the singularities which are known as *caustic phenomena*, see Notes and References at the end of the chapter, as well as Section 4.8.

Since

$$\dot{x}_{\text{cl}}(t_a) = \frac{\omega}{\sin \omega(t_b - t_a)} [x_b - x_a \cos \omega(t_b - t_a)], \quad (2.157)$$

$$\dot{x}_{\text{cl}}(t_b) = \frac{\omega}{\sin \omega(t_b - t_a)} [x_b \cos \omega(t_b - t_a) - x_a], \quad (2.158)$$

we can rewrite the classical action as

$$\mathcal{A}_{\text{cl}} = \frac{M\omega}{2 \sin \omega(t_b - t_a)} [(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a]. \quad (2.159)$$

2.3.2 Fluctuation Factor

We now turn to the fluctuation factor. With the matrix notation for the lattice operator $-\nabla\bar{\nabla} - \omega^2$, we have to solve the multiple integral

$$F_{\omega}^N(t_b, t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar i\epsilon/M}} \right] \times \exp \left\{ \frac{i}{\hbar} \frac{M}{2} \epsilon \sum_{n,n'=1}^N \delta x_n [-\nabla\bar{\nabla} - \omega^2]_{nn'} \delta x_{n'} \right\}. \quad (2.160)$$

When going to the Fourier components of the paths, the integral factorizes in the same way as for the free-particle expression (2.124). The only difference lies in the eigenvalues of the fluctuation operator which are now

$$\Omega_m \bar{\Omega}_m - \omega^2 = \frac{1}{\epsilon^2} [2 - 2 \cos(\nu_m \epsilon)] - \omega^2 \quad (2.161)$$

instead of $\Omega_m \bar{\Omega}_m$. For times t_b, t_a where all eigenvalues are positive (which will be specified below) we obtain from the upper part of the Fresnel formula (1.337) directly

$$F_{\omega}^N(t_b, t_a) = \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{m=1}^N \frac{1}{\sqrt{\epsilon^2 \Omega_m \bar{\Omega}_m - \epsilon^2 \omega^2}}. \quad (2.162)$$

The product of these eigenvalues is found by introducing an auxiliary frequency $\tilde{\omega}$ satisfying

$$\sin \frac{\epsilon \tilde{\omega}}{2} \equiv \frac{\epsilon \omega}{2}. \quad (2.163)$$

Then we decompose the product as

$$\begin{aligned} \prod_{m=1}^N [\epsilon^2 \Omega_m \bar{\Omega}_m - \epsilon^2 \omega^2] &= \prod_{m=1}^N [\epsilon^2 \Omega_m \bar{\Omega}_m] \prod_{m=1}^N \left[\frac{\epsilon^2 \Omega_m \bar{\Omega}_m - \epsilon^2 \omega^2}{\epsilon^2 \Omega_m \bar{\Omega}_m} \right] \\ &= \prod_{m=1}^N [\epsilon^2 \Omega_m \bar{\Omega}_m] \left[\prod_{m=1}^N \left(1 - \frac{\sin^2 \frac{\epsilon \tilde{\omega}}{2}}{\sin^2 \frac{m\pi}{2(N+1)}} \right) \right]. \end{aligned} \quad (2.164)$$

The first factor is equal to $(N + 1)$ by (2.128). The second factor, the product of the ratios of the eigenvalues, is found from the standard formula⁷

$$\prod_{m=1}^N \left(1 - \frac{\sin^2 x}{\sin^2 \frac{m\pi}{2(N+1)}} \right) = \frac{1}{\sin 2x} \frac{\sin[2(N+1)x]}{(N+1)}. \quad (2.165)$$

With $x = \tilde{\omega}\epsilon/2$, we arrive at the fluctuation determinant

$$\det_N(-\epsilon^2 \nabla \bar{\nabla} - \epsilon^2 \omega^2) = \prod_{m=1}^N [\epsilon^2 \Omega_m \bar{\Omega}_m - \epsilon^2 \omega^2] = \frac{\sin \tilde{\omega}(t_b - t_a)}{\sin \epsilon \tilde{\omega}}, \quad (2.166)$$

and the fluctuation factor is given by

$$F_{\omega}^N(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \sqrt{\frac{\sin \tilde{\omega} \epsilon}{\epsilon \sin \tilde{\omega}(t_b - t_a)}}, \quad t_b - t_a < \pi / \tilde{\omega}, \quad (2.167)$$

where, as we have agreed earlier in Eq. (1.337), \sqrt{i} means $e^{i\pi/4}$, and $t_b - t_a$ is always larger than zero.

2.3.3 The $i\eta$ -Prescription and Maslov-Morse Index

The result (2.167) is initially valid only for

$$t_b - t_a < \pi / \tilde{\omega}. \quad (2.168)$$

In this time interval, all eigenvalues in the fluctuation determinant (2.166) are positive, and the upper version of the Fresnel formula (1.337) applies to each of the integrals in (2.160) [this was assumed in deriving (2.162)]. If $t_b - t_a$ grows larger than $\pi / \tilde{\omega}$, the smallest eigenvalue $\Omega_1 \bar{\Omega}_1 - \omega^2$ becomes negative and the integration over the associated Fourier component has to be done according to the lower case of the Fresnel formula (1.337). The resulting amplitude carries an extra phase factor $e^{-i\pi/2}$ and remains valid until $t_b - t_a$ becomes larger than $2\pi / \tilde{\omega}$, where the second eigenvalue becomes negative introducing a further phase factor $e^{-i\pi/2}$.

All phase factors emerge naturally if we associate with the oscillator frequency ω an infinitesimal negative imaginary part, replacing everywhere ω by $\omega - i\eta$ with an infinitesimal $\eta > 0$. This is referred to as the $i\eta$ -prescription. Physically, it amounts to attaching an infinitesimal damping term to the oscillator, so that the amplitude behaves like $e^{-i\omega t - \eta t}$ and dies down to zero after a very long time (as opposed to an unphysical antidamping term which would make it diverge after a long time). Now, each time that $t_b - t_a$ passes an integer multiple of $\pi / \tilde{\omega}$, the square root of $\sin \tilde{\omega}(t_b - t_a)$ in (2.167) passes a singularity in a specific way which ensures the proper phase.⁸ With such an $i\eta$ -prescription it will be superfluous to restrict $t_b - t_a$ to the

⁷I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 1.391.1.

⁸In the square root, we may equivalently assume $t_b - t_a$ to carry a small negative imaginary part. For a detailed discussion of the phases of the fluctuation factor in the literature, see Notes and References at the end of the chapter.

range (2.168). Nevertheless it will sometimes be useful to exhibit the phase factor arising in this way in the fluctuation factor (2.167) for $t_b - t_a > \pi/\tilde{\omega}$ by writing

$$F_\omega^N(t_b, t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\sin \tilde{\omega}\epsilon}{\epsilon |\sin \tilde{\omega}(t_b - t_a)|}} e^{-i\nu\pi/2}, \quad (2.169)$$

where ν is the number of zeros encountered in the denominator along the trajectory. This number is called the *Maslov-Morse index* of the trajectory⁹.

2.3.4 Continuum Limit

Let us now go to the continuum limit, $\epsilon \rightarrow 0$. Then the auxiliary frequency $\tilde{\omega}$ tends to ω and the fluctuation determinant becomes

$$\det_N(-\epsilon^2 \nabla \bar{\nabla} - \epsilon^2 \omega^2) \xrightarrow{\epsilon \rightarrow 0} \frac{\sin \omega(t_b - t_a)}{\omega \epsilon}. \quad (2.170)$$

The fluctuation factor $F_\omega^N(t_b - t_a)$ goes over into

$$F_\omega(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}}, \quad (2.171)$$

with the phase for $t_b - t_a > \pi/\omega$ determined as above.

In the limit $\omega \rightarrow 0$, both fluctuation factors agree, of course, with the free-particle result (2.130).

In the continuum limit, the ratios of eigenvalues in (2.164) can also be calculated in the following simple way. We perform the limit $\epsilon \rightarrow 0$ directly in each factor. This gives

$$\begin{aligned} \frac{\epsilon^2 \Omega_m \bar{\Omega}_m - \epsilon^2 \omega^2}{\epsilon^2 \Omega_m \bar{\Omega}_m} &= 1 - \frac{\epsilon^2 \omega^2}{2 - 2 \cos(\nu_m \epsilon)} \\ &\xrightarrow{\epsilon \rightarrow 0} 1 - \frac{\omega^2 (t_b - t_a)^2}{\pi^2 m^2}. \end{aligned} \quad (2.172)$$

As the number N goes to infinity we wind up with an infinite product of these factors. Using the well-known infinite-product formula for the sine function¹⁰

$$\sin x = x \prod_{m=1}^{\infty} \left(1 - \frac{x^2}{m^2 \pi^2} \right), \quad (2.173)$$

we find, with $x = \omega(t_b - t_a)$,

$$\prod_m \frac{\Omega_m \bar{\Omega}_m}{\Omega_m \bar{\Omega}_m - \omega^2} \xrightarrow{\epsilon \rightarrow 0} \prod_{m=1}^{\infty} \frac{\nu_m^2}{\nu_m^2 - \omega^2} = \frac{\omega(t_b - t_a)}{\sin \omega(t_b - t_a)}, \quad (2.174)$$

⁹V.P. Maslov and M.V. Fedoriuk, *Semi-Classical Approximations in Quantum Mechanics*, Reidel, Boston, 1981.

¹⁰I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 1.431.1.

and obtain once more the fluctuation factor in the continuum (2.171).

Multiplying the fluctuation factor with the classical amplitude, the time evolution amplitude of the linear oscillator in the continuum reads

$$\begin{aligned} (x_b t_b | x_a t_a) &= \int \mathcal{D}x(t) \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}^2 - \omega^2 x^2) \right] \\ &= \frac{1}{\sqrt{2\pi i \hbar / M}} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}} \\ &\quad \times \exp \left\{ \frac{i}{2\hbar} \frac{M\omega}{\sin \omega(t_b - t_a)} [(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a] \right\}. \end{aligned} \quad (2.175)$$

The result can easily be extended to any number D of dimensions, where the action is

$$\mathcal{A} = \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{\mathbf{x}}^2 - \omega^2 \mathbf{x}^2). \quad (2.176)$$

Being quadratic in \mathbf{x} , the action is the sum of the actions of each component leading to the factorized amplitude:

$$\begin{aligned} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) &= \prod_{i=1}^D (x_b^i t_b | x_a^i t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}^D} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}}^D \\ &\quad \times \exp \left\{ \frac{i}{2\hbar} \frac{M\omega}{\sin \omega(t_b - t_a)} [(\mathbf{x}_b^2 + \mathbf{x}_a^2) \cos \omega(t_b - t_a) - 2\mathbf{x}_b \mathbf{x}_a] \right\}, \end{aligned} \quad (2.177)$$

where the phase of the second square root for $t_b - t_a > \pi/\omega$ is determined as in the one-dimensional case [see Eq. (1.546)].

2.3.5 Useful Fluctuation Formulas

It is worth realizing that when performing the continuum limit in the ratio of eigenvalues (2.174), we have actually calculated the ratio of the functional determinants of the *differential* operators

$$\frac{\det(-\partial_t^2 - \omega^2)}{\det(-\partial_t^2)}. \quad (2.178)$$

Indeed, the eigenvalues of $-\partial_t^2$ in the space of real fluctuations vanishing at the endpoints are simply

$$\nu_m^2 = \left(\frac{\pi m}{t_b - t_a} \right)^2, \quad (2.179)$$

so that the ratio (2.178) is equal to the product

$$\frac{\det(-\partial_t^2 - \omega^2)}{\det(-\partial_t^2)} = \prod_{m=1}^{\infty} \frac{\nu_m^2 - \omega^2}{\nu_m^2}, \quad (2.180)$$

which is the same as (2.174). This observation should, however, not lead us to believe that the entire fluctuation factor

$$F_\omega(t_b - t_a) = \int \mathcal{D}\delta x \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} [(\delta \dot{x})^2 - \omega^2 (\delta x)^2] \right\} \quad (2.181)$$

could be calculated via the continuum determinant

$$F_\omega(t_b, t_a) \xrightarrow{\epsilon \rightarrow 0} \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \frac{1}{\sqrt{\det(-\partial_t^2 - \omega^2)}} \quad (\text{false}). \quad (2.182)$$

The product of eigenvalues in $\det(-\partial_t^2 - \omega^2)$ would be a strongly divergent expression

$$\begin{aligned} \det(-\partial_t^2 - \omega^2) &= \prod_{m=1}^{\infty} (\nu_m^2 - \omega^2) \\ &= \prod_{m=1}^{\infty} (\nu_m^2) \prod_{m=1}^{\infty} \left[\frac{\nu_m^2 - \omega^2}{\nu_m^2} \right] = \prod_{m=1}^{\infty} \left[\frac{\pi^2 m^2}{(t_b - t_a)^2} \right] \times \frac{\sin \omega(t_b - t_a)}{\omega(t_b - t_a)}. \end{aligned} \quad (2.183)$$

Only *ratios* of determinants $-\nabla\bar{\nabla} - \omega^2$ with different ω 's can be replaced by their differential limits. Then the common divergent factor in (2.183) cancels.

Let us look at the origin of this strong divergence. The eigenvalues on the lattice and their continuum approximation start both out for small m as

$$\Omega_m \bar{\Omega}_m \approx \nu_m^2 \approx \frac{\pi^2 m^2}{(t_b - t_a)^2}. \quad (2.184)$$

For large $m \leq N$, the eigenvalues on the lattice saturate at $\Omega_m \bar{\Omega}_m \rightarrow 2/\epsilon^2$, while the ν_m^2 's keep growing quadratically in m . This causes the divergence.

The correct time-sliced formulas for the fluctuation factor of a harmonic oscillator is summarized by the following sequence of equations:

$$\begin{aligned} F_\omega^N(t_b - t_a) &= \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \prod_{n=1}^N \left[\int \frac{d\delta x_n}{\sqrt{2\pi\hbar i\epsilon/M}} \exp \left[\frac{i}{\hbar} \frac{M}{2\epsilon} \delta x^T (-\epsilon^2 \nabla\bar{\nabla} - \epsilon^2 \omega^2) \delta x \right] \right] \\ &= \frac{1}{\sqrt{2\pi\hbar i\epsilon/M}} \frac{1}{\sqrt{\det_N(-\epsilon^2 \nabla\bar{\nabla} - \epsilon^2 \omega^2)}}, \end{aligned} \quad (2.185)$$

where in the first expression, the exponent is written in matrix notation with x^T denoting the transposed vector x whose components are x_n . Taking out a free-particle determinant $\det_N(-\epsilon^2 \nabla\bar{\nabla})$, formula (2.140), leads to the ratio formula

$$F_\omega^N(t_b - t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \left[\frac{\det_N(-\epsilon^2 \nabla\bar{\nabla} - \epsilon^2 \omega^2)}{\det_N(-\epsilon^2 \nabla\bar{\nabla})} \right]^{-1/2}, \quad (2.186)$$

which yields

$$F_\omega^N(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\sin \tilde{\omega}\epsilon}{\epsilon \sin \tilde{\omega}(t_b - t_a)}}, \quad (2.187)$$

If with $\tilde{\omega}$ of Eq. (2.163). If we are only interested in the continuum limit, we may let ϵ go to zero on the right-hand side of (2.186) and evaluate

$$\begin{aligned} F_\omega(t_b - t_a) &= \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \left[\frac{\det(-\partial_t^2 - \omega^2)}{\det(-\partial_t^2)} \right]^{-1/2} \\ &= \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \prod_{m=1}^{\infty} \left[\frac{\nu_m^2 - \omega^2}{\nu_m^2} \right]^{-1/2} \\ &= \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \sqrt{\frac{\omega(t_b - t_a)}{\sin \omega(t_b - t_a)}}. \end{aligned} \quad (2.188)$$

Let us calculate also here the time evolution amplitude in momentum space. The Fourier transform of initial and final positions of (2.177) [as in (2.73)] yields

$$\begin{aligned} (\mathbf{p}_b t_b | \mathbf{p}_a t_a) &= \int d^D x_b e^{-i\mathbf{p}_b \mathbf{x}_b / \hbar} \int d^D x_a e^{i\mathbf{p}_a \mathbf{x}_a / \hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) \\ &= \frac{(2\pi\hbar)^D}{\sqrt{2\pi i \hbar}^D} \frac{1}{\sqrt{M\omega \sin \omega(t_b - t_a)}^D} \\ &\times \exp \left\{ \frac{i}{\hbar} \frac{1}{2M\omega \sin \omega(t_b - t_a)} [(\mathbf{p}_b^2 + \mathbf{p}_a^2) \cos \omega(t_b - t_a) - 2\mathbf{p}_b \mathbf{p}_a] \right\}. \end{aligned} \quad (2.189)$$

The limit $\omega \rightarrow 0$ reduces to the free-particle expression (2.73), not quite as directly as in the \mathbf{x} -space amplitude (2.177). Expanding the exponent

$$\begin{aligned} &\frac{1}{2M\omega \sin \omega(t_b - t_a)} [(\mathbf{p}_b^2 + \mathbf{p}_a^2) \cos \omega(t_b - t_a) - 2\mathbf{p}_b \mathbf{p}_a] \\ &= \frac{1}{2M\omega^2(t_b - t_a)} \left\{ (\mathbf{p}_b - \mathbf{p}_a)^2 - \frac{1}{2}(\mathbf{p}_b^2 + \mathbf{p}_a^2)[\omega(t_b - t_a)]^2 + \dots \right\}, \end{aligned} \quad (2.190)$$

and going to the limit $\omega \rightarrow 0$, the leading term in (2.189)

$$\frac{(2\pi)^D}{\sqrt{2\pi i \omega^2(t_b - t_a) \hbar M}^D} \exp \left\{ \frac{i}{\hbar} \frac{1}{2M\omega^2(t_b - t_a)} (\mathbf{p}_b - \mathbf{p}_a)^2 \right\} \quad (2.191)$$

tends to $(2\pi\hbar)^D \delta^{(D)}(\mathbf{p}_b - \mathbf{p}_a)$ [recall (1.534)], while the second term in (2.190) yields a factor $e^{-i\mathbf{p}^2(t_b - t_a)/2M\hbar}$, so that we recover indeed (2.73).

2.3.6 Oscillator Amplitude on Finite Time Lattice

Let us calculate the exact time evolution amplitude for a finite number of time slices. In contrast to the free-particle case in Section 2.2.5, the oscillator amplitude is no longer equal to its continuum limit but ϵ -dependent. This will allow us to study some typical convergence properties of path integrals in the continuum limit. Since the fluctuation factor was initially calculated at a finite ϵ in (2.169), we only need to find the classical action for finite ϵ . To maintain time reversal invariance at any finite ϵ , we work with a slightly different sliced potential term in the action than before in (2.148), using

$$\mathcal{A}^N = \epsilon \frac{M}{2} \sum_{n=1}^{N+1} [(\bar{\nabla} x_n)^2 - \omega^2(x_n^2 + x_{n-1}^2)/2], \quad (2.192)$$

or, written in another way,

$$\mathcal{A}^N = \epsilon \frac{M}{2} \sum_{n=0}^N [(\nabla x_n)^2 - \omega^2(x_{n+1}^2 + x_n^2)/2]. \quad (2.193)$$

This differs from the original time-sliced action (2.148) by having the potential $\omega^2 x_n^2$ replaced by the more symmetric one $\omega^2(x_n^2 + x_{n-1}^2)/2$. The gradient term is the same in both cases and can be rewritten, after a summation by parts, as

$$\epsilon \sum_{n=1}^{N+1} (\bar{\nabla} x_n)^2 = \epsilon \sum_{n=0}^N (\nabla x_n)^2 = [x_b \bar{\nabla} x_b - x_a \nabla x_a] - \epsilon \sum_{n=1}^N x_n \nabla \bar{\nabla} x_n. \quad (2.194)$$

This leads to a time-sliced action

$$\mathcal{A}^N = \frac{M}{2} (x_b \bar{\nabla} x_b - x_a \nabla x_a) - \epsilon \frac{M}{4} \omega^2 (x_b^2 + x_a^2) - \epsilon \frac{M}{2} \sum_{n=1}^N x_n (\nabla \bar{\nabla} + \omega^2) x_n. \quad (2.195)$$

Since the variation of \mathcal{A}^N is performed at fixed endpoints x_a and x_b , the fluctuation factor is the same as in (2.160). The equation of motion on the sliced time axis is

$$(\nabla \bar{\nabla} + \omega^2) x_{\text{cl}}(t) = 0. \quad (2.196)$$

Here it is understood that the time variable takes only the discrete lattice values t_n . The solution of this difference equation with the initial and final values x_a and x_b , respectively, is given by

$$x_{\text{cl}}(t) = \frac{1}{\sin \tilde{\omega}(t_b - t_a)} [x_b \sin \tilde{\omega}(t - t_a) + x_a \sin \tilde{\omega}(t_b - t)], \quad (2.197)$$

where $\tilde{\omega}$ is the auxiliary frequency introduced in (2.163). To calculate the classical action on the lattice, we insert (2.197) into (2.195). After some trigonometry, and replacing $\epsilon^2 \omega^2$ by $4 \sin^2(\tilde{\omega} \epsilon / 2)$, the action resembles closely the continuum expression (2.159):

$$\mathcal{A}_{\text{cl}}^N = \frac{M}{2\epsilon} \frac{\sin \tilde{\omega} \epsilon}{\sin \tilde{\omega}(t_b - t_a)} [(x_b^2 + x_a^2) \cos \tilde{\omega}(t_b - t_a) - 2x_b x_a]. \quad (2.198)$$

The total time evolution amplitude on the sliced time axis is

$$(x_b t_b | x_a t_a) = e^{i \mathcal{A}_{\text{cl}}^N / \hbar} F_{\omega}^N(t_b - t_a), \quad (2.199)$$

with sliced action (2.198) and the sliced fluctuation factor (2.169).

2.4 Gelfand-Yaglom Formula

In many applications one encounters a slight generalization of the oscillator fluctuation problem: The action is harmonic but contains a time-dependent frequency $\Omega^2(t)$ instead of the constant oscillator frequency ω^2 . The associated fluctuation factor is

$$F(t_b, t_a) = \int \mathcal{D}\delta x(t) \exp\left(\frac{i}{\hbar} \mathcal{A}\right), \quad (2.200)$$

with the action

$$\mathcal{A} = \int_{t_a}^{t_b} dt \frac{M}{2} [(\delta \dot{x})^2 - \Omega^2(t) (\delta x)^2]. \quad (2.201)$$

Since $\Omega(t)$ may not be translationally invariant in time, the fluctuation factor depends now in general on both the initial and final times. The ratio formula (2.186) holds also in this more general case, i.e.,

$$F^N(t_b, t_a) = \frac{1}{\sqrt{2\pi \hbar i (t_b - t_a) / M}} \left[\frac{\det_N(-\epsilon^2 \nabla \bar{\nabla} - \epsilon^2 \Omega^2)}{\det_N(-\epsilon^2 \nabla \bar{\nabla})} \right]^{-1/2}. \quad (2.202)$$

Here $\Omega^2(t)$ denotes the diagonal matrix

$$\Omega^2(t) = \begin{pmatrix} \Omega_N^2 & & \\ & \ddots & \\ & & \Omega_1^2 \end{pmatrix}, \quad (2.203)$$

with the matrix elements $\Omega_n^2 = \Omega^2(t_n)$.

2.4.1 Recursive Calculation of Fluctuation Determinant

In general, the full set of eigenvalues of the matrix $-\nabla\bar{\nabla} - \Omega^2(t)$ is quite difficult to find, even in the continuum limit. It is, however, possible to derive a powerful difference equation for the fluctuation determinant which can often be used to find its value without knowing all eigenvalues. The method is due to Gelfand and Yaglom.¹¹

Let us denote the determinant of the $N \times N$ fluctuation matrix by D_N , i.e.,

$$D_N \equiv \det_N \left(-\epsilon^2 \bar{\nabla} \nabla - \epsilon^2 \Omega^2 \right) \quad (2.204)$$

$$\equiv \begin{vmatrix} 2 - \epsilon^2 \Omega_N^2 & -1 & 0 & \dots & 0 & 0 & 0 \\ -1 & 2 - \epsilon^2 \Omega_{N-1}^2 & -1 & \dots & 0 & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & 0 & \dots & -1 & 2 - \epsilon^2 \Omega_2^2 & -1 \\ 0 & 0 & 0 & \dots & 0 & -1 & 2 - \epsilon^2 \Omega_1^2 \end{vmatrix}.$$

By expanding this along the first column, we obtain the recursion relation

$$D_N = (2 - \epsilon^2 \Omega_N^2) D_{N-1} - D_{N-2}, \quad (2.205)$$

which may be rewritten as

$$\epsilon^2 \left[\frac{1}{\epsilon} \left(\frac{D_N - D_{N-1}}{\epsilon} - \frac{D_{N-1} - D_{N-2}}{\epsilon} \right) + \Omega_N^2 D_{N-1} \right] = 0. \quad (2.206)$$

Since the equation is valid for all N , it implies that the determinant D_N satisfies the difference equation

$$(\nabla\bar{\nabla} + \Omega_{N+1}^2) D_N = 0. \quad (2.207)$$

In this notation, the operator $-\nabla\bar{\nabla}$ is understood to act on the dimensional label N of the determinant. The determinant D_N may be viewed as the discrete values of a function of $D(t)$ evaluated on the sliced time axis. Equation (2.207) is called the *Gelfand-Yaglom formula*. Thus the determinant as a function of N is the solution of the classical difference equation of motion and the desired result for a given N is obtained from the final value $D_N = D(t_{N+1})$. The initial conditions are

$$\begin{aligned} D_1 &= (2 - \epsilon^2 \Omega_1^2), \\ D_2 &= (2 - \epsilon^2 \Omega_1^2)(2 - \epsilon^2 \Omega_2^2) - 1. \end{aligned} \quad (2.208)$$

2.4.2 Examples

As an illustration of the power of the Gelfand-Yaglom formula, consider the known case of a constant $\Omega^2(t) \equiv \omega^2$ where the Gelfand-Yaglom formula reads

$$(\nabla\bar{\nabla} + \omega^2) D_N = 0. \quad (2.209)$$

This is solved by a linear combination of $\sin(N\tilde{\omega}\epsilon)$ and $\cos(N\tilde{\omega}\epsilon)$, where $\tilde{\omega}$ is given by (2.163). The solution satisfying the correct boundary condition is obviously

$$D_N = \frac{\sin(N+1)\epsilon\tilde{\omega}}{\sin\epsilon\tilde{\omega}}. \quad (2.210)$$

¹¹I.M. Gelfand and A.M. Yaglom, *J. Math. Phys.* 1, 48 (1960).

Figure 2.2 Solution of equation of motion with zero initial value and unit initial slope. Its value at the final time is equal to ϵ times the discrete fluctuation determinant $D_N = D(t_b)$.

Indeed, the two lowest elements are

$$\begin{aligned} D_1 &= 2 \cos \epsilon \tilde{\omega}, \\ D_2 &= 4 \cos^2 \epsilon \tilde{\omega} - 1, \end{aligned} \quad (2.211)$$

which are the same as (2.208), since $\epsilon^2 \Omega^2 \equiv \epsilon^2 \omega^2 = 2(1 - \cos \tilde{\omega} \epsilon)$.

The Gelfand-Yaglom formula becomes especially easy to handle in the continuum limit $\epsilon \rightarrow 0$. Then, by considering the renormalized function

$$D_{\text{ren}}(t_N) = \epsilon D_N, \quad (2.212)$$

the initial conditions $D_1 = 2$ and $D_2 = 3$ can be re-expressed as

$$(\epsilon D)_1 = D_{\text{ren}}(t_a) = 0, \quad (2.213)$$

$$\frac{\epsilon D_2 - \epsilon D_1}{\epsilon} = (\nabla \epsilon D)_1 \xrightarrow{\epsilon \rightarrow 0} \dot{D}_{\text{ren}}(t_a) = 1. \quad (2.214)$$

The difference equation for D_N turns into the differential equation for $D_{\text{ren}}(t)$:

$$[\partial_t^2 + \Omega^2(t)] D_{\text{ren}}(t) = 0. \quad (2.215)$$

The situation is pictured in Fig. 2.2. The determinant D_N is $1/\epsilon$ times the value of the function $D_{\text{ren}}(t)$ at t_b . This value is found by solving the differential equation starting from t_a with zero value and unit slope.

As an example, consider once more the harmonic oscillator with a fixed frequency ω . The equation of motion in the continuum limit is solved by

$$D_{\text{ren}}(t) = \frac{1}{\omega} \sin \omega(t - t_a), \quad (2.216)$$

which satisfies the initial conditions (2.214). Thus we find the fluctuation determinant to become, for small ϵ ,

$$\det(-\epsilon^2 \nabla \overline{\nabla} - \epsilon^2 \omega^2) \xrightarrow{\epsilon \rightarrow 0} \frac{1}{\epsilon} \frac{\sin \omega(t_b - t_a)}{\omega}, \quad (2.217)$$

in agreement with the earlier result (2.210). For the free particle, the solution is $D_{\text{ren}}(t) = t - t_a$ and we obtain directly the determinant $\det_N(-\epsilon^2 \nabla \overline{\nabla}) = (t_b - t_a)/\epsilon$.

For time-dependent frequencies $\Omega(t)$, an analytic solution of the Gelfand-Yaglom initial-value problem (2.213), (2.214), and (2.215) can be found only for special classes of functions $\Omega(t)$. In fact, (2.215) has the form of a Schrödinger equation of a point particle in a potential $\Omega^2(t)$, and the classes of potentials for which the Schrödinger equation can be solved are well-known.

2.4.3 Calculation on Unsliced Time Axis

In general, the most explicit way of expressing the solution is by linearly combining $D_{\text{ren}} = \epsilon D_N$ from any two independent solutions $\xi(t)$ and $\eta(t)$ of the homogeneous differential equation

$$[\partial_t^2 + \Omega^2(t)]x(t) = 0. \quad (2.218)$$

The solution of (2.215) is found from a linear combination

$$D_{\text{ren}}(t) = \alpha\xi(t) + \beta\eta(t). \quad (2.219)$$

The coefficients are determined from the initial condition (2.214), which imply

$$\begin{aligned} \alpha\xi(t_a) + \beta\eta(t_a) &= 0, \\ \alpha\dot{\xi}(t_a) + \beta\dot{\eta}(t_a) &= 1, \end{aligned} \quad (2.220)$$

and thus

$$D_{\text{ren}}(t) = \frac{\xi(t)\eta(t_a) - \xi(t_a)\eta(t)}{\xi(t_a)\eta(t_a) - \xi(t_a)\dot{\eta}(t_a)}. \quad (2.221)$$

The denominator is recognized as the time-independent *Wronski determinant* of the two solutions

$$W \equiv \xi(t) \overleftrightarrow{\partial}_t \eta(t) \equiv \xi(t)\dot{\eta}(t) - \dot{\xi}(t)\eta(t) \quad (2.222)$$

at the initial point t_a . The right-hand side is independent of t .

The Wronskian is an important quantity in the theory of second-order differential equations. It is defined for all equations of the Sturm-Liouville type

$$\frac{d}{dt} \left[a(t) \frac{dy(t)}{dt} \right] + b(t)y(t) = 0, \quad (2.223)$$

for which it is proportional to $1/a(t)$. The Wronskian is used to construct the Green function for all such equations.¹²

In terms of the Wronskian, Eq. (2.221) has the general form

$$D_{\text{ren}}(t) = -\frac{1}{W} [\xi(t)\eta(t_a) - \xi(t_a)\eta(t)]. \quad (2.224)$$

Inserting $t = t_b$ gives the desired determinant

$$D_{\text{ren}} = -\frac{1}{W} [\xi(t_b)\eta(t_a) - \xi(t_a)\eta(t_b)]. \quad (2.225)$$

Note that the same functional determinant can be found from by evaluating the function

$$\tilde{D}_{\text{ren}}(t) = -\frac{1}{W} [\xi(t_b)\eta(t) - \xi(t)\eta(t_b)] \quad (2.226)$$

¹²For its typical use in classical electrodynamics, see J.D. Jackson, *Classical Electrodynamics*, John Wiley & Sons, New York, 1975, Section 3.11.

at t_a . This also satisfies the homogenous differential equation (2.215), but with the initial conditions

$$\tilde{D}_{\text{ren}}(t_b) = 0, \quad \dot{\tilde{D}}_{\text{ren}}(t_b) = -1. \quad (2.227)$$

It will be useful to emphasize at which ends the Gelfand-Yaglom boundary conditions are satisfied by denoting $D_{\text{ren}}(t)$ and $\tilde{D}_{\text{ren}}(t)$ by $D_a(t)$ and $D_b(t)$, respectively, summarizing their symmetric properties as

$$[\partial_t^2 + \Omega^2(t)]D_a(t) = 0; \quad D_a(t_a) = 0, \quad \dot{D}_a(t_a) = 1, \quad (2.228)$$

$$[\partial_t^2 + \Omega^2(t)]D_b(t) = 0; \quad D_b(t_b) = 0, \quad \dot{D}_b(t_b) = -1, \quad (2.229)$$

with the determinant being obtained from either function as

$$D_{\text{ren}} = D_a(t_b) = D_b(t_a). \quad (2.230)$$

In contrast to this we see from the explicit equations (2.224) and (2.226) that the time derivatives of two functions at opposite endpoints are in general not related. Only for frequencies $\Omega(t)$ with time reversal invariance, one has

$$\dot{D}_a(t_b) = -\dot{D}_b(t_a), \quad \text{for } \Omega(t) = \Omega(-t). \quad (2.231)$$

For arbitrary $\Omega(t)$, one can derive a relation

$$\dot{D}_a(t_b) + \dot{D}_b(t_a) = -2 \int_{t_a}^{t_b} dt \Omega(t) \dot{\Omega}(t) D_a(t) D_b(t). \quad (2.232)$$

As an application of these formulas, consider once more the linear oscillator, for which two independent solutions are

$$\xi(t) = \cos \omega t, \quad \eta(t) = \sin \omega t. \quad (2.233)$$

Hence

$$W = \omega, \quad (2.234)$$

and the fluctuation determinant becomes

$$D_{\text{ren}} = -\frac{1}{\omega} (\cos \omega t_b \sin \omega t_a - \cos \omega t_a \sin \omega t_b) = \frac{1}{\omega} \sin \omega (t_b - t_a). \quad (2.235)$$

2.4.4 D'Alembert's Construction

It is important to realize that the construction of the solutions of Eqs. (2.228) and (2.229) requires only the knowledge of one solution of the homogenous differential equation (2.218), say $\xi(t)$. A second linearly independent solution $\eta(t)$ can always be found with the help of a formula due to d'Alembert,

$$\eta(t) = w \xi(t) \int \frac{dt'}{\xi^2(t')}, \quad (2.236)$$

where w is some constant. Differentiation yields

$$\dot{\eta} = \frac{\dot{\xi}\eta}{\xi} + \frac{w}{\xi}, \quad \ddot{\eta} = \frac{\ddot{\xi}\eta}{\xi}. \quad (2.237)$$

The second equation shows that with $\xi(t)$, also $\eta(t)$ is a solution of the homogenous differential equation (2.218). From the first equation we find that the Wronski determinant of the two functions is equal to w :

$$W = \xi(t)\dot{\eta}(t) - \dot{\xi}(t)\eta(t) = w. \quad (2.238)$$

Inserting the solution (2.236) into the formulas (2.224) and (2.226), we obtain explicit expressions for the Gelfand-Yaglom functions in terms of one arbitrary solution of the homogenous differential equation (2.218):

$$D_{\text{ren}}(t) = D_a(t) = \xi(t)\xi(t_a) \int_{t_a}^t \frac{dt'}{\xi^2(t')}, \quad \tilde{D}_{\text{ren}}(t) = D_b(t) = \xi(t_b)\xi(t) \int_t^{t_b} \frac{dt'}{\xi^2(t')}. \quad (2.239)$$

The desired functional determinant is

$$D_{\text{ren}} = \xi(t_b)\xi(t_a) \int_{t_a}^{t_b} \frac{dt'}{\xi^2(t')}. \quad (2.240)$$

2.4.5 Another Simple Formula

There exists yet another useful formula for the functional determinant. For this we solve the homogenous differential equation (2.218) for an arbitrary initial position x_a and initial velocity \dot{x}_a at the time t_a . The result may be expressed as the following linear combination of $D_a(t)$ and $D_b(t)$:

$$x(x_a, \dot{x}_a; t) = \frac{1}{D_b(t_a)} \left[D_b(t) - D_a(t)\dot{D}_b(t_a) \right] x_a + D_a(t)\dot{x}_a. \quad (2.241)$$

We then see that the Gelfand-Yaglom function $D_{\text{ren}}(t) = D_a(t)$ can be obtained from the partial derivative

$$D_{\text{ren}}(t) = \frac{\partial x(x_a, \dot{x}_a; t)}{\partial \dot{x}_a}. \quad (2.242)$$

This function obviously satisfies the Gelfand-Yaglom initial conditions $D_{\text{ren}}(t_a) = 0$ and $\dot{D}_{\text{ren}}(t_a) = 1$ of (2.213) and (2.214), which are a direct consequence of the fact that x_a and \dot{x}_a are independent variables in the function $x(x_a, \dot{x}_a; t)$, for which $\partial x_a / \partial \dot{x}_a = 0$ and $\partial \dot{x}_a / \partial \dot{x}_a = 1$.

The fluctuation determinant $D_{\text{ren}} = D_a(t_b)$ is then given by

$$D_{\text{ren}} = \frac{\partial x_b}{\partial \dot{x}_a}, \quad (2.243)$$

where x_b abbreviates the function $x(x_a, \dot{x}_a; t_b)$. It is now obvious that the analogous equations (2.229) are satisfied by the partial derivative $D_b(t) = -\partial x(t) / \partial \dot{x}_b$, where $x(t)$ is expressed in terms of the final position x_b and velocity \dot{x}_b as $x(t) = x(x_b, \dot{x}_b; t)$

$$x(x_b, \dot{x}_b; t) = \frac{1}{D_a(t_b)} \left[D_a(t) + D_b(t)\dot{D}_a(t_b) \right] x_b - D_b(t)\dot{x}_b, \quad (2.244)$$

so that we obtain the alternative formula

$$D_{\text{ren}} = -\frac{\partial x_a}{\partial \dot{x}_b}. \quad (2.245)$$

These results can immediately be generalized to functional determinants of differential operators of the form $-\partial_t^2 \delta_{ij} - \Omega_{ij}^2(t)$ where the time-dependent frequency is a $D \times D$ -dimensional matrix $\Omega_{ij}^2(t)$, ($i, j = 1, \dots, D$). Then the associated Gelfand-Yaglom function $D_a(t)$ becomes a matrix $D_{ij}(t)$ satisfying the initial conditions $D_{ij}(t_a) = 0$, $\dot{D}_{ij}(t_b) = \delta_{ij}$, and the desired functional determinant D_{ren} is equal to the ordinary determinant of $D_{ij}(t_b)$:

$$D_{\text{ren}} = \text{Det} [-\partial_t^2 \delta_{ij} - \Omega_{ij}^2(t)] = \det D_{ij}(t_b). \quad (2.246)$$

The homogeneous differential equation and the initial conditions are obviously satisfied by the partial derivative matrix $D_{ij}(t) = \partial x^i(t)/\partial \dot{x}_a^j$, so that the explicit representations of $D_{ij}(t)$ in terms of the general solution of the classical equations of motion $[-\partial_t^2 \delta_{ij} - \Omega_{ij}^2(t)] x_j(t) = 0$ become

$$D_{\text{ren}} = \det \frac{\partial x_b^i}{\partial \dot{x}_a^j} = \det \left(-\frac{\partial x_a^i}{\partial \dot{x}_b^j} \right). \quad (2.247)$$

A further couple of formulas for functional determinants can be found by constructing a solution of the homogeneous differential equation (2.218) which passes through specific initial and final points x_a and x_b at t_a and t_b , respectively:

$$x(x_b, x_a; t) = \frac{D_b(t)}{D_b(t_a)} x_a + \frac{D_a(t)}{D_a(t_b)} x_b. \quad (2.248)$$

The Gelfand-Yaglom functions $D_a(t)$ and $D_b(t)$ can therefore be obtained from the partial derivatives

$$\frac{D_a(t)}{D_a(t_b)} = \frac{\partial x(x_b, x_a; t)}{\partial x_b}, \quad \frac{D_b(t)}{D_b(t_a)} = \frac{\partial x(x_b, x_a; t)}{\partial x_a}. \quad (2.249)$$

At the endpoints, Eqs. (2.248) yield

$$\dot{x}_a = \frac{\dot{D}_b(t_a)}{D_b(t_a)} x_a + \frac{1}{D_a(t_b)} x_b, \quad (2.250)$$

$$\dot{x}_b = -\frac{1}{D_b(t_a)} x_a + \frac{\dot{D}_a(t_b)}{D_a(t_b)} x_b, \quad (2.251)$$

so that the fluctuation determinant $D_{\text{ren}} = D_a(t_b) = D_b(t_a)$ is given by the formulas

$$D_{\text{ren}} = \left(\frac{\partial \dot{x}_a}{\partial x_b} \right)^{-1} = - \left(\frac{\partial \dot{x}_b}{\partial x_a} \right)^{-1}, \quad (2.252)$$

where \dot{x}_a and \dot{x}_b are functions of the independent variables x_a and x_b . The equality of these expressions with the previous ones in (2.243) and (2.245) is a direct consequence of the mathematical identity for partial derivatives

$$\left. \frac{\partial x_b}{\partial \dot{x}_a} \right|_{x_a} = \left(\left. \frac{\partial \dot{x}_a}{\partial x_b} \right|_{x_a} \right)^{-1}. \quad (2.253)$$

Let us emphasize that all functional determinants calculated in this Chapter apply to the fluctuation factor of paths with fixed endpoints. In mathematics, this property is referred to as Dirichlet boundary conditions. In the context of quantum statistics, we shall also need such determinants for fluctuations with periodic boundary conditions, for which the Gelfand-Yaglom method must be modified. We shall see in Section 2.11 that this causes considerable complications

in the lattice derivation, which will make it desirable to find a simpler derivation of both functional determinants. This will be found in Section 3.27 in a continuum formulation.

In general, the homogenous differential equation (2.218) with time-dependent frequency $\Omega(t)$ cannot be solved analytically. The equation has the same form as a Schrödinger equation for a point particle in one dimension moving in a one dimensional potential $\Omega^2(t)$, and there are only a few classes of potentials for which the solutions are known in closed form. Fortunately, however, the functional determinant will usually arise in the context of quadratic fluctuations around classical solutions in time-independent potentials (see in Section 4.3). If such a classical solution is known analytically, it will provide us automatically with a solution of the homogeneous differential equation (2.218). Some important examples will be discussed in Sections 17.4 and 17.11.

2.4.6 Generalization to D Dimensions

The above formulas have an obvious generalization to a D -dimensional version of the fluctuation action (2.201)

$$\mathcal{A} = \int_{t_a}^{t_b} dt \frac{M}{2} [(\delta\dot{\mathbf{x}})^2 - \delta\mathbf{x}^T \boldsymbol{\Omega}^2(t) \delta\mathbf{x}], \quad (2.254)$$

where $\boldsymbol{\Omega}^2(t)$ is a $D \times D$ matrix with elements $\Omega_{ij}^2(t)$. The fluctuation factor (2.202) generalizes to

$$F^N(t_b, t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}^D} \left[\frac{\det_N(-\epsilon^2 \nabla \bar{\nabla} - \epsilon^2 \boldsymbol{\Omega}^2)}{\det_N(-\epsilon^2 \nabla \bar{\nabla})} \right]^{-1/2}. \quad (2.255)$$

The fluctuation determinant is found by Gelfand-Yaglom's construction from a formula

$$D_{\text{ren}} = \det \mathbf{D}_a(t_b) = \det \mathbf{D}_b(t_a), \quad (2.256)$$

with the matrices $\mathbf{D}_a(t)$ and $\mathbf{D}_b(t)$ satisfying the classical equations of motion and initial conditions corresponding to (2.228) and (2.229):

$$[\partial_t^2 + \boldsymbol{\Omega}^2(t)] \mathbf{D}_a(t) = 0; \quad \mathbf{D}_a(t_a) = 0, \quad \dot{\mathbf{D}}_a(t_a) = \mathbf{1}, \quad (2.257)$$

$$[\partial_t^2 + \boldsymbol{\Omega}^2(t)] \mathbf{D}_b(t) = 0; \quad \mathbf{D}_b(t_b) = 0, \quad \dot{\mathbf{D}}_b(t_b) = -\mathbf{1}, \quad (2.258)$$

where $\mathbf{1}$ is the unit matrix in D dimensions. We can then repeat all steps in the last section and find the D -dimensional generalization of formulas (2.252):

$$D_{\text{ren}} = \left(\det \frac{\partial \dot{x}_a^i}{\partial x_b^j} \right)^{-1} = \left[\det \left(-\frac{\partial \dot{x}_b^i}{\partial x_a^j} \right) \right]^{-1}. \quad (2.259)$$

2.5 Harmonic Oscillator with Time-Dependent Frequency

The results of the last section put us in a position to solve exactly the path integral of a harmonic oscillator with arbitrary time-dependent frequency $\Omega(t)$. We shall first do this in coordinate space, later in momentum space.

2.5.1 Coordinate Space

Consider the path integral

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x \exp \left\{ \frac{i}{\hbar} \mathcal{A}[x] \right\}, \quad (2.260)$$

with the Lagrangian action

$$\mathcal{A}[x] = \frac{M}{2} \int_{t_a}^{t_b} dt \left[\dot{x}^2(t) - \Omega^2(t)x^2(t) \right], \quad (2.261)$$

which is harmonic with a time-dependent frequency. As in Eq. (2.14), the result can be written as a product of a fluctuation factor and an exponential containing the classical action:

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x e^{i\mathcal{A}[x]/\hbar} = F_\Omega(t_b, t_a) e^{i\mathcal{A}_{\text{cl}}/\hbar}. \quad (2.262)$$

From the discussion in the last section we know that the fluctuation factor is, by analogy with (2.171), and recalling (2.243),

$$F_\Omega(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \frac{1}{\sqrt{D_a(t_b)}}. \quad (2.263)$$

The determinant $D_a(t_b) = D_{\text{ren}}$ may be expressed in terms of partial derivatives according to formulas (2.243) and (2.252):

$$F_\Omega(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \left(\frac{\partial x_b}{\partial \dot{x}_a} \right)^{-1/2} = \frac{1}{\sqrt{2\pi i \hbar / M}} \left(\frac{\partial \dot{x}_a}{\partial x_b} \right)^{1/2}, \quad (2.264)$$

where the first partial derivative is calculated from the function $x(x_a, \dot{x}_a; t)$, the second from $\dot{x}(x_b, x_a; t)$. Equivalently we may use (2.245) and the right-hand part of Eq. (2.252) to write

$$F_\Omega(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \left(-\frac{\partial x_a}{\partial \dot{x}_b} \right)^{-1/2} = \frac{1}{\sqrt{2\pi i \hbar / M}} \left(-\frac{\partial \dot{x}_b}{\partial x_a} \right)^{1/2}. \quad (2.265)$$

It remains to calculate the classical action \mathcal{A}_{cl} . This can be done in the same way as in Eqs. (2.155) to (2.159). After a partial integration, we have as before

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} (x_b \dot{x}_b - x_a \dot{x}_a). \quad (2.266)$$

Exploiting the linear dependence of \dot{x}_b and \dot{x}_a on the endpoints x_b and x_a , we may rewrite this as

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} \left(x_b \frac{\partial \dot{x}_b}{\partial x_b} x_b - x_a \frac{\partial \dot{x}_a}{\partial x_a} x_a + x_b \frac{\partial \dot{x}_b}{\partial x_a} x_a - x_a \frac{\partial \dot{x}_a}{\partial x_b} x_b \right). \quad (2.267)$$

Inserting the partial derivatives from (2.250) and (2.251) and using the equality of $D_a(t_b)$ and $D_b(t_a)$, we obtain the classical action

$$\mathcal{A}_{\text{cl}} = \frac{M}{2D_a(t_b)} \left[x_b^2 \dot{D}_a(t_b) - x_a^2 \dot{D}_b(t_a) - 2x_b x_a \right]. \quad (2.268)$$

Note that there exists another simple formula for the fluctuation determinant D_{ren} :

$$D_{\text{ren}} = D_a(t_b) = D_b(t_a) = -M \left(\frac{\partial^2}{\partial x_b \partial x_a} \mathcal{A}_{\text{cl}} \right)^{-1}. \quad (2.269)$$

For the harmonic oscillator with time-independent frequency ω , the Gelfand-Yaglom function $D_a(t)$ of Eq. (2.235) has the property (2.231) due to time reversal invariance, and (2.268) reproduces the known result (2.159).

The expressions containing partial derivatives are easily extended to D dimensions: We simply have to replace the partial derivatives $\partial x_b / \partial x_a$, $\partial \dot{x}_b / \partial \dot{x}_a, \dots$ by the corresponding $D \times D$ matrices, and write the action as the associated quadratic form.

The D -dimensional versions of the fluctuation factors (2.264) are

$$F_{\Omega}(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}^D} \left[\det \frac{\partial x_b^i}{\partial \dot{x}_a^j} \right]^{-1/2} = \frac{1}{\sqrt{2\pi i \hbar / M}^D} \left[\det \frac{\partial \dot{x}_a^i}{\partial x_b^j} \right]^{1/2}. \quad (2.270)$$

All formulas for fluctuation factors hold initially only for sufficiently short times $t_b - t_a$. For larger times, they carry phase factors determined as before in (2.169). The fully defined expression may be written as

$$F_{\Omega}(t_b, t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}^D} \left| \det \frac{\partial x_b^i}{\partial \dot{x}_a^j} \right|^{-1/2} e^{-i\nu\pi/2} = \frac{1}{\sqrt{2\pi i \hbar / M}^D} \left| \det \frac{\partial \dot{x}_a^i}{\partial x_b^j} \right|^{1/2} e^{-i\nu\pi/2}, \quad (2.271)$$

where ν is the Maslov-Morse index. In the one-dimensional case it counts the turning points of the trajectory, in the multidimensional case the number of zeros in determinant $\det \partial x_b^i / \partial \dot{x}_a^j$ along the trajectory, if the zero is caused by a reduction of the rank of the matrix $\partial x_b^i / \partial \dot{x}_a^j$ by one unit. If it is reduced by more than one unit, ν increases accordingly. In this context, the number ν is also called the *Morse index* of the trajectory.

The zeros of the functional determinant are also called *conjugate points*. They are generalizations of the turning points in one-dimensional systems. The surfaces in \mathbf{x} -space, on which the determinant vanishes, are called *caustics*. The conjugate points are the places where the orbits touch the caustics.¹³

Note that for infinitesimally short times, all fluctuation factors and classical actions coincide with those of a free particle. This is obvious for the time-independent harmonic oscillator, where the amplitude (2.177) reduces to that of a free particle

¹³See M.C. Gutzwiller, *Chaos in Classical and Quantum Mechanics*, Springer, Berlin, 1990.

in Eq. (2.74) in the limit $t_b \rightarrow t_a$. Since a time-dependent frequency is constant over an infinitesimal time, this same result holds also here. Expanding the solution of the equations of motion for infinitesimally short times as

$$\mathbf{x}_b \approx (t_b - t_a)\dot{\mathbf{x}}_a + \mathbf{x}_a, \quad \mathbf{x}_a \approx -(t_b - t_a)\dot{\mathbf{x}}_b + \mathbf{x}_b, \quad (2.272)$$

we have immediately

$$\frac{\partial x_b^i}{\partial x_a^j} = \delta_{ij}(t_b - t_a), \quad \frac{\partial x_a^i}{\partial x_b^j} = -\delta_{ij}(t_b - t_a). \quad (2.273)$$

Similarly, the expansions

$$\dot{\mathbf{x}}_b \approx \dot{\mathbf{x}}_a \approx \frac{\mathbf{x}_b - \mathbf{x}_a}{t_b - t_a} \quad (2.274)$$

lead to

$$\frac{\partial \dot{x}_b^i}{\partial x_a^j} = -\delta_{ij} \frac{1}{t_b - t_a}, \quad \frac{\partial \dot{x}_a^i}{\partial x_b^j} = \delta_{ij} \frac{1}{t_b - t_a}. \quad (2.275)$$

Inserting the expansions (2.273) or (2.274) into (2.266) (in D dimensions), the action reduces approximately to the free-particle action

$$\mathcal{A}_{\text{cl}} \approx \frac{M}{2} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a}. \quad (2.276)$$

2.5.2 Momentum Space

Let us also find the time evolution amplitude in momentum space. For this we write the classical action (2.267) as a quadratic form

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} (x_b, x_a) A \begin{pmatrix} x_b \\ x_a \end{pmatrix} \quad (2.277)$$

with a matrix

$$A = \begin{pmatrix} \frac{\partial \dot{x}_b}{\partial x_b} & \frac{\partial \dot{x}_b}{\partial x_a} \\ -\frac{\partial \dot{x}_a}{\partial x_b} & -\frac{\partial \dot{x}_a}{\partial x_a} \end{pmatrix}. \quad (2.278)$$

The inverse of this matrix is

$$A^{-1} = \begin{pmatrix} \frac{\partial x_b}{\partial \dot{x}_b} & -\frac{\partial x_b}{\partial \dot{x}_a} \\ \frac{\partial x_a}{\partial \dot{x}_b} & -\frac{\partial x_a}{\partial \dot{x}_a} \end{pmatrix}. \quad (2.279)$$

The partial derivatives of x_b and x_a are calculated from the solution of the homogeneous differential equation (2.218) specified in terms of the final and initial velocities \dot{x}_b and \dot{x}_a :

$$x(\dot{x}_b, \dot{x}_a; t) = \frac{1}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1} \times \left\{ \left[D_a(t) + D_b(t)\dot{D}_a(t_b) \right] \dot{x}_a + \left[-D_b(t) + D_a(t)\dot{D}_b(t_a) \right] \dot{x}_b \right\}, \quad (2.280)$$

which yields

$$x_a = \frac{1}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1} \left[D_b(t_a)\dot{D}_a(t_a)\dot{x}_b - D_b(t_a)\dot{x}_b \right], \quad (2.281)$$

$$x_b = \frac{1}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1} \left[D_a(t_b)\dot{x}_a + D_a(t_b)\dot{D}_b(t_a)\dot{x}_b \right], \quad (2.282)$$

so that

$$A^{-1} = \frac{D_a(t_b)}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1} \begin{pmatrix} \dot{D}_b(t_a) & -1 \\ -1 & -\dot{D}_a(t_b) \end{pmatrix}. \quad (2.283)$$

The determinant of A is the Jacobian

$$\det A = -\frac{\partial(\dot{x}_b, \dot{x}_a)}{\partial(x_b, x_a)} = -\frac{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1}{D_a(t_b)D_b(t_a)}. \quad (2.284)$$

We can now perform the Fourier transform of the time evolution amplitude and find, via a quadratic completion,

$$\begin{aligned} (p_b t_b | p_a t_a) &= \int dx_b e^{-ip_b x_b / \hbar} \int dx_a e^{ip_a x_a / \hbar} (x_b t_b | x_a t_a) \\ &= \sqrt{\frac{2\pi\hbar}{iM}} \sqrt{\frac{D_a(t_b)}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1}} \\ &\times \exp \left\{ \frac{i}{\hbar} \frac{1}{2M} \frac{D_a(t_b)}{\dot{D}_a(t_b)\dot{D}_b(t_a) + 1} \left[-\dot{D}_b(t_a)p_b^2 + \dot{D}_a(t_b)p_a^2 - 2p_b p_a \right] \right\}. \end{aligned} \quad (2.285)$$

Inserting here $D_a(t_b) = \sin \omega(t_b - t_a)/\omega$ and $\dot{D}_a(t_b) = \cos \omega(t_b - t_a)$, we recover the oscillator result (2.189).

In D dimensions, the classical action has the same quadratic form as in (2.277)

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} (\mathbf{x}_b^T, \mathbf{x}_a^T) \mathbf{A} \begin{pmatrix} \mathbf{x}_b \\ \mathbf{x}_a \end{pmatrix} \quad (2.286)$$

with a matrix \mathbf{A} generalizing (2.278) by having the partial derivatives replaced by the corresponding $D \times D$ -matrices. The inverse is the $2D \times 2D$ -version of (2.279), i.e.

$$\mathbf{A} = \begin{pmatrix} \frac{\partial \dot{\mathbf{x}}_b}{\partial \mathbf{x}_b} & \frac{\partial \dot{\mathbf{x}}_b}{\partial \mathbf{x}_a} \\ -\frac{\partial \dot{\mathbf{x}}_a}{\partial \mathbf{x}_b} & -\frac{\partial \dot{\mathbf{x}}_a}{\partial \mathbf{x}_a} \end{pmatrix}, \quad \mathbf{A}^{-1} = \begin{pmatrix} \frac{\partial \mathbf{x}_b}{\partial \dot{\mathbf{x}}_b} & -\frac{\partial \mathbf{x}_b}{\partial \dot{\mathbf{x}}_a} \\ \frac{\partial \mathbf{x}_a}{\partial \dot{\mathbf{x}}_b} & -\frac{\partial \mathbf{x}_a}{\partial \dot{\mathbf{x}}_a} \end{pmatrix}. \quad (2.287)$$

The determinant of such a block matrix

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \quad (2.288)$$

is calculated after a triangular decomposition

$$\mathbf{A} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a & 0 \\ c & 1 \end{pmatrix} \begin{pmatrix} 1 & a^{-1}b \\ 0 & d - ca^{-1}b \end{pmatrix} = \begin{pmatrix} 1 & b \\ 0 & d \end{pmatrix} \begin{pmatrix} a - bd^{-1}c & 0 \\ d^{-1}c & 1 \end{pmatrix} \quad (2.289)$$

in two possible ways as

$$\det \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \det a \cdot \det (d - ca^{-1}b) = \det (a - bd^{-1}c) \cdot \det d, \quad (2.290)$$

depending whether $\det a$ or $\det b$ is nonzero. The inverse is in the first case

$$\mathbf{A} = \begin{pmatrix} 1 & -a^{-1}bx \\ 0 & x \end{pmatrix} \begin{pmatrix} a^{-1} & 0 \\ -ca^{-1} & 1 \end{pmatrix} = \begin{pmatrix} a^{-1} + a^{-1}bxca^{-1} - a^{-1}bx & \\ -xca^{-1} & x \end{pmatrix}, \quad x \equiv (d - ca^{-1}b)^{-1}. \quad (2.291)$$

The resulting amplitude in momentum space is

$$\begin{aligned} (\mathbf{p}_b t_b | \mathbf{p}_a t_a) &= \int dx_b e^{-i\mathbf{p}_b \mathbf{x}_b / \hbar} \int dx_a e^{i\mathbf{p}_a \mathbf{x}_a / \hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) \\ &= \frac{2\pi}{\sqrt{2\pi i \hbar M}} \frac{1}{\sqrt{D_{\text{ren}} \det \mathbf{A}}} \exp \left\{ \frac{i}{\hbar} \frac{1}{2M} \left[(\mathbf{p}_b^T, \mathbf{p}_a^T) \mathbf{A}^{-1} \begin{pmatrix} \mathbf{p}_b \\ \mathbf{p}_a \end{pmatrix} \right] \right\}. \end{aligned} \quad (2.292)$$

Also in momentum space, the amplitude (2.292) reduces to the free-particle one in Eq. (2.73) in the limit of infinitesimally short time $t_b - t_a$: For the time-independent harmonic oscillator, this was shown in Eq. (2.191), and the time-dependence of $\Omega(t)$ becomes irrelevant in the limit of small $t_b - t_a \rightarrow 0$.

2.6 Free-Particle and Oscillator Wave Functions

In Eq. (1.335) we have expressed the time evolution amplitude of the free particle (2.72) as a Fourier integral

$$(x_b t_b | x_a t_a) = \int \frac{dp}{(2\pi\hbar)} e^{ip(x_b - x_a)/\hbar} e^{-ip^2(t_b - t_a)/2M\hbar}. \quad (2.293)$$

This expression contains the information on all stationary states of the system. To find these states we have to perform a spectral analysis of the amplitude. Recall that according to Section 1.7, the amplitude of an arbitrary time-independent system possesses a spectral representation of the form

$$(x_b t_b | x_a t_a) = \sum_{n=0}^{\infty} \psi_n(x_b) \psi_n^*(x_a) e^{-iE_n(t_b - t_a)/\hbar}, \quad (2.294)$$

where E_n are the eigenvalues and $\psi_n(x)$ the wave functions of the stationary states. In the free-particle case the spectrum is continuous and the spectral sum is an integral. Comparing (2.294) with (2.293) we see that the Fourier decomposition itself happens to be the spectral representation. If the sum over n is written as an integral over the momenta, we can identify the wave functions as

$$\psi_p(x) = \frac{1}{\sqrt{2\pi\hbar}} e^{ipx}. \quad (2.295)$$

For the time evolution amplitude of the harmonic oscillator

$$\begin{aligned} (x_b t_b | x_a t_a) &= \frac{1}{\sqrt{2\pi i \hbar \sin[\omega(t_b - t_a)] / M\omega}} \\ &\times \exp \left\{ \frac{iM\omega}{2\hbar \sin[\omega(t_b - t_a)]} \left[(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a \right] \right\}, \end{aligned} \quad (2.296)$$

the procedure is not as straight-forward. Here we must make use of a summation formula for *Hermite polynomials* (see Appendix 2C) $H_n(x)$ due to Mehler:¹⁴

$$\begin{aligned} \frac{1}{\sqrt{1-a^2}} \exp \left\{ -\frac{1}{2(1-a^2)} [(x^2 + x'^2)(1+a^2) - 4xx'a] \right\} \\ = \exp(-x^2/2 - x'^2/2) \sum_{n=0}^{\infty} \frac{a^n}{2^n n!} H_n(x) H_n(x'), \end{aligned} \quad (2.297)$$

with

$$H_0(x) = 1, \quad H_1(x) = 2x, \quad H_2(x) = 4x^2 - 2, \dots, \quad H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}. \quad (2.298)$$

Identifying

$$x \equiv \sqrt{M\omega/\hbar} x_b, \quad x' \equiv \sqrt{M\omega/\hbar} x_a, \quad a \equiv e^{-i\omega(t_b-t_a)}, \quad (2.299)$$

so that

$$\frac{a}{1-a^2} = \frac{1}{2i \sin[\omega(t_b-t_a)]}, \quad \frac{1+a^2}{1-a^2} = \frac{1+e^{-2i\omega(t_b-t_a)}}{1-e^{-2i\omega(t_b-t_a)}} = \frac{\cos[\omega(t_b-t_a)]}{i \sin[\omega(t_b-t_a)]}$$

we arrive at the spectral representation

$$(x_b t_b | x_a t_a) = \sum_{n=0}^{\infty} \psi_n(x_b) \psi_n(x_a) e^{-i(n+1/2)\omega(t_b-t_a)}. \quad (2.300)$$

From this we deduce that the harmonic oscillator has the energy eigenvalues

$$E_n = \hbar\omega(n + 1/2) \quad (2.301)$$

and the wave functions

$$\psi_n(x) = N_n \lambda_\omega^{-1/2} e^{-x^2/2\lambda_\omega^2} H_n(x/\lambda_\omega). \quad (2.302)$$

Here, λ_ω is the natural length scale of the oscillator

$$\lambda_\omega \equiv \sqrt{\frac{\hbar}{M\omega}}, \quad (2.303)$$

and N_n the normalization constant

$$N_n = (1/2^n n! \sqrt{\pi})^{1/2}. \quad (2.304)$$

It is easy to check that the wave functions satisfy the orthonormality relation

$$\int_{-\infty}^{\infty} dx \psi_n(x) \psi_{n'}(x)^* = \delta_{nn'}, \quad (2.305)$$

using the well-known orthogonality relation of Hermite polynomials¹⁵

$$\frac{1}{2^n n! \sqrt{\pi}} \int_{-\infty}^{\infty} dx e^{-x^2} H_n(x) H_{n'}(x) = \delta_{n,n'}. \quad (2.306)$$

2.7 General Time-Dependent Harmonic Action

A simple generalization of the harmonic oscillator with time-dependent frequency allows also for a time-dependent mass, so that the action (2.307) becomes

$$\mathcal{A}[x] = \int_{t_a}^{t_b} dt \frac{M}{2} [g(t)\dot{x}^2(t) - \Omega^2(t)x^2(t)], \quad (2.307)$$

with some dimensionless time-dependent factor $g(t)$. This factor changes the measure of path integration so that the time evolution amplitude can no longer be calculated from (2.260). To find the correct measure we must return to the canonical path integral (2.29) which now reads

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{i\mathcal{A}[p,x]/\hbar}, \quad (2.308)$$

with the canonical action

$$\mathcal{A}[p, x] = \int_{t_a}^{t_b} dt \left[p\dot{x} - \frac{p^2}{2Mg(t)} - \frac{M}{2}\Omega^2(t)x^2(t) \right]. \quad (2.309)$$

Integrating the momentum variables out in the sliced form of this path integral as in Eqs. (2.51)–(2.53) yields

$$(x_b t_b | x_a t_a) \approx \frac{1}{\sqrt{2\pi\hbar i\epsilon/Mg(t_{N+1})}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar i\epsilon/Mg(t_n)}} \right] \exp\left(\frac{i}{\hbar}\mathcal{A}^N\right). \quad (2.310)$$

The continuum limit of this path integral is written as

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x \sqrt{g} \exp\left\{\frac{i}{\hbar}\mathcal{A}[x]\right\}, \quad (2.311)$$

with the action (2.307).

The classical orbits solve the equation of motion

$$[-\partial_t g(t)\partial_t - \Omega^2(t)]x(t) = 0, \quad (2.312)$$

which, by the transformation

$$\tilde{x}(t) = \sqrt{g(t)}x(t), \quad \tilde{\Omega}^2(t) = \frac{1}{g(t)} \left[\Omega^2(t) + \frac{\dot{g}^2(t)}{4g(t)} - \frac{\ddot{g}(t)}{2} \right], \quad (2.313)$$

can be reduced to the previous form

$$\sqrt{g(t)} \left[-\partial_t^2 - \tilde{\Omega}^2(t) \right] \tilde{x}(t) = 0. \quad (2.314)$$

The result of the path integration is therefore

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x \sqrt{g} e^{i\mathcal{A}[x]/\hbar} = F(x_b, t_b; x_a, t_a) e^{i\mathcal{A}_{cl}/\hbar}, \quad (2.315)$$

with a fluctuation factor [compare (2.263)]

$$F(x_b, t_b; x_a, t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \frac{1}{\sqrt{D_a(t_b)}}, \quad (2.316)$$

where $D_a(t_b)$ is found from a generalization of the formulas (2.264)–(2.269). The classical action is

$$\mathcal{A}_{cl} = \frac{M}{2}(g_b x_b \dot{x}_b - g_a x_a \dot{x}_a), \quad (2.317)$$

where $g_b \equiv g(t_b)$, $g_a \equiv g(t_a)$. The solutions of the equation of motion can be expressed in terms of modified Gelfand-Yaglom functions (2.228) and (2.229) with the properties

$$[\partial_t g(t) \partial_t + \Omega^2(t)] D_a(t) = 0 ; \quad D_a(t_a) = 0, \quad \dot{D}_a(t_a) = 1/g_a, \quad (2.318)$$

$$[\partial_t g(t) \partial_t + \Omega^2(t)] D_b(t) = 0 ; \quad D_b(t_b) = 0, \quad \dot{D}_b(t_b) = -1/g_b, \quad (2.319)$$

as in (2.248):

$$x(x_b, x_a; t) = \frac{D_b(t)}{D_b(t_a)} x_a + \frac{D_a(t)}{D_a(t_b)} x_b. \quad (2.320)$$

This allows us to write the classical action (2.317) in the form

$$\mathcal{A}_{\text{cl}} = \frac{M}{2D_a(t_b)} \left[g_b x_b^2 \dot{D}_a(t_b) - g_a x_a^2 \dot{D}_b(t_a) - 2x_b x_a \right]. \quad (2.321)$$

From this we find, as in (2.269),

$$D_{\text{ren}} = D_a(t_b) = D_b(t_a) = -M \left(\frac{\partial^2 \mathcal{A}_{\text{cl}}}{\partial x_b \partial x_a} \right)^{-1}, \quad (2.322)$$

so that the fluctuation factor becomes

$$F(x_b, t_b; x_a, t_a) = \frac{1}{\sqrt{2\pi i \hbar}} \sqrt{-\frac{\partial^2 \mathcal{A}_{\text{cl}}}{\partial x_b \partial x_a}}. \quad (2.323)$$

As an example take a free particle with a time-dependent mass term, where

$$D_a(t) = \int_{t_a}^t dt' g^{-1}(t'), \quad D_b(t) = \int_t^{t_b} dt' g^{-1}(t'), \quad D_{\text{ren}} = D_a(t_b) = D_b(t_a) = \int_{t_a}^{t_b} dt' g^{-1}(t'), \quad (2.324)$$

and the classical action reads

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} \frac{(x_b - x_a)^2}{D_a(t_b)}. \quad (2.325)$$

The result can easily be generalized to an arbitrary harmonic action

$$\mathcal{A} = \int_{t_a}^{t_b} dt \frac{M}{2} [g(t) \dot{x}^2 + 2b(t) x \dot{x} - \Omega^2(t) x^2], \quad (2.326)$$

which is extremized by the Euler-Lagrange equation [recall (1.8)]

$$\left[\partial_t g(t) \partial_t + \dot{b}(t) + \Omega^2(t) \right] x = 0. \quad (2.327)$$

The solution of the path integral (2.315) is again given by (2.315), with the fluctuation factor (2.323), where \mathcal{A}_{cl} is the action (2.326) along the classical path connecting the endpoints.

A further generalization to D dimensions is obvious by adapting the procedure in Subsection 2.4.6, which makes Eqs. (2.318)–(2.320). matrix equations.

2.8 Path Integrals and Quantum Statistics

The path integral approach is useful to also understand the thermal equilibrium properties of a system. We assume the system to have a *time-independent* Hamiltonian and to be in contact with a reservoir of temperature T . As explained in Section 1.7, the bulk thermodynamic quantities can be determined from the quantum-statistical partition function

$$Z = \text{Tr} \left(e^{-\hat{H}/k_B T} \right) = \sum_n e^{-E_n/k_B T}. \quad (2.328)$$

This, in turn, may be viewed as an analytic continuation of the quantum-mechanical partition function

$$Z_{\text{QM}} = \text{Tr} \left(e^{-i(t_b-t_a)\hat{H}/\hbar} \right) \quad (2.329)$$

to the imaginary time

$$t_b - t_a = -\frac{i\hbar}{k_B T} \equiv -i\hbar\beta. \quad (2.330)$$

In the local particle basis $|x\rangle$, the quantum-mechanical trace corresponds to an integral over all positions so that the quantum-statistical partition function can be obtained by integrating the time evolution amplitude over $x_b = x_a$ and evaluating it at the analytically continued time:

$$Z \equiv \int_{-\infty}^{\infty} dx z(x) = \int_{-\infty}^{\infty} dx \langle x | e^{-\beta\hat{H}} | x \rangle = \int_{-\infty}^{\infty} dx (x t_b | x t_a) |_{t_b-t_a=-i\hbar\beta}. \quad (2.331)$$

The diagonal elements

$$z(x) \equiv \langle x | e^{-\beta\hat{H}} | x \rangle = (x t_b | x t_a) |_{t_b-t_a=-i\hbar\beta} \quad (2.332)$$

play the role of a *partition function density*. For a harmonic oscillator, this quantity has the explicit form [recall (2.175)]

$$z_\omega(x) = \frac{1}{\sqrt{2\pi\hbar/M}} \sqrt{\frac{\omega}{\sinh \hbar\beta\omega}} \exp \left(-\frac{M\omega}{\hbar} \tanh \frac{\hbar\beta\omega}{2} x^2 \right). \quad (2.333)$$

By splitting the Boltzmann factor $e^{-\beta\hat{H}}$ into a product of $N+1$ factors $e^{-\epsilon\hat{H}/\hbar}$ with $\epsilon = \hbar/k_B T(N+1)$, we can derive for Z a similar path integral representation just as for the corresponding quantum-mechanical partition function in (2.42), (2.48):

$$Z \equiv \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} dx_n \right] \quad (2.334)$$

$$\times \langle x_{N+1} | e^{-\epsilon\hat{H}/\hbar} | x_N \rangle \langle x_N | e^{-\epsilon\hat{H}/\hbar} | x_{N-1} \rangle \times \dots \times \langle x_2 | e^{-\epsilon\hat{H}/\hbar} | x_1 \rangle \langle x_1 | e^{-\epsilon\hat{H}/\hbar} | x_{N+1} \rangle.$$

As in the quantum-mechanical case, the matrix elements $\langle x_n | e^{-\epsilon\hat{H}/\hbar} | x_{n-1} \rangle$ are re-expressed in the form

$$\langle x_n | e^{-\epsilon\hat{H}/\hbar} | x_{n-1} \rangle \approx \int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} e^{ip_n(x_n-x_{n-1})/\hbar - \epsilon H(p_n, x_n)/\hbar}, \quad (2.335)$$

with the only difference that there is now no imaginary factor i in front of the Hamiltonian. The product (2.334) can thus be written as

$$Z \approx \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} dx_n \int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \exp \left(-\frac{1}{\hbar} \mathcal{A}_\epsilon^N \right), \quad (2.336)$$

where \mathcal{A}_e^N denotes the sum

$$\mathcal{A}_e^N = \sum_{n=1}^{N+1} [-ip_n(x_n - x_{n-1}) + \epsilon H(p_n, x_n)]. \quad (2.337)$$

In the continuum limit $\epsilon \rightarrow 0$, the sum goes over into the integral

$$\mathcal{A}_e[p, x] = \int_0^{\hbar\beta} d\tau [-ip(\tau)\dot{x}(\tau) + H(p(\tau), x(\tau))], \quad (2.338)$$

and the partition function is given by the path integral

$$Z = \int \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{-\mathcal{A}_e[p, x]/\hbar}. \quad (2.339)$$

In this expression, $p(\tau), x(\tau)$ may be considered as paths running along an “imaginary time axis” $\tau = it$. The expression $\mathcal{A}_e[p, x]$ is very similar to the mechanical canonical action (2.27). Since it governs the quantum-statistical path integrals it is called *quantum-statistical action* or *Euclidean action*, indicated by the subscript e . The name alludes to the fact that a D -dimensional Euclidean space extended by an imaginary-time axis $\tau = it$ has the same geometric properties as a $D + 1$ -dimensional Euclidean space. For instance, a four-vector in a Minkowski spacetime has a square length $dx^2 = -(cdt)^2 + (d\mathbf{x})^2$. Continued to an imaginary time, this becomes $dx^2 = (cd\tau)^2 + (d\mathbf{x})^2$ which is the square distance in a Euclidean four-dimensional space with four-vectors $(c\tau, \mathbf{x})$.

The integrand of the Euclidean action (2.339) is the *Euclidean Lagrangian* L_e . It is related to the Hamiltonian by the *Euclidean Legendre transform* [compare (1.9)]

$$H = L_e + i \frac{\partial L_e}{\partial \dot{x}} \dot{x} = L_e + ip\dot{x} \quad (2.340)$$

in which \dot{x} is eliminated in favor of $p = \partial L_e / \partial \dot{x}$ [compare (1.10)].

Just as in the path integral for the quantum-mechanical partition function (2.48), the measure of integration $\oint \mathcal{D}x \int \mathcal{D}p / 2\pi\hbar$ in the quantum-statistical expression (2.339) is automatically symmetric in all p 's and x 's:

$$\oint \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} = \oint \frac{\mathcal{D}p}{2\pi\hbar} \int \mathcal{D}x = \prod_{n=1}^{N+1} \int_{-\infty}^{\infty} dx_n \int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar}. \quad (2.341)$$

The symmetry is of course due to the trace integration over all initial \equiv final positions.

Most remarks made in connection with Eq. (2.48) carry over to the present case. The above path integral (2.339) is a natural extension of the rules of classical statistical mechanics. According to these, each cell in phase space $dx dp / h$ is occupied with equal statistical weight, with the probability factor $e^{-E/k_B T}$. In quantum statistics, the *paths* of all particles fluctuate evenly over the cells in *path phase space* $\prod_n dx(\tau_n) dp(\tau_n) / h$ ($\tau_n \equiv n\epsilon$), each path carrying a probability factor $e^{-\mathcal{A}_e/\hbar}$ involving the Euclidean action of the system.

2.9 Density Matrix

The partition function does not determine any local thermodynamic quantities. Important local information resides in the thermal analog of the time evolution amplitude $\langle x_b | e^{-\hat{H}/k_B T} | x_a \rangle$. Consider, for instance, the diagonal elements of this amplitude renormalized by a factor Z^{-1} :

$$\rho(x_a) \equiv Z^{-1} \langle x_a | e^{-\hat{H}/k_B T} | x_a \rangle. \quad (2.342)$$

They determine the thermal average of the particle density of a quantum-statistical system. Due to (2.334), the factor Z^{-1} makes the spatial integral over ρ equal to unity:

$$\int_{-\infty}^{\infty} dx \rho(x) = 1. \quad (2.343)$$

By inserting into (2.342) a complete set of eigenfunctions $\psi_n(x)$ of the Hamiltonian operator \hat{H} , we find the spectral decomposition

$$\rho(x_a) = \sum_n |\psi_n(x_a)|^2 e^{-\beta E_n} / \sum_n e^{-\beta E_n}. \quad (2.344)$$

Since $|\psi_n(x_a)|^2$ is the probability distribution of the system in the eigenstate $|n\rangle$, while the ratio $e^{-\beta E_n} / \sum_n e^{-\beta E_n}$ is the normalized probability to encounter the system in the state $|n\rangle$, the quantity $\rho(x_a)$ represents the normalized average particle density in space as a function of temperature.

Note the limiting properties of $\rho(x_a)$. In the limit $T \rightarrow 0$, only the lowest energy state survives and $\rho(x_a)$ tends towards the particle distribution in the ground state

$$\rho(x_a) \xrightarrow{T \rightarrow 0} |\psi_0(x_a)|^2. \quad (2.345)$$

In the opposite limit of high temperatures, quantum effects are expected to become irrelevant and the partition function should converge to the classical expression (1.538) which is the integral over the phase space of the Boltzmann distribution

$$Z \xrightarrow{T \rightarrow \infty} Z_{\text{cl}} = \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} e^{-H(p,x)/k_B T}. \quad (2.346)$$

We therefore expect the large- T limit of $\rho(x)$ to be equal to the *classical particle distribution*

$$\rho(x) \xrightarrow{T \rightarrow \infty} \rho_{\text{cl}}(x) = Z_{\text{cl}}^{-1} \int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} e^{-H(p,x)/k_B T}. \quad (2.347)$$

Within the path integral approach, this limit will be discussed in more detail in Section 2.13. At this place we roughly argue as follows: When going in the original time-sliced path integral (2.334) to large T , i.e., small $\tau_b - \tau_a = \hbar/k_B T$, we may keep only a single time slice and write

$$Z \approx \left[\int_{-\infty}^{\infty} dx \right] \langle x | e^{-\epsilon \hat{H}/\hbar} | x \rangle, \quad (2.348)$$

with

$$\langle x|e^{-\epsilon\hat{H}}|x\rangle \approx \int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} e^{-\epsilon H(p_n, x)/\hbar}. \quad (2.349)$$

After substituting $\epsilon = \tau_b - \tau_a$ this gives directly (2.347). Physically speaking, the path has at high temperatures “no (imaginary) time” to fluctuate, and only one term in the product of integrals needs to be considered.

If $H(p, x)$ has the standard form

$$H(p, x) = \frac{p^2}{2M} + V(x), \quad (2.350)$$

the momentum integral is Gaussian in p and can be done using the formula

$$\int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} e^{-ap^2/2\hbar} = \frac{1}{\sqrt{2\pi\hbar a}}. \quad (2.351)$$

This leads to the pure x -integral for the classical partition function

$$Z_{\text{cl}} = \int_{-\infty}^{\infty} \frac{dx}{\sqrt{2\pi\hbar^2/Mk_B T}} e^{-V(x)/k_B T} = \int_{-\infty}^{\infty} \frac{dx}{l_e(\hbar\beta)} e^{-\beta V(x)}. \quad (2.352)$$

In the second expression we have introduced the length

$$l_e(\hbar\beta) \equiv \sqrt{2\pi\hbar^2\beta/M}. \quad (2.353)$$

It is the thermal (or Euclidean) analog of the characteristic length $l(t_b - t_a)$ introduced before in (2.131). It is called the *de Broglie wavelength associated with the temperature* $T = 1/k_B\beta$ or, in short, the *thermal de Broglie wavelength*.

Omitting the x -integration in (2.352) renders the large- T limit $\rho(x)$, the classical particle distribution

$$\rho(x) \xrightarrow{T \rightarrow \infty} \rho_{\text{cl}}(x) = Z_{\text{cl}}^{-1} \frac{1}{l_e(\hbar\beta)} e^{-\bar{V}(x)}. \quad (2.354)$$

For a free particle, the integral over x in (2.352) diverges. If we imagine the length of the x -axis to be very large but finite, say equal to L , the partition function is equal to

$$Z_{\text{cl}} = \frac{L}{l_e(\hbar\beta)}. \quad (2.355)$$

In D dimensions, this becomes

$$Z_{\text{cl}} = \frac{V_D}{l_e^D(\hbar\beta)}, \quad (2.356)$$

where V_D is the volume of the D -dimensional system. For a harmonic oscillator with potential $M\omega^2 x^2/2$, the integral over x in (2.352) is finite and yields, in the D -dimensional generalization

$$Z_{\text{cl}} = \frac{l_\omega^D}{l_e^D(\hbar\beta)}, \quad (2.357)$$

where

$$l_\omega \equiv \sqrt{\frac{2\pi}{\beta M \omega^2}} \quad (2.358)$$

denotes the classical length scale defined by the frequency of the harmonic oscillator. It is related to the quantum-mechanical one λ_ω of Eq. (2.303) by

$$l_\omega l_e(\hbar\beta) = 2\pi \lambda_\omega^2. \quad (2.359)$$

Thus we obtain the *mnemonic rule* for going over from the partition function of a harmonic oscillator to that of a free particle: we must simply replace

$$l_\omega \xrightarrow{\omega \rightarrow 0} L, \quad (2.360)$$

or

$$\frac{1}{\omega} \xrightarrow{\omega \rightarrow 0} \sqrt{\frac{\beta M}{2\pi}} L. \quad (2.361)$$

The real-time version of this is, of course,

$$\frac{1}{\omega} \xrightarrow{\omega \rightarrow 0} \sqrt{\frac{(t_b - t_a)M}{2\pi\hbar}} L. \quad (2.362)$$

Let us write down a path integral representation for $\rho(x)$. Omitting in (2.339) the final trace integration over $x_b \equiv x_a$ and normalizing the expression by a factor Z^{-1} , we obtain

$$\begin{aligned} \rho(x_a) &= Z^{-1} \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{-\mathcal{A}_e[p,x]/\hbar} \\ &= Z^{-1} \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} \mathcal{D}x e^{-\mathcal{A}_e[x]/\hbar}. \end{aligned} \quad (2.363)$$

The thermal equilibrium expectation of an arbitrary Hermitian operator \hat{O} is given by

$$\langle \hat{O} \rangle_T \equiv Z^{-1} \sum_n e^{-\beta E_n} \langle n | \hat{O} | n \rangle. \quad (2.364)$$

In the local basis $|x\rangle$, this becomes

$$\langle \hat{O} \rangle_T = Z^{-1} \iint_{-\infty}^{\infty} dx_b dx_a \langle x_b | e^{-\beta \hat{H}} | x_a \rangle \langle x_a | \hat{O} | x_b \rangle. \quad (2.365)$$

An arbitrary function of the position operator \hat{x} has the expectation

$$\langle f(\hat{x}) \rangle_T = Z^{-1} \iint_{-\infty}^{\infty} dx_b dx_a \langle x_b | e^{-\beta \hat{H}} | x_a \rangle \delta(x_b - x_a) f(x_a) = \int dx \rho(x) f(x). \quad (2.366)$$

The particle density $\rho(x_a)$ determines the thermal averages of local observables.

If f depends also on the momentum operator \hat{p} , then the off-diagonal matrix elements $\langle x_b | e^{-\beta \hat{H}} | x_a \rangle$ are also needed. They are contained in the *density matrix*

introduced for pure quantum systems in Eq. (1.221), and reads now in a thermal ensemble of temperature T :

$$\rho(x_b, x_a) \equiv Z^{-1} \langle x_b | e^{-\beta \hat{H}} | x_a \rangle, \quad (2.367)$$

whose diagonal values coincide with the above particle density $\rho(x_a)$.

It is useful to keep the analogy between quantum mechanics and quantum statistics as close as possible and to introduce the time translation operator along the imaginary time axis

$$\hat{U}_e(\tau_b, \tau_a) \equiv e^{-(\tau_b - \tau_a) \hat{H} / \hbar}, \quad \tau_b > \tau_a, \quad (2.368)$$

defining its local matrix elements as *imaginary* or *Euclidean* time evolution amplitudes¹⁶

$$(x_b \tau_b | x_a \tau_a) \equiv \langle x_b | \hat{U}_e(\tau_b, \tau_a) | x_a \rangle, \quad \tau_b > \tau_a. \quad (2.369)$$

As in the real-time case, we shall only consider the causal time-ordering $\tau_b > \tau_a$. Otherwise the partition function and the density matrix do not exist in systems with energies up to infinity. Given the imaginary-time amplitudes, the partition function is found by integrating over the diagonal elements

$$Z = \int_{-\infty}^{\infty} dx (x \hbar \beta | x 0), \quad (2.370)$$

and the density matrix

$$\rho(x_b, x_a) = Z^{-1} (x_b \hbar \beta | x_a 0). \quad (2.371)$$

For the sake of generality we may sometimes also consider the imaginary-time evolution operators for time-dependent Hamiltonians and the associated amplitudes. They are obtained by time-slicing the local matrix elements of the operator

$$\hat{U}(\tau_b, \tau_a) = T_\tau \exp \left[-\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \hat{H}(-i\tau) \right]. \quad (2.372)$$

Here T_τ is an ordering operator along the imaginary-time axis.

It must be emphasized that the usefulness of the operator (2.372) in describing thermodynamic phenomena is restricted to the Hamiltonian operator $\hat{H}(t)$ depending very weakly on the physical time t . The system has to remain close to equilibrium at all times. This is the range of validity of the so-called *linear response theory* (see Chapter 18 for more details).

The imaginary-time evolution amplitude (2.369) has a path integral representation which is obtained by dropping the final integration in (2.336) and relaxing the condition $x_b = x_a$:

$$(x_b \tau_b | x_a \tau_a) \approx \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \exp \left(-\mathcal{A}_e^N / \hbar \right). \quad (2.373)$$

¹⁶The imaginary-time amplitude $(x_b \beta | x_a 0) = \langle x_b | e^{-\beta \hat{H}} | x_a \rangle$ is often referred to as *heat kernel*.

The time-sliced Euclidean action is

$$\mathcal{A}_e^N = \sum_{n=1}^{N+1} [-ip_n(x_n - x_{n-1}) + \epsilon H(p_n, x_n, \tau_n)] \quad (2.374)$$

(we have omitted the factor $-i$ in the τ -argument of H). In the continuum limit this is written as a path integral

$$(x_b\tau_b|x_a\tau_a) = \int \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_e[p, x] \right\} \quad (2.375)$$

[by analogy with (2.339)]. For a Hamiltonian of the standard form (2.7),

$$H(p, x, \tau) = \frac{p^2}{2M} + V(x, \tau),$$

with a smooth potential $V(x, \tau)$, the momenta can be integrated out, just as in (2.53), and the Euclidean version of the pure x -space path integral (2.54) leads to (2.55):

$$\begin{aligned} (x_b\tau_b|x_a\tau_a) &= \int \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\partial_\tau x)^2 + V(x, \tau) \right] \right\} \\ &\approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\beta/M}} \right] \\ &\quad \times \exp \left\{ -\frac{1}{\hbar} \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2} \left(\frac{x_n - x_{n-1}}{\epsilon} \right)^2 + V(x_n, \tau_n) \right] \right\}. \end{aligned} \quad (2.376)$$

From this we calculate the quantum-statistical partition function

$$\begin{aligned} Z &= \int_{-\infty}^{\infty} dx (x|\hbar\beta|x0) \\ &= \int dx \int_{x(0)=x}^{x(\hbar\beta)=x} \mathcal{D}x e^{-\mathcal{A}_e[x]/\hbar} = \oint \mathcal{D}x e^{-\mathcal{A}_e[x]/\hbar}, \end{aligned} \quad (2.377)$$

where $\mathcal{A}_e[x]$ is the Euclidean version of the Lagrangian action

$$\mathcal{A}_e[x] = \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} x'^2 + V(x, \tau) \right]. \quad (2.378)$$

The prime denotes differentiation with respect to the imaginary time. As in the quantum-mechanical partition function in (2.63), the path integral $\oint \mathcal{D}x$ now stands for

$$\oint \mathcal{D}x \approx \prod_{n=1}^{N+1} \int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar\epsilon/M}}. \quad (2.379)$$

It contains no extra $1/\sqrt{2\pi\hbar\epsilon/M}$ factor, as in (2.376), due to the trace integration over the exterior x .

The condition $x(\hbar\beta) = x(0)$ is most easily enforced by expanding $x(\tau)$ into a Fourier series

$$x(\tau) = \sum_{m=-\infty}^{\infty} \frac{1}{\sqrt{N+1}} e^{-i\omega_m \tau} x_m, \quad (2.380)$$

with the Matsubara frequencies

$$\omega_m \equiv 2\pi m k_B T / \hbar = \frac{2\pi m}{\hbar\beta}, \quad m = 0, \pm 1, \pm 2, \dots \quad (2.381)$$

When considered as functions on the entire τ -axis, the paths are periodic in $\hbar\beta$ at any τ , i.e.,

$$x(\tau) = x(\tau + \hbar\beta). \quad (2.382)$$

Thus the path integral for the quantum-statistical partition function comprises all periodic paths with a period $\hbar\beta$. In the time-sliced path integral (2.376), the coordinates $x(\tau)$ are needed only at the discrete times $\tau_n = n\epsilon$. Correspondingly, the sum over m in (2.380) can be restricted to run from $m = -N/2$ to $N/2$ for even N and from $-(N-1)/2$ to $(N+1)/2$ for odd N (see Fig. 2.3). In order to have a real $x(\tau_n)$, we must require that

$$x_m = x_{-m}^* \quad (\text{modulo } N+1). \quad (2.383)$$

Note that the Matsubara frequencies in the expansion of the paths $x(\tau)$ are now twice as big as the frequencies ν_m in the quantum fluctuations (2.115) (after analytic continuation of $t_b - t_a$ to $-i\hbar/k_B T$). Still, they have about the same total number, since they run over positive *and* negative integers. An exception is the zero frequency $\omega_m = 0$, which is *included* here, in contrast to the frequencies ν_m in (2.115) which run only over positive $m = 1, 2, 3, \dots$. This is necessary to describe paths with arbitrary nonzero endpoints $x_b = x_a = x$ (included in the trace).

2.10 Quantum Statistics of the Harmonic Oscillator

The harmonic oscillator is a good example for solving the quantum-statistical path integral. The τ -axis is sliced at $\tau_n = n\epsilon$, with $\epsilon \equiv \hbar\beta/(N+1)$ ($n = 0, \dots, N+1$), and the partition function is given by the $N \rightarrow \infty$ -limit of the product of integrals

$$Z_\omega^N = \prod_{n=0}^N \left[\int_{-\infty}^{\infty} \frac{dx_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \exp(-\mathcal{A}_e^N/\hbar), \quad (2.384)$$

where \mathcal{A}_e^N is the time-sliced Euclidean oscillator action

$$\mathcal{A}_e^N = \frac{M}{2\epsilon} \sum_{n=1}^{N+1} x_n (-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2) x_n. \quad (2.385)$$

Integrating out the x_n 's, we find immediately

$$Z_\omega^N = \frac{1}{\sqrt{\det_{N+1}(-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2)}}. \quad (2.386)$$

Figure 2.3 Illustration of the eigenvalues (2.387) of the fluctuation matrix in the action (2.385) for even and odd N .

Let us evaluate the fluctuation determinant via the product of eigenvalues which diagonalize the matrix $-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2$ in the sliced action (2.385). They are

$$\epsilon^2 \Omega_m \bar{\Omega}_m + \epsilon^2 \omega^2 = 2 - 2 \cos \omega_m \epsilon + \epsilon^2 \omega^2, \quad (2.387)$$

with the Matsubara frequencies ω_m . For $\omega = 0$, the eigenvalues are pictured in Fig. 2.3. The action (2.385) becomes diagonal after going to the Fourier components x_m . To do this we arrange the real and imaginary parts $\text{Re } x_m$ and $\text{Im } x_m$ in a row vector

$$(\text{Re } x_1, \text{Im } x_1; \text{Re } x_2, \text{Im } x_2; \dots; \text{Re } x_n, \text{Im } x_n; \dots),$$

and see that it is related to the time-sliced positions $x_n = x(\tau_n)$ by a transformation matrix with the rows

$$\begin{aligned} T_{mn} x_n &= (T_m)_n x_n \\ &= \sqrt{\frac{2}{N+1}} \left(\frac{1}{\sqrt{2}}, \cos \frac{m}{N+1} 2\pi \cdot 1, \sin \frac{m}{N+1} 2\pi \cdot 1, \right. \\ &\quad \left. \cos \frac{m}{N+1} 2\pi \cdot 2, \sin \frac{m}{N+1} 2\pi \cdot 2, \dots \right. \\ &\quad \left. \dots, \cos \frac{m}{N+1} 2\pi \cdot n, \sin \frac{m}{N+1} 2\pi \cdot n, \dots \right)_n x_n. \end{aligned} \quad (2.388)$$

For each row index $m = 0, \dots, N$, the column index n runs from zero to $N/2$ for even N , and to $(N+1)/2$ for odd N . In the odd case, the last column $\sin \frac{m}{N+1} 2\pi \cdot n$ with $n = (N+1)/2$ vanishes identically and must be dropped, so that the number of columns in T_{mn} is in both cases $N+1$, as it should be. For odd N , the second-last column of T_{mn} is an alternating sequence ± 1 . Thus, for a proper normalization, it has to be multiplied by an extra normalization factor $1/\sqrt{2}$, just as the elements in the first column. An argument similar to (2.120), (2.121) shows that the resulting matrix is orthogonal. Thus, we can diagonalize the sliced action in (2.385) as follows

$$\mathcal{A}_e^N = \frac{M}{2} \epsilon \begin{cases} \left[\omega^2 x_0^2 + 2 \sum_{m=1}^{N/2} (\Omega_m \bar{\Omega}_m + \omega^2) |x_m|^2 \right] & \text{for } N = \text{even,} \\ \left[\omega^2 x_0^2 + (\Omega_{(N+1)/2} \bar{\Omega}_{(N+1)/2} + \omega^2) x_{N+1}^2 \right. \\ \quad \left. + 2 \sum_{m=1}^{(N-1)/2} (\Omega_m \bar{\Omega}_m + \omega^2) |x_m|^2 \right] & \text{for } N = \text{odd.} \end{cases} \quad (2.389)$$

Thanks to the orthogonality of T_{mn} , the measure $\prod_n \int_{-\infty}^{\infty} dx(\tau_n)$ transforms simply into

$$\int_{-\infty}^{\infty} dx_0 \prod_{m=1}^{N/2} \int_{-\infty}^{\infty} d \text{Re } x_m \int_{-\infty}^{\infty} d \text{Im } x_m \quad \text{for } N = \text{even,}$$

(2.390)

$$\int_{-\infty}^{\infty} dx_0 \int_{-\infty}^{\infty} dx_{(N+1)/2} \prod_{m=1}^{(N-1)/2} \int_{-\infty}^{\infty} d\operatorname{Re} x_m \int_{-\infty}^{\infty} d\operatorname{Im} x_m \quad \text{for } N = \text{odd.}$$

By performing the Gaussian integrals we obtain the partition function

$$\begin{aligned} Z_{\omega}^N &= [\det_{N+1}(-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2)]^{-1/2} = \left[\prod_{m=0}^N (\epsilon^2 \Omega_m \bar{\Omega}_m + \epsilon^2 \omega^2) \right]^{-1/2} \\ &= \left\{ \prod_{m=0}^N [2(1 - \cos \omega_m \epsilon) + \epsilon^2 \omega^2] \right\}^{-1/2} = \left[\prod_{m=0}^N \left(4 \sin^2 \frac{\omega_m \epsilon}{2} + \epsilon^2 \omega^2 \right) \right]^{-1/2}. \end{aligned} \quad (2.391)$$

Thanks to the periodicity of the eigenvalues under the replacement $n \rightarrow n + N + 1$, the result has become a unique product expression for both even and odd N .

It is important to realize that contrary to the fluctuation factor (2.162) in the real-time amplitude, the partition function (2.391) contains the square root of only positive eigenmodes as a unique result of Gaussian integrations. There are no phase subtleties as in the Fresnel integral (1.337).

To calculate the product, we observe that upon decomposing

$$\sin^2 \frac{\omega_m \epsilon}{2} = \left(1 + \cos \frac{\omega_m \epsilon}{2} \right) \left(1 - \cos \frac{\omega_m \epsilon}{2} \right), \quad (2.392)$$

the sequence of first factors

$$1 + \cos \frac{\omega_m \epsilon}{2} \equiv 1 + \cos \frac{\pi m}{N+1} \quad (2.393)$$

runs for $m = 1, \dots, N$ through the same values as the sequence of second factors

$$1 - \cos \frac{\omega_m \epsilon}{2} = 1 - \cos \frac{\pi m}{N+1} \equiv 1 + \cos \pi \frac{N+1-m}{N+1}, \quad (2.394)$$

except in an opposite order. Thus, separating out the $m = 0$ -term, we rewrite (2.391) in the form

$$Z_{\omega}^N = \frac{1}{\epsilon \omega} \left[\prod_{m=1}^N 2 \left(1 - \cos \frac{\omega_m \epsilon}{2} \right) \right]^{-1} \left[\prod_{m=1}^N \left(1 + \frac{\epsilon^2 \omega^2}{4 \sin^2 \frac{\omega_m \epsilon}{2}} \right) \right]^{-1/2}. \quad (2.395)$$

The first factor on the right-hand side is the quantum-mechanical fluctuation determinant of the free-particle determinant $\det_N(-\epsilon^2 \nabla \bar{\nabla}) = N + 1$ [see (2.128)], so that we obtain for both even and odd N

$$Z_{\omega}^N = \frac{k_B T}{\hbar \omega} \left[\prod_{m=1}^N \left(1 + \frac{\epsilon^2 \omega^2}{4 \sin^2 \frac{\omega_m \epsilon}{2}} \right) \right]^{-1/2}. \quad (2.396)$$

To evaluate the remaining product, we must distinguish again between even and odd cases of N . For even N , where every eigenvalue occurs twice (see Fig. 2.3), we obtain

$$Z_{\omega}^N = \frac{k_B T}{\hbar \omega} \left[\prod_{m=1}^{N/2} \left(1 + \frac{\epsilon^2 \omega^2}{4 \sin^2 \frac{m\pi}{N+1}} \right) \right]^{-1}. \quad (2.397)$$

For odd N , the term with $m = (N + 1)/2$ occurs only once and must be treated separately so that

$$Z_{\omega}^N = \frac{k_B T}{\hbar \omega} \left[\left(1 + \frac{\epsilon^2 \omega^2}{4} \right)^{1/2} \prod_{m=1}^{(N-1)/2} \left(1 + \frac{\epsilon^2 \omega^2}{4 \sin^2 \frac{m\pi}{N+1}} \right) \right]^{-1}. \quad (2.398)$$

We now introduce the parameter $\tilde{\omega}_e$, the Euclidean analog of (2.163), via the equations

$$\sin i \frac{\tilde{\omega}_e \epsilon}{2} \equiv i \frac{\omega \epsilon}{2}, \quad \sinh \frac{\tilde{\omega}_e \epsilon}{2} \equiv \frac{\omega \epsilon}{2}. \quad (2.399)$$

In the odd case, the product formula¹⁷

$$\prod_{m=1}^{(N-1)/2} \left[1 - \frac{\sin^2 x}{\sin^2 \frac{m\pi}{(N+1)}} \right] = \frac{2}{\sin 2x} \frac{\sin[(N+1)x]}{(N+1)} \quad (2.400)$$

[similar to (2.165)] yields, with $x = \tilde{\omega}_e \epsilon / 2$,

$$Z_\omega^N = \frac{k_B T}{\hbar \omega} \left[\frac{1}{\sinh(\tilde{\omega}_e \epsilon / 2)} \frac{\sinh[(N+1)\tilde{\omega}_e \epsilon / 2]}{N+1} \right]^{-1}. \quad (2.401)$$

In the even case, the formula¹⁸

$$\prod_{m=1}^{N/2} \left[1 - \frac{\sin^2 x}{\sin^2 \frac{m\pi}{(N+1)}} \right] = \frac{1}{\sin x} \frac{\sin[(N+1)x]}{(N+1)}, \quad (2.402)$$

produces once more the same result as in Eq. (2.401). Inserting Eq. (2.399) leads to the partition function on the sliced imaginary time axis:

$$Z_\omega^N = \frac{1}{2 \sinh(\hbar \tilde{\omega}_e \beta / 2)}. \quad (2.403)$$

The partition function can be expanded into the following series

$$Z_\omega^N = e^{-\hbar \tilde{\omega}_e / 2k_B T} + e^{-3\hbar \tilde{\omega}_e / 2k_B T} + e^{-5\hbar \tilde{\omega}_e / 2k_B T} + \dots \quad (2.404)$$

By comparison with the general spectral expansion (2.328), we display the energy eigenvalues of the system:

$$E_n = \left(n + \frac{1}{2} \right) \hbar \tilde{\omega}_e. \quad (2.405)$$

They show the typical linearly rising oscillator sequence with

$$\tilde{\omega}_e = \frac{2}{\epsilon} \operatorname{arsinh} \frac{\omega \epsilon}{2} \quad (2.406)$$

playing the role of the frequency on the sliced time axis, and $\hbar \tilde{\omega}_e / 2$ being the zero-point energy.

In the continuum limit $\epsilon \rightarrow 0$, the time-sliced partition function Z_ω^N goes over into the usual oscillator partition function

$$Z_\omega = \frac{1}{2 \sinh(\beta \hbar \omega / 2)}. \quad (2.407)$$

In D dimensions this becomes, of course, $[2 \sinh(\beta \hbar \omega / 2)]^{-D}$, due to the additivity of the action in each component of \mathbf{x} .

Note that the continuum limit of the product in (2.396) can also be taken factor by factor. Then Z_ω becomes

$$Z_\omega = \frac{k_B T}{\hbar \omega} \left[\prod_{m=1}^{\infty} \left(1 + \frac{\omega^2}{\omega_m^2} \right) \right]^{-1}. \quad (2.408)$$

¹⁷I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 1.391.1.

¹⁸*ibid.*, formula 1.391.3.

According to formula (2.173), the product $\prod_{m=1}^{\infty} \left(1 + \frac{x^2}{m^2\pi^2}\right)$ converges rapidly against $\sinh x/x$ and we find with $x = \hbar\omega\beta/2$

$$Z_{\omega} = \frac{k_B T}{\hbar\omega} \frac{\hbar\omega/2k_B T}{\sinh(\hbar\omega/2k_B T)} = \frac{1}{2 \sinh(\beta\hbar\omega/2)}. \quad (2.409)$$

As discussed after Eq. (2.183), the continuum limit can be taken in each factor since the product in (2.396) contains only ratios of frequencies.

Just as in the quantum-mechanical case, this procedure of obtaining the continuum limit can be summarized in the sequence of equations arriving at a ratio of differential operators

$$\begin{aligned} Z_{\omega}^N &= [\det_{N+1}(-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2)]^{-1/2} \\ &= [\det'_{N+1}(-\epsilon^2 \nabla \bar{\nabla})]^{-1/2} \left[\frac{\det_{N+1}(-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2)}{\det'_{N+1}(-\epsilon^2 \nabla \bar{\nabla})} \right]^{-1/2} \\ &\xrightarrow{\epsilon \rightarrow 0} \frac{k_B T}{\hbar} \left[\frac{\det(-\partial_{\tau}^2 + \omega^2)}{\det'(-\partial_{\tau}^2)} \right]^{-1/2} = \frac{k_B T}{\hbar\omega} \prod_{m=1}^{\infty} \left[\frac{\omega_m^2 + \omega^2}{\omega_m^2} \right]^{-1}. \end{aligned} \quad (2.410)$$

In the $\omega = 0$ -determinants, the zero Matsubara frequency is excluded to obtain a finite expression. This is indicated by a prime. The differential operator $-\partial_{\tau}^2$ acts on real functions which are periodic under the replacement $\tau \rightarrow \tau + \hbar\beta$. Remember that each eigenvalue ω_m^2 of $-\partial_{\tau}^2$ occurs twice, except for the zero frequency $\omega_0 = 0$, which appears only once.

Let us finally mention that the results of this section could also have been obtained directly from the quantum-mechanical amplitude (2.175) [or with the discrete times from (2.199)] by an analytic continuation of the time difference $t_b - t_a$ to imaginary values $-i(\tau_b - \tau_a)$:

$$\begin{aligned} (x_b \tau_b | x_a \tau_a) &= \frac{1}{\sqrt{2\pi\hbar/M}} \sqrt{\frac{\omega}{\sinh \omega(\tau_b - \tau_a)}} \\ &\times \exp \left\{ -\frac{1}{2\hbar} \frac{M\omega}{\sinh \omega(\tau_b - \tau_a)} [(x_b^2 + x_a^2) \cosh \omega(\tau_b - \tau_a) - 2x_b x_a] \right\}. \end{aligned} \quad (2.411)$$

By setting $x = x_b = x_a$ and integrating over x , we obtain [compare (2.333)]

$$\begin{aligned} Z_{\omega} &= \int_{-\infty}^{\infty} dx (x \tau_b | x \tau_a) = \frac{1}{\sqrt{2\pi\hbar(\tau_b - \tau_a)/M}} \sqrt{\frac{\omega(\tau_b - \tau_a)}{\sinh[\omega(\tau_b - \tau_a)]}} \\ &\times \frac{\sqrt{2\pi\hbar \sinh[\omega(\tau_b - \tau_a)]/\omega M}}{2 \sinh[\omega(\tau_b - \tau_a)/2]} = \frac{1}{2 \sinh[\omega(\tau_b - \tau_a)/2]}. \end{aligned} \quad (2.412)$$

Upon equating $\tau_b - \tau_a = \hbar\beta$, we retrieve the partition function (2.407). A similar treatment of the discrete-time version (2.199) would have led to (2.403). The main reason for presenting an independent direct evaluation in the space of real periodic functions was to display the frequency structure of periodic paths and to see the difference with respect to the quantum-mechanical paths with fixed ends. We also wanted to show how to handle the ensuing product expressions.

For applications in polymer physics (see Chapter 15) one also needs the partition function of all path fluctuations with open ends

$$\begin{aligned} Z_{\omega}^{\text{open}} &= \int_{-\infty}^{\infty} dx_b \int_{-\infty}^{\infty} dx_a (x_b \tau_b | x_a \tau_a) = \frac{1}{\sqrt{2\pi\hbar(\tau_b - \tau_a)/M}} \sqrt{\frac{\omega(\tau_b - \tau_a)}{\sinh[\omega(\tau_b - \tau_a)]}} \frac{2\pi\hbar}{M\omega} \\ &= \sqrt{\frac{2\pi\hbar}{M\omega}} \frac{1}{\sqrt{\sinh[\omega(\tau_b - \tau_a)]}}. \end{aligned} \quad (2.413)$$

The prefactor is $\sqrt{2\pi}$ times the length scale λ_{ω} of Eq. (2.303).

2.11 Time-Dependent Harmonic Potential

It is often necessary to calculate thermal fluctuation determinants for the case of a time-dependent frequency $\Omega(\tau)$ which is periodic under $\tau \rightarrow \tau + \hbar\beta$. As in Section 2.3.6, we consider the amplitude

$$\begin{aligned} (x_b\tau_b|x_a\tau_a) &= \int \mathcal{D}'x \int \frac{\mathcal{D}p}{2\pi\hbar} e^{-\int_{\tau_a}^{\tau_b} d\tau [-ip\dot{x} + p^2/2M + M\Omega^2(\tau)x^2/2]/\hbar} \\ &= \int \mathcal{D}x e^{-\int_{\tau_a}^{\tau_b} d\tau [M\dot{x}^2 + \Omega^2(\tau)x^2]/2\hbar}. \end{aligned} \quad (2.414)$$

The time-sliced fluctuation factor is [compare (2.202)]

$$F^N(\tau_a - \tau_b) = \det_{N+1}[-\epsilon^2\nabla\bar{\nabla} + \epsilon\Omega^2(\tau)]^{-1/2}, \quad (2.415)$$

with the continuum limit

$$F(\tau_a - \tau_b) = \frac{k_B T}{\hbar} \left[\frac{\det(-\partial_\tau^2 + \Omega^2(\tau))}{\det'(-\partial_\tau^2)} \right]^{-1/2}. \quad (2.416)$$

Actually, in the thermal case it is preferable to use the oscillator result for normalizing the fluctuation factor, rather than the free-particle result, and to work with the formula

$$F(\tau_b, \tau_a) = \frac{1}{2 \sinh(\beta\hbar\omega/2)} \left[\frac{\det(-\partial_\tau^2 + \Omega^2(\tau))}{\det(-\partial_\tau^2 + \omega^2)} \right]^{-1/2}. \quad (2.417)$$

This has the advantage that the determinant in the denominator contains no zero eigenvalue which would require a special treatment as in (2.410); the operator $-\partial_\tau^2 + \omega^2$ is positive.

As in the quantum-mechanical case, the spectrum of eigenvalues is not known for general $\Omega(\tau)$. It is, however, possible to find a differential equation for the entire determinant, analogous to the Gelfand-Yaglom formula (2.209), with the initial condition (2.214), although the derivation is now much more tedious. The origin of the additional difficulties lies in the periodic boundary condition which introduces additional nonvanishing elements -1 in the upper right and lower left corners of the matrix $-\epsilon^2\nabla\bar{\nabla}$ [compare (2.107)]:

$$-\epsilon^2\nabla\bar{\nabla} = \begin{pmatrix} 2 & -1 & 0 & \dots & 0 & 0 & -1 \\ -1 & 2 & -1 & \dots & 0 & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & & 0 & \dots & -1 & 2 & -1 \\ -1 & 0 & 0 & \dots & 0 & -1 & 2 \end{pmatrix}. \quad (2.418)$$

To better understand the relation with the previous result we shall replace the corner elements -1 by $-\alpha$ which can be set equal to zero at the end, for a comparison. Adding to $-\epsilon^2\nabla\bar{\nabla}$ a time-dependent frequency matrix we then consider the fluctuation matrix

$$-\epsilon^2\nabla\bar{\nabla} + \epsilon^2\Omega^2 = \begin{pmatrix} 2 + \epsilon^2\Omega_{N+1}^2 & -1 & 0 & \dots & 0 & -\alpha \\ -1 & 2 + \epsilon^2\Omega_N^2 & -1 & \dots & 0 & 0 \\ \vdots & & & & & \vdots \\ -\alpha & 0 & 0 & \dots & -1 & 2 + \epsilon^2\Omega_1^2 \end{pmatrix}. \quad (2.419)$$

Let us denote the determinant of this $(N+1) \times (N+1)$ matrix by \tilde{D}_{N+1} . Expanding it along the first column, it is found to satisfy the equation

$$\begin{aligned} \tilde{D}_{N+1} &= (2 + \epsilon^2\Omega_{N+1}^2) \\ &\times \det_N \begin{pmatrix} 2 + \epsilon^2\Omega_N^2 & -1 & 0 & \dots & 0 & 0 \\ \vdots & & & & & \vdots \\ 0 & 0 & 0 & \dots & -1 & 2 + \epsilon^2\Omega_1^2 \end{pmatrix} \end{aligned} \quad (2.420)$$

$$\begin{aligned}
& +\det_N \begin{pmatrix} -1 & 0 & 0 & 0 & \dots & 0 & -\alpha \\ -1 & 2 + \epsilon^2 \Omega_{N-1}^2 & -1 & 0 & \dots & 0 & 0 \\ 0 & -1 & 2 + \epsilon^2 \Omega_{N-2}^2 & -1 & \dots & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & 0 & 0 & \dots & -1 & 2 + \epsilon^2 \Omega_1^2 \end{pmatrix} \\
& +(-1)^{N+1} \alpha \det_N \begin{pmatrix} -1 & 0 & 0 & \dots & 0 & -\alpha \\ 2 + \epsilon^2 \Omega_N^2 & -1 & 0 & \dots & 0 & 0 \\ -1 & 2 + \epsilon^2 \Omega_{N-1}^2 & -1 & \dots & 0 & 0 \\ \vdots & & & & & \vdots \\ 0 & 0 & 0 & \dots & 2 + \epsilon^2 \Omega_2^2 & -1 \end{pmatrix}.
\end{aligned}$$

The first determinant was encountered before in Eq. (2.204) (except that there it appeared with $-\epsilon^2 \Omega^2$ instead of $\epsilon^2 \Omega^2$). There it was denoted by D_N , satisfying the difference equation

$$(-\epsilon^2 \bar{\nabla} \nabla + \epsilon^2 \Omega_{N+1}^2) D_N = 0, \quad (2.421)$$

with the initial conditions

$$\begin{aligned}
D_1 &= 2 + \epsilon^2 \Omega_1^2, \\
D_2 &= (2 + \epsilon^2 \Omega_1^2)(2 + \epsilon^2 \Omega_2^2) - 1.
\end{aligned} \quad (2.422)$$

The second determinant in (2.420) can be expanded with respect to its first column yielding

$$-D_{N-1} - \alpha. \quad (2.423)$$

The third determinant is more involved. When expanded along the first column it gives

$$(-1)^N [1 + (2 + \epsilon^2 \Omega_N^2) H_{N-1} - H_{N-2}], \quad (2.424)$$

with the $(N-1) \times (N-1)$ determinant

$$\begin{aligned}
H_{N-1} &\equiv (-1)^{N-1} \\
&\times \det_{N-1} \begin{pmatrix} 0 & 0 & 0 & \dots & 0 & 0 & -\alpha \\ 2 + \epsilon^2 \Omega_{N-1}^2 & -1 & 0 & \dots & 0 & 0 & 0 \\ -1 & 2 + \epsilon^2 \Omega_{N-2}^2 & -1 & \dots & 0 & 0 & 0 \\ \vdots & & & & & & \vdots \\ 0 & 0 & 0 & \dots & -1 & 2 + \epsilon^2 \Omega_2^2 & -1 \end{pmatrix}.
\end{aligned} \quad (2.425)$$

By expanding this along the first column, we find that H_N satisfies the same difference equation as D_N :

$$(-\epsilon^2 \bar{\nabla} \nabla + \epsilon^2 \Omega_{N+1}^2) H_N = 0. \quad (2.426)$$

However, the initial conditions for H_N are different:

$$H_2 = \begin{vmatrix} 0 & -\alpha \\ 2 + \epsilon^2 \Omega_2^2 & -1 \end{vmatrix} = \alpha(2 + \epsilon^2 \Omega_2^2), \quad (2.427)$$

$$\begin{aligned}
H_3 &= - \begin{vmatrix} 0 & 0 & -\alpha \\ 2 + \epsilon^2 \Omega_3^2 & -1 & 0 \\ -1 & 2 + \epsilon^2 \Omega_2^2 & -1 \end{vmatrix} \\
&= \alpha [(2 + \epsilon^2 \Omega_2^2)(2 + \epsilon^2 \Omega_3^2) - 1].
\end{aligned} \quad (2.428)$$

They show that H_N is in fact equal to αD_{N-1} , provided we shift Ω_N^2 by one lattice unit upwards to Ω_{N+1}^2 . Let us indicate this by a superscript $+$, i.e., we write

$$H_N = \alpha D_{N-1}^+. \quad (2.429)$$

Thus we arrive at the equation

$$\begin{aligned} \tilde{D}_{N+1} &= (2 + \epsilon^2 \Omega_N^2) D_N - D_{N-1} - \alpha \\ &\quad - \alpha [1 + (2 + \epsilon^2 \Omega_N^2) \alpha D_{N-2}^+ - \alpha D_{N-3}^+]. \end{aligned} \quad (2.430)$$

Using the difference equations for D_N and D_N^+ , this can be brought to the convenient form

$$\tilde{D}_{N+1} = D_{N+1} - \alpha^2 D_{N-1}^+ - 2\alpha. \quad (2.431)$$

For quantum-mechanical fluctuations with $\alpha = 0$, this reduces to the earlier result in Section 2.3.6. For periodic fluctuations with $\alpha = 1$, the result is

$$\tilde{D}_{N+1} = D_{N+1} - D_{N-1}^+ - 2. \quad (2.432)$$

In the continuum limit, $D_{N+1} - D_{N-1}^+$ tends towards $2\dot{D}_{\text{ren}}$, where $D_{\text{ren}}(\tau) = D_a(t)$ is the imaginary-time version of the Gelfand-Yaglom function in Section 2.4 solving the homogenous differential equation (2.215), with the initial conditions (2.213) and (2.214), or Eqs. (2.228). The corresponding properties are now:

$$[-\partial_\tau^2 + \Omega^2(\tau)] D_{\text{ren}}(\tau) = 0, \quad D_{\text{ren}}(0) = 0, \quad \dot{D}_{\text{ren}}(0) = 1. \quad (2.433)$$

In terms of $D_{\text{ren}}(\tau)$, the determinant is given by the *Gelfand-Yaglom-like* formula

$$\det(-\epsilon^2 \overline{\nabla} \nabla + \epsilon \Omega^2)_T \xrightarrow{\epsilon \rightarrow 0} 2[\dot{D}_{\text{ren}}(\hbar\beta) - 1], \quad (2.434)$$

and the partition function reads

$$Z_\Omega = \frac{1}{\sqrt{2[\dot{D}_{\text{ren}}(\hbar\beta) - 1]}}. \quad (2.435)$$

The result may be checked by going back to the amplitude $(x_b t_b | x_a t_a)$ of Eq. (2.262), continuing it to imaginary times $t = i\tau$, setting $x_b = x_a = x$, and integrating over all x . The result is

$$Z_\Omega = \frac{1}{2\sqrt{\dot{D}_a(t_b) - 1}}, \quad t_b = i\hbar\beta, \quad (2.436)$$

in agreement with (2.435).

As an example, take the harmonic oscillator for which the solution of (2.433) is

$$D_{\text{ren}}(\tau) = \frac{1}{\omega} \sinh \omega \tau \quad (2.437)$$

[the analytically continued (2.216)]. Then

$$2[\dot{D}_{\text{ren}}(\tau) - 1] = 2(\cosh \beta \hbar \omega - 1) = 4 \sinh^2(\beta \hbar \omega / 2), \quad (2.438)$$

and we find the correct partition function:

$$\begin{aligned} Z_\omega &= \left\{ 2[\dot{D}_{\text{ren}}(\tau) - 1] \right\}^{-1/2} \Big|_{\tau=\hbar\beta} \\ &= \frac{1}{2 \sinh(\beta \hbar \omega / 2)}. \end{aligned} \quad (2.439)$$

On a sliced imaginary-time axis, the case of a constant frequency $\Omega^2 \equiv \omega^2$ is solved as follows. From Eq. (2.210) we take the ordinary Gelfand-Yaglom function D_N , and continue it to Euclidean $\tilde{\omega}_e$, yielding the imaginary-time version

$$D_N = \frac{\sinh(N+1)\tilde{\omega}_e\epsilon}{\sinh\tilde{\omega}_e\epsilon}. \quad (2.440)$$

Then we use formula (2.432), which simplifies for a constant $\Omega^2 \equiv \omega^2$ for which $D_{N-1}^+ = D_{N-1}$, and calculate

$$\begin{aligned} \tilde{D}_{N+1} &= \frac{1}{\sinh\tilde{\omega}_e\epsilon} [\sinh(N+2)\tilde{\omega}_e\epsilon - \sinh N\tilde{\omega}_e\epsilon] - 2 \\ &= 2 [\cosh(N+1)\tilde{\omega}_e\epsilon - 1] = 4 \sinh^2[(N+1)\tilde{\omega}_e\epsilon/2]. \end{aligned} \quad (2.441)$$

Inserting this into Eq. (2.386) yields the partition function

$$Z_\omega = \frac{1}{\sqrt{\tilde{D}_{N+1}}} = \frac{1}{2 \sinh(\hbar\tilde{\omega}_e\beta/2)}, \quad (2.442)$$

in agreement with (2.403).

2.12 Functional Measure in Fourier Space

There exists an alternative definition for the quantum-statistical path integral which is useful for some applications (for example in Section 2.13 and in Chapter 5). The limiting product formula (2.410) suggests that instead of summing over all zigzag configurations of paths on a sliced time axis, a path integral may be defined with the help of the Fourier components of the paths on a continuous time axis. As in (2.380), but with a slightly different normalization of the coefficients, we expand these paths here as

$$x(\tau) = x_0 + \eta(\tau) \equiv x_0 + \sum_{m=1}^{\infty} (x_m e^{i\omega_m\tau} + \text{c.c.}), \quad x_0 = \text{real}, \quad x_{-m} \equiv x_m^*. \quad (2.443)$$

Note that the temporal integral over the time-dependent fluctuations $\eta(\tau)$ is zero, $\int_0^{\hbar/k_B T} d\tau \eta(\tau) = 0$, so that the zero-frequency component x_0 is the temporal average of the fluctuating paths:

$$x_0 = \bar{x} \equiv \frac{k_B T}{\hbar} \int_0^{\hbar/k_B T} d\tau x(\tau). \quad (2.444)$$

In contrast to (2.380) which was valid on a sliced time axis and was therefore subject to a restriction on the range of the m -sum, the present sum is unrestricted and runs over *all* Matsubara frequencies $\omega_m = 2\pi m k_B T / \hbar = 2\pi m / \hbar \beta$. In terms of x_m , the Euclidean action of the linear oscillator is

$$\begin{aligned} \mathcal{A}_e &= \frac{M}{2} \int_0^{\hbar/k_B T} d\tau (\dot{x}^2 + \omega^2 x^2) \\ &= \frac{M\hbar}{k_B T} \left[\frac{\omega^2}{2} x_0^2 + \sum_{m=1}^{\infty} (\omega_m^2 + \omega^2) |x_m|^2 \right]. \end{aligned} \quad (2.445)$$

The integration variables of the time-sliced path integral were transformed to the Fourier components x_m in Eq. (2.388). The product of integrals $\prod_n \int_{-\infty}^{\infty} dx(\tau_n)$ turned into the product (2.390) of integrals over real and imaginary parts of x_m . In the continuum limit, the result is

$$\int_{-\infty}^{\infty} dx_0 \prod_{m=1}^{\infty} \int_{-\infty}^{\infty} d \operatorname{Re} x_m \int_{-\infty}^{\infty} d \operatorname{Im} x_m. \quad (2.446)$$

Placing the exponential $e^{-A_e/\hbar}$ with the frequency sum (2.445) into the integrand, the product of Gaussian integrals renders a product of inverse eigenvalues $(\omega_m^2 + \omega^2)^{-1}$ for $m = 1, \dots, \infty$, with some infinite factor. This may be determined by comparison with the known continuous result (2.410) for the harmonic partition function. The infinity is of the type encountered in Eq. (2.183), and must be divided out of the measure (2.446). The correct result (2.408) is obtained from the following measure of integration in Fourier space

$$\oint \mathcal{D}x \equiv \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \prod_{m=1}^{\infty} \left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{d \operatorname{Re} x_m d \operatorname{Im} x_m}{\pi k_B T / M \omega_m^2} \right]. \quad (2.447)$$

The divergences in the product over the factors $(\omega_m^2 + \omega^2)^{-1}$ discussed after Eq. (2.183) are canceled by the factors ω_m^2 in the measure. It will be convenient to introduce a short-hand notation for the measure on the right-hand side, writing it as

$$\oint \mathcal{D}x \equiv \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \oint \mathcal{D}'x. \quad (2.448)$$

The denominator of the x_0 -integral is the length scale $l_e(\hbar\beta)$ associated with β defined in Eq. (2.353).

Then we calculate

$$\begin{aligned} Z_{\omega}^{x_0} &\equiv \oint \mathcal{D}'x e^{-A_e/\hbar} = \prod_{m=1}^{\infty} \left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{d \operatorname{Re} x_m d \operatorname{Im} x_m}{\pi k_B T / M \omega_m^2} \right] e^{-M\hbar[\omega^2 x_0^2/2 + \sum_{m=1}^{\infty} (\omega_m^2 + \omega^2)|x_m|^2]/k_B T} \\ &= e^{-M\omega^2 x_0^2/2k_B T} \prod_{m=1}^{\infty} \left[\frac{\omega_m^2 + \omega^2}{\omega_m^2} \right]^{-1}. \end{aligned} \quad (2.449)$$

The final integral over the zero-frequency component x_0 yields the partition function

$$Z_{\omega} = \oint \mathcal{D}x e^{-A_e/\hbar} = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} Z_{\omega}^{x_0} = \frac{k_B T}{\hbar\omega} \prod_{m=1}^{\infty} \left[\frac{\omega_m^2 + \omega^2}{\omega_m^2} \right]^{-1}, \quad (2.450)$$

as in (2.410).

The same measure can be used for the more general amplitude (2.414), as is obvious from (2.416). With the predominance of the kinetic term in the measure of path integrals [the divergencies discussed after (2.183) stem only from it], it can

easily be shown that the same measure is applicable to any system with the standard kinetic term.

It is also possible to find a Fourier decomposition of the paths and an associated integration measure for the open-end partition function in Eq. (2.413). We begin by considering the slightly reduced set of all paths satisfying the Neumann boundary conditions

$$\dot{x}(\tau_a) = v_a = 0, \quad \dot{x}(\tau_b) = v_b = 0. \quad (2.451)$$

They have the Fourier expansion

$$x(\tau) = x_0 + \eta(\tau) = x_0 + \sum_{n=1}^{\infty} x_n \cos \nu_n(\tau - \tau_a), \quad \nu_n = n\pi/\beta. \quad (2.452)$$

The frequencies ν_n are the Euclidean version of the frequencies (3.64) for Dirichlet boundary conditions. Let us calculate the partition function for such paths by analogy with the above periodic case by a Fourier decomposition of the action

$$\mathcal{A}_e = \frac{M}{2} \int_0^{\hbar/k_B T} d\tau (\dot{x}^2 + \omega^2 x^2) = \frac{M\hbar}{k_B T} \left[\frac{\omega^2}{2} x_0^2 + \frac{1}{2} \sum_{n=1}^{\infty} (\nu_n^2 + \omega^2) x_n^2 \right], \quad (2.453)$$

and of the measure

$$\begin{aligned} \oint \mathcal{D}x &\equiv \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \prod_{n=1}^{\infty} \left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dx_n}{\pi k_B T / 2M\nu_n^2} \right] \\ &\equiv \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \oint \mathcal{D}'x. \end{aligned} \quad (2.454)$$

We now perform the path integral over all fluctuations at fixed x_0 as in (2.449):

$$\begin{aligned} Z_{\omega}^{N,x_0} &\equiv \oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar} = \prod_{n=1}^{\infty} \left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dx_n}{\pi k_B T / 2M\nu_n^2} \right] e^{-M\hbar[\omega^2 x_0^2/2 + \sum_{n=1}^{\infty} (\nu_n^2 + \omega^2) |x_n|^2]/k_B T} \\ &= e^{-M\omega^2 x_0^2/2k_B T} \prod_{n=1}^{\infty} \left[\frac{\nu_n^2 + \omega^2}{\nu_n^2} \right]^{-1}. \end{aligned} \quad (2.455)$$

Using the product formula (2.183), this becomes

$$Z_{\omega}^{N,x_0} = \sqrt{\frac{\omega\hbar\beta}{\sinh \omega\hbar\beta}} \exp\left(-\beta \frac{M}{2} \omega^2 x_0^2\right). \quad (2.456)$$

The final integral over the zero-frequency component x_0 yields the partition function

$$Z_{\omega}^N = \frac{1}{l_e(\hbar\beta)} \sqrt{\frac{2\pi\hbar}{M\omega}} \frac{1}{\sqrt{\sinh \omega\hbar\beta}}. \quad (2.457)$$

We have replaced the denominator in the prefactor $1/l_e(\hbar\beta)$ by the length scale $1/l_e(\hbar\beta)$ of Eq. (2.353). Apart from this prefactor, the Neumann partition function coincides precisely with the open-end partition function Z_{ω}^{open} in Eq. (2.413).

What is the reason for this coincidence up to a trivial factor, even though the paths satisfying Neumann boundary conditions do *not* comprise all paths with open ends? Moreover, the integrals over the endpoints in the defining equation (2.413) do not force the endpoint *velocities*, but rather endpoint *momenta* to vanish. Indeed, recalling Eq. (2.189) for the time evolution amplitude in momentum space we can see immediately that the partition function with open ends Z_ω^{open} in Eq. (2.413) is identical to the imaginary-time amplitude with vanishing endpoint momenta:

$$Z_\omega^{\text{open}} = (p_b \hbar \beta | p_a 0) \Big|_{p_b=p_a=0}. \quad (2.458)$$

Thus, the sum over all paths with arbitrary open ends is equal to the sum of all paths satisfying Dirichlet boundary conditions in momentum space. Only classically, the vanishing of the endpoint momenta implies the vanishing of the endpoint velocities. From the general discussion of the time-sliced path integral in phase space in Section 2.1 we know that fluctuating paths have $M\dot{x} \neq p$. The fluctuations of the difference are controlled by a Gaussian exponential of the type (2.53). This leads to the explanation of the trivial factor between Z_ω^{open} and Z_ω^{N} . The difference between $M\dot{x}$ and p appears only in the last short-time intervals at the ends. But at short time, the potential does not influence the fluctuations in (2.53). This is the reason why the fluctuations at the endpoints contribute only a trivial overall factor $l_e(\hbar\beta)$ to the partition function Z_ω^{N} .

2.13 Classical Limit

The alternative measure of the last section serves to show, somewhat more convincingly than before, that in the high-temperature limit the path integral representation of any quantum-statistical partition function reduces to the classical partition function as stated in Eq. (2.346). We start out with the Lagrangian formulation (2.376). Inserting the Fourier decomposition (2.443), the kinetic term becomes

$$\int_0^{\hbar\beta} d\tau \frac{M}{2} \dot{x}^2 = \frac{M\hbar}{k_B T} \sum_{m=1}^{\infty} \omega_m^2 |x_m|^2, \quad (2.459)$$

and the partition function reads

$$Z = \oint \mathcal{D}x \exp \left[-\frac{M}{k_B T} \sum_{m=1}^{\infty} \omega_m^2 |x_m|^2 - \frac{1}{\hbar} \int_0^{\hbar/k_B T} d\tau V \left(x_0 + \sum_{m=-\infty}^{\infty}{}' x_m e^{-i\omega_m \tau} \right) \right]. \quad (2.460)$$

The summation symbol with a prime implies the absence of the $m = 0$ -term. The measure is the product (2.447) of integrals of all Fourier components.

We now observe that for large temperatures, the Matsubara frequencies for $m \neq 0$ diverge like $2\pi m k_B T / \hbar$. This has the consequence that the Boltzmann factor for the $x_{m \neq 0}$ fluctuations becomes sharply peaked around $x_m = 0$. The average size of x_m is $\sqrt{k_B T / M / \omega_m} = \hbar / 2\pi m \sqrt{M k_B T}$. If the potential $V \left(x_0 + \sum_{m=-\infty}^{\infty}{}' x_m e^{-i\omega_m \tau} \right)$ is a smooth function of its arguments, we can approximate it by $V(x_0)$ plus terms

containing higher powers of x_m . For large temperatures, these are small on the average and can be ignored. The leading term $V(x_0)$ is time-independent. Hence we obtain in the high-temperature limit

$$Z \xrightarrow{T \rightarrow \infty} \oint \mathcal{D}x \exp \left[-\frac{M}{k_B T} \sum_{m=1}^{\infty} \omega_m^2 |x_m|^2 - \frac{1}{k_B T} V(x_0) \right]. \quad (2.461)$$

The right-hand side is quadratic in the Fourier components x_m . With the measure of integration (2.447), we perform the integrals over x_m and obtain

$$Z \xrightarrow{T \rightarrow \infty} Z_{\text{cl}} = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-V(x_0)/k_B T}. \quad (2.462)$$

This agrees with the classical statistical partition function (2.352).

The derivation reveals an important prerequisite for the validity of the classical limit: It holds only for sufficiently smooth potentials. We shall see in Chapter 8 that for singular potentials such as $-1/|x|$ (Coulomb), $1/|x|^2$ (centrifugal barrier), $1/\sin^2 \theta$ (angular barrier), this condition is not fulfilled and the classical limit is no longer given by (2.462). The particle distribution $\rho(x)$ at a fixed x does not have this problem. It always tends towards the naively expected classical limit (2.354):

$$\rho(x) \xrightarrow{T \rightarrow \infty} Z_{\text{cl}}^{-1} e^{-V(x)/k_B T}. \quad (2.463)$$

The convergence is nonuniform in x , which is the reason why the limit does not always carry over to the integral (2.462). This will be an important point in deriving in Chapter 12 a new path integral formula valid for singular potentials. At first, we shall ignore such subtleties and continue with the conventional discussion valid for smooth potentials.

2.14 Calculation Techniques on Sliced Time Axis via the Poisson Formula

In the previous sections we have used tabulated product formulas such as (2.127), (2.165), (2.173), (2.400), (2.402) to find fluctuation determinants on a finite sliced time axis. With the recent interest in lattice models of quantum field theories, it is useful to possess an efficient calculational technique to derive such product formulas (and related sums). Consider, as a typical example, the quantum-statistical partition function for a harmonic oscillator of frequency ω on a time axis with $N + 1$ slices of thickness ϵ ,

$$Z = \prod_{m=0}^N [2(1 - \cos \omega_m \epsilon) + \epsilon^2 \omega^2]^{-1/2}, \quad (2.464)$$

with the product running over all Matsubara frequencies $\omega_m = 2\pi m k_B T / \hbar$. Instead of dealing with this product it is advantageous to consider the free energy

$$F = -k_B T \log Z = \frac{1}{2} k_B T \sum_{m=0}^N \log [2(1 - \cos \omega_m \epsilon) + \epsilon^2 \omega^2]. \quad (2.465)$$

We now observe that by virtue of Poisson's summation formula (1.205), the sum can be rewritten as the following combination of a sum and an integral:

$$F = \frac{1}{2}k_B T(N+1) \sum_{n=-\infty}^{\infty} \int_0^{2\pi} \frac{d\lambda}{2\pi} e^{i\lambda n(N+1)} \log[2(1 - \cos \lambda) + \epsilon^2 \omega^2]. \quad (2.466)$$

The sum over n squeezes λ to integer multiples of $2\pi/(N+1) = \omega_m \epsilon$ which is precisely what we want.

We now calculate the integrals in (2.466):

$$\int_0^{2\pi} \frac{d\lambda}{2\pi} e^{i\lambda n(N+1)} \log[2(1 - \cos \lambda) + \epsilon^2 \omega^2]. \quad (2.467)$$

For this we rewrite the logarithm of an arbitrary positive argument as the limit

$$\log a = \lim_{\delta \rightarrow 0} \left[- \int_{\delta}^{\infty} \frac{d\tau}{\tau} e^{-\tau a/2} \right] + \log(2\delta) + \gamma, \quad (2.468)$$

where

$$\gamma \equiv -\Gamma'(1)/\Gamma(1) = \lim_{N \rightarrow \infty} \left(\sum_{n=1}^N \frac{1}{n} - \log N \right) \approx 0.5773156649 \dots \quad (2.469)$$

is the Euler-Mascheroni constant. Indeed, the function

$$E_1(x) = \int_x^{\infty} \frac{dt}{t} e^{-t} \quad (2.470)$$

is known as the *exponential integral* with the small- x expansion¹⁹

$$\overline{E_1}(x) = -\gamma - \log x - \sum_{k=1}^{\infty} \frac{(-x)^k}{kk!}. \quad (2.471)$$

With the representation (2.468) for the logarithm, the free energy can be rewritten as

$$F = \frac{1}{2\epsilon} \sum_{n=-\infty}^{\infty} \lim_{\delta \rightarrow 0} \left\{ - \int_{\delta}^{\infty} \frac{d\tau}{\tau} \int_0^{2\pi} \frac{d\lambda}{2\pi} e^{i\lambda n(N+1) - \tau[2(1 - \cos \lambda) + \epsilon^2 \omega^2]/2} - \delta_{n0} [\log(2\delta) + \gamma] \right\}. \quad (2.472)$$

The integral over λ is now performed²⁰ giving rise to a modified Bessel function $I_{n(N+1)}(\tau)$:

$$F = \frac{1}{2\epsilon} \sum_{n=-\infty}^{\infty} \lim_{\delta \rightarrow 0} \left\{ - \int_{\delta}^{\infty} \frac{d\tau}{\tau} I_{n(N+1)}(\tau) e^{-\tau(2 + \epsilon^2 \omega^2)/2} - \delta_{n0} [\log(2\delta) + \gamma] \right\}. \quad (2.473)$$

If we differentiate this with respect to $\epsilon^2 \omega^2 \equiv m^2$, we obtain

$$\frac{\partial F}{\partial m^2} = \frac{1}{4\epsilon} \sum_{n=-\infty}^{\infty} \int_0^{\infty} d\tau I_{n(N+1)}(\tau) e^{-\tau(2+m^2)/2} \quad (2.474)$$

and perform the τ -integral, using the formula valid for $\text{Re } \nu > -1$, $\text{Re } \alpha > \text{Re } \mu$

$$\int_0^{\infty} d\tau I_{\nu}(\mu\tau) e^{-\tau\alpha} = \mu^{\nu} \frac{(\alpha - \sqrt{\alpha^2 - \mu^2})^{-\nu}}{\sqrt{\alpha^2 - \mu^2}} = \mu^{-\nu} \frac{(\alpha - \sqrt{\alpha^2 - \mu^2})^{\nu}}{\sqrt{\alpha^2 - \mu^2}}, \quad (2.475)$$

¹⁹I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 8.214.2.

²⁰I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formulas 8.411.1 and 8.406.1.

to find

$$\frac{\partial F}{\partial m^2} = \frac{1}{2\epsilon} \sum_{n=-\infty}^{\infty} \frac{1}{\sqrt{(m^2+2)^2-4}} \left[\frac{m^2+2-\sqrt{(m^2+2)^2-4}}{2} \right]^{|n|(N+1)}. \quad (2.476)$$

From this we obtain F by integration over m^2+1 . The $n=0$ -term under the sum gives

$$\log[(m^2+2+\sqrt{(m^2+2)^2-4})/2] + \text{const} \quad (2.477)$$

and the $n \neq 0$ -terms:

$$-\frac{1}{|n|(N+1)} [(m^2+2+\sqrt{(m^2+2)^2-4})/2]^{-|n|(N+1)} + \text{const}, \quad (2.478)$$

where the constants of integration can depend on $n(N+1)$. They are adjusted by going to the limit $m^2 \rightarrow \infty$ in (2.473). There the integral is dominated by the small- τ regime of the Bessel functions

$$I_\alpha(z) \sim \frac{1}{|\alpha|!} \left(\frac{z}{2}\right)^\alpha [1 + O(z^2)], \quad (2.479)$$

and the first term in (2.473) becomes

$$\begin{aligned} & -\frac{1}{(|n|(N+1))!} \int_\delta^\infty \frac{d\tau}{\tau} \left(\frac{\tau}{2}\right)^{|n|(N+1)} e^{-\tau m^2/2} \\ & \approx \begin{cases} \log m^2 + \gamma + \log(2\delta) & n=0 \\ -(m^2)^{-|n|(N+1)}/|n|(N+1) & n \neq 0 \end{cases}. \end{aligned} \quad (2.480)$$

The limit $m^2 \rightarrow \infty$ in (2.477), (2.478) gives, on the other hand, $\log m^2 + \text{const}$ and $-(m^2)^{-|n|(N+1)}/|n|(N+1) + \text{const}$, respectively. Hence the constants of integration must be zero. We can therefore write down the free energy for $N+1$ time steps as

$$\begin{aligned} F &= \frac{1}{2\beta} \sum_{m=0}^N \log[2(1 - \cos(\omega_m \epsilon)) + \epsilon^2 \omega^2] \\ &= \frac{1}{2\epsilon} \left\{ \log \left[\left(\epsilon^2 \omega^2 + 2 + \sqrt{(\epsilon^2 \omega^2 + 2)^2 - 4} \right) / 2 \right] \right. \\ & \quad \left. - \frac{2}{N+1} \sum_{n=1}^{\infty} \frac{1}{n} \left[\left(\epsilon^2 \omega^2 + 2 + \sqrt{(\epsilon^2 \omega^2 + 2)^2 - 4} \right) / 2 \right]^{-|n|(N+1)} \right\}. \end{aligned} \quad (2.481)$$

Here it is convenient to introduce the parameter

$$\epsilon \tilde{\omega}_e \equiv \log \left\{ \left[\epsilon^2 \omega^2 + 2 + \sqrt{(\epsilon^2 \omega^2 + 2)^2 - 4} \right] / 2 \right\}, \quad (2.482)$$

which satisfies

$$\cosh(\epsilon \tilde{\omega}_e) = (\epsilon^2 \omega^2 + 2)/2, \quad \sinh(\epsilon \tilde{\omega}_e) = \sqrt{(\epsilon^2 \omega^2 + 2)^2 - 4}/2, \quad (2.483)$$

or

$$\sinh(\epsilon \tilde{\omega}_e/2) = \epsilon \omega/2.$$

Thus it coincides with the parameter introduced in (2.399), which brings the free energy (2.481) to the simple form

$$\begin{aligned} F &= \frac{\hbar}{2} \left[\tilde{\omega}_e - \frac{2}{\epsilon(N+1)} \sum_{n=1}^{\infty} \frac{1}{n} e^{-\epsilon \tilde{\omega}_e n(N+1)} \right] \\ &= \frac{1}{2} [\hbar \tilde{\omega}_e + 2k_B T \log(1 - e^{-\beta \hbar \tilde{\omega}_e})] \\ &= \frac{1}{\beta} \log [2 \sinh(\beta \hbar \tilde{\omega}_e/2)], \end{aligned} \quad (2.484)$$

whose continuum limit is

$$F \stackrel{\epsilon \rightarrow 0}{=} \frac{1}{\beta} \log [2 \sinh (\beta \hbar \omega / 2)] = \frac{\hbar \omega}{2} + \frac{1}{\beta} \log (1 - e^{-\beta \hbar \omega}). \quad (2.485)$$

2.15 Field-Theoretic Definition of Harmonic Path Integrals by Analytic Regularization

A slight modification of the calculational techniques developed in the last section for the quantum partition function of a harmonic oscillator can be used to define the harmonic path integral in a way which neither requires time slicing, as in the original Feynman expression (2.66), nor a precise specification of the integration measure in terms of Fourier components, as in Section 2.12. The path integral for the partition function

$$Z_\omega = \oint \mathcal{D}x e^{-\int_0^{\hbar\beta} M[x^2(\tau) + \omega^2 x^2(\tau)]/2} = \oint \mathcal{D}x e^{-\int_0^{\hbar\beta} Mx(\tau)[- \partial_\tau^2 + \omega^2]x(\tau)/2} \quad (2.486)$$

is formally evaluated as

$$Z_\omega = \frac{1}{\sqrt{\text{Det}(-\partial_\tau^2 + \omega^2)}} = e^{-\frac{1}{2} \text{Tr} \log(-\partial_\tau^2 + \omega^2)}. \quad (2.487)$$

Since the determinant of an operator is the product of all its eigenvalues, we may write, again formally,

$$Z_\omega = \prod_{\omega'} \frac{1}{\sqrt{\omega'^2 + \omega^2}}. \quad (2.488)$$

The product runs over an infinite set of quantities which grow with ω'^2 , thus being certainly divergent. It may be turned into a divergent sum by rewriting Z_ω as

$$Z_\omega \equiv e^{-F_\omega/k_B T} = e^{-\frac{1}{2} \sum_{\omega'} \log(\omega'^2 + \omega^2)}. \quad (2.489)$$

This expression has two unsatisfactory features. First, it requires a proper definition of the formal sum over a continuous set of frequencies. Second, the logarithm of the dimensionful arguments $\omega_m^2 + \omega^2$ must be turned into a meaningful expression. The latter problem would be removed if we were able to exchange the logarithm by $\log[(\omega'^2 + \omega^2)/\omega^2]$. This would require the formal sum $\sum_{\omega'} \log \omega^2$ to vanish. We shall see below in Eq. (2.514) that this is indeed one of the pleasant properties of analytic regularization.

At finite temperatures, the periodic boundary conditions along the imaginary-time axis make the frequencies ω' in the spectrum of the differential operator $-\partial_\tau^2 + \omega^2$ discrete, and the sum in the exponent of (2.489) becomes a sum over all Matsubara frequencies $\omega_m = 2\pi k_B T/\hbar$ ($m = 0, \pm 1, \pm 2, \dots$):

$$Z_\omega = \exp \left[-\frac{1}{2} \sum_{m=-\infty}^{\infty} \log(\omega_m^2 + \omega^2) \right]. \quad (2.490)$$

For the free energy $F_\omega \equiv (1/\beta) \log Z_\omega$, this implies

$$F_\omega = \frac{1}{2\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) \Big|_{\text{per}} = \frac{1}{2\beta} \sum_{m=-\infty}^{\infty} \log(\omega_m^2 + \omega^2). \quad (2.491)$$

where the subscript per emphasizes the periodic boundary conditions in the τ -interval $(0, \hbar\beta)$.

2.15.1 Zero-Temperature Evaluation of the Frequency Sum

In the limit $T \rightarrow 0$, the sum in (2.491) goes over into an integral, and the free energy becomes

$$F_\omega \equiv \frac{1}{2\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) \Big|_{\pm\infty} = \frac{\hbar}{2} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log(\omega'^2 + \omega^2), \quad (2.492)$$

where the subscript $\pm\infty$ indicates the vanishing boundary conditions of the eigenfunctions at $\tau = \pm\infty$. Thus, at low temperature, we can replace the frequency sum in the exponent of (2.489) by

$$\sum_{\omega'} \xrightarrow{T \rightarrow 0} \hbar\beta \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi}. \quad (2.493)$$

This could have been expected on the basis of Planck's rules for the phase space invoked earlier on p. 97 to explain the measure of path integration. According to these rules, the volume element in the phase space of energy and time has the measure $\int dt dE/h = \int dt d\omega/2\pi$. If the integrand is independent of time, the temporal integral produces an overall factor, which for the imaginary-time interval $(0, \hbar\beta)$ of statistical mechanics is equal to $\hbar\beta = \hbar/k_B T$, thus explaining the integral version of the sum (2.493).

The integral on the right-hand side of (2.492) diverges at large ω' . This is called an *ultraviolet divergence* (UV-divergence), alluding to the fact that the ultraviolet regime of light waves contains the high frequencies of the spectrum.

The important observation is now that the divergent integral (2.492) can be made finite by a mathematical technique called *analytic regularization*.²¹ This is based on rewriting the logarithm $\log(\omega'^2 + \omega^2)$ in the derivative form:

$$\log(\omega'^2 + \omega^2) = - \left. \frac{d}{d\epsilon} (\omega'^2 + \omega^2)^{-\epsilon} \right|_{\epsilon=0}. \quad (2.494)$$

Equivalently, we may obtain the logarithm from an $\epsilon \rightarrow 0$ -limit of the function

$$l_{\text{MS}}(\epsilon) = -\frac{1}{\epsilon} (\omega'^2 + \omega^2)^{-\epsilon} + \frac{1}{\epsilon}. \quad (2.495)$$

²¹G. 't Hooft and M. Veltman, Nucl. Phys. B 44, 189 (1972). Analytic regularization is at present the only method that allows to renormalize nonabelian gauge theories without destroying gauge invariance. See also the review by G. Leibbrandt, Rev. Mod. Phys. 74, 843 (1975).

The subtraction of the pole term $1/\epsilon$ is commonly referred to a *minimal subtraction*. Indicating this process by a subscript MS, we may write

$$l_{\text{MS}}(\epsilon) = -\frac{1}{\epsilon}(\omega'^2 + \omega^2)^{-\epsilon} \Big|_{\text{MS}, \epsilon \rightarrow 0}. \quad (2.496)$$

Using the derivative formula (2.494), the trace of the logarithm in the free energy (2.492) takes the form

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{d}{d\epsilon} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} (\omega'^2 + \omega^2)^{-\epsilon} \Big|_{\epsilon=0}. \quad (2.497)$$

We now set up a useful integral representation, due to Schwinger, for a power $a^{-\epsilon}$ generalizing (2.468). Using the defining integral representation for the Gamma function

$$\int_0^{\infty} \frac{d\tau}{\tau} \tau^\mu e^{-\tau\omega^2} = \omega^{-\mu/2} \Gamma(\mu), \quad (2.498)$$

the desired generalization is

$$a^{-\epsilon} = \frac{1}{\Gamma(\epsilon)} \int_0^{\infty} \frac{d\tau}{\tau} \tau^\epsilon e^{-\tau a}. \quad (2.499)$$

This allows us to re-express (2.497) as

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{d}{d\epsilon} \frac{1}{\Gamma(\epsilon)} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \int_0^{\infty} \frac{d\tau}{\tau} \tau^\epsilon e^{-\tau(\omega'^2 + \omega^2)} \Big|_{\epsilon=0}. \quad (2.500)$$

As long as ϵ is larger than zero, the τ -integral converges absolutely, so that we can interchange the τ - and ω' -integrations, and obtain

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{d}{d\epsilon} \frac{1}{\Gamma(\epsilon)} \int_0^{\infty} \frac{d\tau}{\tau} \tau^\epsilon \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{-\tau(\omega'^2 + \omega^2)} \Big|_{\epsilon=0}. \quad (2.501)$$

At this point we can perform the Gaussian integral over ω' using formula (1.338), and find

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{d}{d\epsilon} \frac{1}{\Gamma(\epsilon)} \int_0^{\infty} \frac{d\tau}{\tau} \tau^\epsilon \frac{1}{2\sqrt{\tau\pi}} e^{-\tau\omega^2} \Big|_{\epsilon=0}. \quad (2.502)$$

For small ϵ , the τ -integral is divergent at the origin. It can, however, be defined by an analytic continuation of the integral starting from the regime $\epsilon > 1/2$, where it converges absolutely, to $\epsilon = 0$. The continuation must avoid the pole at $\epsilon = 1/2$. Fortunately, this continuation is trivial since the integral can be expressed in terms of the Gamma function, whose analytic properties are well-known. Using the integral formula (2.498), we obtain

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{1}{2\sqrt{\pi}} \omega^{1-2\epsilon} \frac{d}{d\epsilon} \frac{1}{\Gamma(\epsilon)} \Gamma(\epsilon - 1/2) \Big|_{\epsilon=0}. \quad (2.503)$$

The right-hand side has to be continued analytically from $\epsilon > 1/2$ to $\epsilon = 0$. This is easily done using the defining property of the Gamma function $\Gamma(x) = \Gamma(1+x)/x$, from which we find $\Gamma(-1/2) = -2\Gamma(1/2) = -2\sqrt{\pi}$, and $1/\Gamma(\epsilon) \approx \epsilon/\Gamma(1+\epsilon) \approx \epsilon$. The derivative with respect to ϵ leads to the free energy of the harmonic oscillator at low temperature via analytic regularization:

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log(\omega'^2 + \omega^2) = \omega, \quad (2.504)$$

so that the free energy of the oscillator at zero-temperature becomes

$$F_\omega = \frac{\hbar\omega}{2}. \quad (2.505)$$

This agrees precisely with the result obtained from the lattice definition of the path integral in Eq. (2.407), or from the path integral (3.808) with the Fourier measure (2.447).

With the above procedure in mind, we shall often use the sloppy formula expressing the derivative of Eq. (2.499) at $\epsilon = 0$:

$$\log a = - \int_0^\infty \frac{d\tau}{\tau} e^{-\tau a}. \quad (2.506)$$

This formula differs from the correct one by a minimal subtraction and can be used in all calculations with analytic regularization. Its applicability is based on the possibility of dropping the frequency integral over $1/\epsilon$ in the alternative correct expression

$$\frac{1}{\hbar\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = -\frac{1}{\epsilon} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \left[\frac{1}{\epsilon} (\omega'^2 + \omega^2)^{-\epsilon} - \frac{1}{\epsilon} \right]_{\epsilon \rightarrow 0}. \quad (2.507)$$

In fact, within analytic regularization one may set all integrals over arbitrary pure powers of the frequency equal to zero:

$$\int_0^\infty d\omega' (\omega')^\alpha = 0 \quad \text{for all } \alpha. \quad (2.508)$$

This is known as *Veltman's rule*.²² It is a special limit of a frequency integral which is a generalization of the integral in (2.497):

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \frac{(\omega'^2)^\gamma}{(\omega'^2 + \omega^2)^\epsilon} = \frac{\Gamma(\gamma + 1/2)}{2\pi\Gamma(\epsilon)} (\omega^2)^{\gamma+1/2-\epsilon}. \quad (2.509)$$

This equation may be derived by rewriting the left-hand side as

$$\frac{1}{\Gamma(\epsilon)} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} (\omega'^2)^\gamma \int_0^\infty \frac{d\tau}{\tau} \tau^\epsilon e^{-\tau(\omega'^2 + \omega^2)}. \quad (2.510)$$

²²See the textbook H. Kleinert and V. Schulte-Frohlinde, *Critical Properties of ϕ^4 -Theories*, World Scientific, Singapore, 2001 (<http://www.physik.fu-berlin.de/~kleinert/b8>).

The integral over ω' is performed as follows:

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} (\omega'^2)^\gamma e^{-\tau(\omega'^2 + \omega^2)} = \frac{1}{2\pi} \int_0^{\infty} \frac{d\omega'^2}{\omega'^2} (\omega'^2)^{\gamma+1/2} e^{-\tau(\omega'^2 + \omega^2)} = \frac{\tau^{-\gamma-1/2}}{2\pi} \Gamma(\gamma + 1/2), \quad (2.511)$$

leading to a τ -integral in (2.510)

$$\int_0^{\infty} \frac{d\tau}{\tau} \tau^{\epsilon-\gamma-1/2} e^{-\tau\omega^2} = (\omega^2)^{\gamma+1/2+\epsilon}, \quad (2.512)$$

and thus to the formula (2.509). The Veltman rule (2.508) follows from this directly in the limit $\epsilon \rightarrow 0$, since $1/\Gamma(\epsilon) \rightarrow 0$ on the right-hand side. This implies that the subtracted $1/\epsilon$ term in (2.507) gives no contribution.

The vanishing of all integrals over pure powers by Veltman's rule (2.508) was initially postulated in the process of developing a finite quantum field theory of weak and electromagnetic interactions. It has turned out to be extremely useful for the calculation of critical exponents of second-order phase transitions from field theories.²²

An important consequence of Veltman's rule is to make the logarithms of dimensionful arguments in the partition functions (2.489) and the free energy (2.491) meaningful quantities. First, since $\int d(\omega'/2\pi) \log \omega^2 = 0$, we can divide the argument of the logarithm in (2.492) by ω^2 without harm, and make them dimensionless. At finite temperatures, we use the equality of the sum and the integral over an ω_m -independent quantity c

$$k_B T \sum_{m=-\infty}^{\infty} c = \int_{-\infty}^{\infty} \frac{d\omega_m}{2\pi} c \quad (2.513)$$

to show that also

$$k_B T \sum_{m=-\infty}^{\infty} \log \omega^2 = 0, \quad (2.514)$$

so that we have, as a consequence of Veltman's rule, that the Matsubara frequency sum over the constant $\log \omega^2$ vanishes for all temperatures. For this reason, also the argument of the logarithm in the free energy (2.491) can be divided by ω^2 without change, thus becoming dimensionless.

2.15.2 Finite-Temperature Evaluation of the Frequency Sum

At finite temperature, the free energy contains an additional term consisting of the difference between the Matsubara sum and the frequency integral

$$\Delta F_\omega = \frac{k_B T}{2} \sum_{m=-\infty}^{\infty} \log \left(\frac{\omega_m^2}{\omega^2} + 1 \right) - \frac{\hbar}{2} \int_{-\infty}^{\infty} \frac{d\omega_m}{2\pi} \log \left(\frac{\omega_m^2}{\omega^2} + 1 \right), \quad (2.515)$$

where we have used dimensionless logarithms as discussed at the end of the last subsection. The sum is conveniently split into a subtracted, manifestly convergent expression

$$\Delta_1 F_\omega = k_B T \sum_{m=1}^{\infty} \left[\log \left(\frac{\omega_m^2}{\omega^2} + 1 \right) - \log \frac{\omega_m^2}{\omega^2} \right] = k_B T \sum_{m=1}^{\infty} \log \left(1 + \frac{\omega^2}{\omega_m^2} \right), \quad (2.516)$$

and a divergent sum

$$\Delta_2 F_\omega = k_B T \sum_{m=1}^{\infty} \log \frac{\omega_m^2}{\omega^2}. \quad (2.517)$$

The convergent part is most easily evaluated. Taking the logarithm of the product in Eq. (2.408) and recalling (2.409), we find

$$\prod_{m=1}^{\infty} \left(1 + \frac{\omega^2}{\omega_m^2} \right) = \frac{\sinh(\beta \hbar \omega / 2)}{\beta \hbar \omega / 2}, \quad (2.518)$$

and therefore

$$\Delta F_1 = \frac{1}{\beta} \log \frac{\sinh(\beta \hbar \omega / 2)}{\beta \hbar \omega / 2}. \quad (2.519)$$

The divergent sum (2.517) is calculated by analytic regularization as follows: We rewrite

$$\sum_{m=1}^{\infty} \log \frac{\omega_m^2}{\omega^2} = - \left[2 \frac{d}{d\epsilon} \sum_{m=1}^{\infty} \left(\frac{\omega_m}{\omega} \right)^{-\epsilon} \right]_{\epsilon \rightarrow 0} = - \left[2 \frac{d}{d\epsilon} \left(\frac{2\pi}{\beta \hbar \omega} \right)^{-\epsilon} \sum_{m=1}^{\infty} m^{-\epsilon} \right]_{\epsilon \rightarrow 0}, \quad (2.520)$$

and express the sum over $m^{-\epsilon}$ in terms of Riemann's zeta function

$$\zeta(z) = \sum_{m=1}^{\infty} m^{-z}. \quad (2.521)$$

This sum is well defined for $z > 1$, and can be continued analytically into the entire complex z -plane. The only singularity of this function lies at $z = 1$, where in the neighborhood $\zeta(z) \approx 1/z$. At the origin, $\zeta(z)$ is regular, and satisfies²³

$$\zeta(0) = -1/2, \quad \zeta'(0) = -\frac{1}{2} \log 2\pi, \quad (2.522)$$

such that we may approximate

$$\zeta(z) \approx -\frac{1}{2} (2\pi)^z, \quad z \approx 0. \quad (2.523)$$

Hence we find

$$\sum_{m=1}^{\infty} \log \frac{\omega_m^2}{\omega^2} = - \left[2 \frac{d}{d\epsilon} \left(\frac{2\pi}{\beta \hbar \omega} \right)^{-\epsilon} \zeta(\epsilon) \right]_{\epsilon \rightarrow 0} = \frac{d}{d\epsilon} (\beta \hbar \omega)^\epsilon \Big|_{\epsilon \rightarrow 0} = \log \hbar \omega \beta. \quad (2.524)$$

²³I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 9.541.4.

thus determining $\Delta_2 F_\omega$ in Eq. (2.517).

By combining this with (2.519) and the contribution $-\hbar\omega/2$ from the integral (2.515), the finite-temperature part (2.491) of the free energy becomes

$$\Delta F_\omega = \frac{1}{\beta} \log(1 - e^{-\hbar\beta\omega}). \quad (2.525)$$

Together with the zero-temperature free energy (2.505), this yields the dimensionally regularized sum formula

$$\begin{aligned} F_\omega &= \frac{1}{2\beta} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = \frac{1}{2\beta} \sum_{m=-\infty}^{\infty} \log(\omega_m^2 + \omega^2) = \frac{\hbar\omega}{2} + \frac{1}{\beta} \log(1 - e^{-\hbar\omega/k_B T}) \\ &= \frac{1}{\beta} \log \left(2 \sinh \frac{\hbar\omega\beta}{2} \right), \end{aligned} \quad (2.526)$$

in agreement with the properly normalized free energy (2.485) at all temperatures.

Note that the property of the zeta function $\zeta(0) = -1/2$ in Eq. (2.522) leads once more to our earlier result (2.514) that the Matsubara sum of a constant c vanishes:

$$\sum_{m=-\infty}^{\infty} c = \sum_{m=-\infty}^{-1} c + c + \sum_{m=1}^{\infty} c = 0, \quad (2.527)$$

since

$$\sum_{m=1}^{\infty} 1 = \sum_{m=-1}^{-\infty} 1 = \zeta(0) = -1/2. \quad (2.528)$$

As mentioned before, this allows us to divide ω^2 out of the logarithms in the sum in Eq. (2.526) and rewrite this sum as

$$\frac{1}{2\beta} \sum_{m=-\infty}^{\infty} \log \left(\frac{\omega_m^2}{\omega^2} + 1 \right) = \frac{1}{\beta} \sum_{m=1}^{\infty} \log \left(\frac{\omega_m^2}{\omega^2} + 1 \right) \quad (2.529)$$

2.15.3 Quantum-Mechanical Harmonic Oscillator

This observation leads us directly to the analogous quantum-mechanical discussion. Starting from the fluctuation factor (2.91) of the free particle which can formally be written as

$$F_0(\Delta t) = \int \mathcal{D}\delta x(t) \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \delta x (-\partial_t^2) \delta x \right] = \frac{1}{\sqrt{2\pi\hbar i \Delta t / M}}, \quad (2.530)$$

where $\Delta t \equiv t_b - t_a$ [recall (2.130)]. The path integral of the harmonic oscillator has the fluctuation factor [compare (2.188)]

$$F_\omega(\Delta t) = F_0(\Delta t) \left[\frac{\text{Det}(-\partial_t^2 - \omega^2)}{\text{Det}(-\partial_t^2)} \right]^{-1/2}. \quad (2.531)$$

The ratio of the determinants has the Fourier decomposition

$$\frac{\text{Det}(-\partial_t^2 - \omega^2)}{\text{Det}(-\partial_t^2)} = \exp \left\{ \sum_{n=1}^{\infty} \left[\log(\nu_n^2 - \omega^2) - \log \nu_n^2 \right] \right\}, \quad (2.532)$$

where $\nu_n = n\pi/\Delta t$ [recall (2.115)], and was calculated in Eq. (2.188) to be

$$\frac{\text{Det}(-\partial_t^2 - \omega^2)}{\text{Det}(-\partial_t^2)} = \frac{\sin \omega \Delta t}{\omega \Delta t}. \quad (2.533)$$

This result can be reproduced with the help of formulas (2.529) and (2.526). We replace β by $2\Delta t$, and use again $\sum_n 1 = \zeta(0) = -1/2$ to obtain

$$\begin{aligned} \text{Det}(-\partial_t^2 - \omega^2) &= \sum_{n=1}^{\infty} \log(\nu_n^2 + \omega^2) \Big|_{\omega \rightarrow i\omega} = \sum_{n=1}^{\infty} \left[\log \left(\frac{\nu_n^2}{\omega^2} + 1 \right) + \log \omega^2 \right] \Big|_{\omega \rightarrow i\omega} \\ &= \left[\sum_{n=1}^{\infty} \log \left(\frac{\nu_n^2}{\omega^2} + 1 \right) - \frac{1}{2} \log \omega^2 \right] \Big|_{\omega \rightarrow i\omega} = \log \left(2 \frac{\sin \omega \Delta t}{\omega} \right). \end{aligned} \quad (2.534)$$

For $\omega = 0$ this reproduces Formula (2.524). Inserting this and (2.534) into (2.532), we recover the result (2.533). Thus we find the amplitude

$$(x_b t_b | x_a t_a) = \frac{1}{\sqrt{\pi i/M}} \text{Det}^{-1/2}(-\partial_t^2 - \omega^2) e^{iA_{cl}/\hbar} = \frac{1}{\sqrt{\pi i/M}} \sqrt{\frac{\omega}{2 \sin \omega \Delta t}} e^{iA_{cl}/\hbar}, \quad (2.535)$$

in agreement with (2.175).

2.15.4 Tracelog of the First-Order Differential Operator

The trace of the logarithm in the free energy (2.492) can obviously be split into two terms

$$\text{Tr} \log(-\partial_\tau^2 + \omega^2) = \text{Tr} \log(\partial_\tau + \omega) + \text{Tr} \log(-\partial_\tau + \omega). \quad (2.536)$$

Since the left-hand side is equal to $\beta \hbar \omega$ by (2.504), and the two integrals must be the same, we obtain the low-temperature result

$$\begin{aligned} \text{Tr} \log(\partial_\tau + \omega) &= \text{Tr} \log(-\partial_\tau + \omega) = \hbar \beta \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \log(-i\omega' + \omega) = \hbar \beta \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} \log(i\omega' + \omega) \\ &= \frac{\hbar \beta \omega}{2}. \end{aligned} \quad (2.537)$$

The same result could be obtained from analytic continuation of the integrals over $\partial_\epsilon(\pm i\omega' + \omega)^\epsilon$ to $\epsilon = 0$.

For a finite temperature, we may use Eq. (2.526) to find

$$\text{Tr} \log(\partial_\tau + \omega) = \text{Tr} \log(-\partial_\tau + \omega) = \frac{1}{2} \text{Tr} \log(-\partial_\tau^2 + \omega^2) = \log \left(2 \sinh \frac{\beta \hbar \omega}{2} \right), \quad (2.538)$$

which reduces to (2.537) for $T \rightarrow 0$.

The result is also the same if there is an extra factor i in the argument of the trancelog. To see this we consider the case of time-independent frequency where Veltman's rule (2.508) tells us that it does not matter whether one evaluates integrals over $\log(i\omega' \mp \omega)$ or over $\log(\omega' \pm i\omega)$.

Let us also replace ω' by $i\omega'$ in the zero-temperature trancelog (2.504) of the second-order differential operator $(-\partial_\tau^2 + \omega^2)$. Then we rotate the contour of integration clockwise in the complex plane to find

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log(-\omega'^2 + \omega^2 - i\eta) = \omega, \quad \omega \geq 0, \quad (2.539)$$

where an infinitesimal positive η prescribes how to bypass the singularities at $\omega' = \pm\omega \mp i\eta$ along the rotated contour of integration. Recall the discussion of the $i\eta$ -prescription in Section 3.3. The integral (2.539) can be split into the integrals

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log[\omega' \pm (\omega - i\eta)] = i \frac{\omega}{2}, \quad \omega \geq 0. \quad (2.540)$$

Hence formula (2.537) can be generalized to arbitrary complex frequencies $\omega = \omega_R + i\omega_I$ as follows:

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log(\omega' \pm i\omega) = \mp \epsilon(\omega_R) \frac{\omega}{2}, \quad (2.541)$$

and

$$\int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} \log(\omega' \pm \omega) = -i\epsilon(\omega_I) \frac{\omega}{2}, \quad (2.542)$$

where $\epsilon(x) = \Theta(x) - \Theta(-x) = x/|x|$ is the antisymmetric Heaviside function (1.315), which yields the sign of its argument. The formulas (2.541) and (2.542) are the large-time limit of the more complicated sums

$$\frac{k_B T}{\hbar} \sum_{m=-\infty}^{\infty} \log(\omega_m \pm i\omega) = \frac{k_B T}{\hbar} \log \left[2\epsilon(\omega_R) \sinh \frac{\hbar\omega}{2k_B T} \right], \quad (2.543)$$

and

$$\frac{k_B T}{\hbar} \sum_{m=-\infty}^{\infty} \log(\omega_m \pm \omega) = \frac{k_B T}{\hbar} \log \left[-2i\epsilon(\omega_I) \sin \frac{\hbar\omega}{2k_B T} \right]. \quad (2.544)$$

The first expression is periodic in the imaginary part of ω , with period $2\pi k_B T$, the second in the real part. The determinants possess a meaningful large-time limit only if the periodic parts of ω vanish. In many applications, however, the fluctuations will involve sums of logarithms (2.544) and (2.543) with different complex frequencies ω , and only the sum of the imaginary or real parts will have to vanish to obtain a meaningful large-time limit. On these occasions we may use the simplified formulas (2.541) and (2.542). Important examples will be encountered in Section 18.9.2.

In Subsection 3.3.2, Formula (2.538) will be generalized to arbitrary positive time-dependent frequencies $\Omega(\tau)$, where it reads [see (3.133)]

$$\begin{aligned} \text{Tr log} [\pm\partial_\tau + \Omega(\tau)] &= \text{log} \left\{ 2 \sinh \left[\frac{1}{2} \int_0^{\hbar\beta} d\tau'' \Omega(\tau'') \right] \right\} \\ &= \frac{1}{2} \int_0^{\hbar\beta} d\tau'' \Omega(\tau'') + \text{log} \left[1 - e^{-\int_0^{\hbar\beta} d\tau'' \Omega(\tau'')} \right]. \end{aligned} \quad (2.545)$$

2.15.5 Gradient Expansion of the One-Dimensional Tracelog

Formula (2.545) may be used to calculate the trace of the logarithm of a second-order differential equation with arbitrary frequency as a semiclassical expansion. We introduce the Planck constant \hbar and the potential $w(\tau) \equiv \hbar\Omega(\tau)$, and factorize as in (2.536):

$$\text{Det} [-\hbar^2\partial_\tau^2 + w^2(\tau)] = \text{Det} [-\hbar\partial_\tau - \bar{w}(\tau)] \times \text{Det} [\hbar\partial_\tau - \bar{w}(\tau)], \quad (2.546)$$

where the function $\bar{w}(\tau)$ satisfies the *Riccati differential equation*:²⁴

$$\hbar\partial_\tau\bar{w}(\tau) + \bar{w}^2(\tau) = w^2(\tau). \quad (2.547)$$

By solving this we obtain the trace of the logarithm from (2.545):

$$\text{Tr log} [-\hbar^2\partial_\tau^2 + w^2(\tau)] = \text{log} \left\{ 4 \sinh^2 \left[\frac{1}{2\hbar} \int_0^{\hbar\beta} d\tau' \bar{w}(\tau') \right] \right\}. \quad (2.548)$$

The exponential of this yields the functional determinant. For constant $\bar{w}(\tau) = \omega$ this agrees with the result (2.433) of the Gelfand-Yaglom formula for periodic boundary conditions.

This agreement is no coincidence. We can find the solution of any Riccati differential equation if we know how to solve the second-order differential equation (2.433). Imposing the Gelfand-Yaglom boundary conditions in (2.433), we find $D_{\text{ren}}(\tau)$ and from this the functional determinant $2[\dot{D}_{\text{ren}}(\hbar\beta) - 1]$. Comparison with (2.548) shows that the solution of the Riccati differential equation (2.547) is given by

$$\bar{w}(\tau) = 2\hbar\partial_\tau \text{arsinh} \sqrt{[\dot{D}_{\text{ren}}(\tau) - 1]/2}. \quad (2.549)$$

For the harmonic oscillator where $\dot{D}_{\text{ren}}(\tau)$ is equal to (2.437), this leads to the constant $\bar{w}(\tau) = \hbar\omega$, as it should.

If we cannot solve the second-order differential equation (2.433), a solution to the Riccati equation (2.547) can still be found as a power series in \hbar :

$$\bar{w}(\tau) = \sum_{n=0}^{\infty} \bar{w}_n(\tau)\hbar^n, \quad (2.550)$$

²⁴Recall the general form of the Riccati differential equation $y' = f(\tau)y + g(\tau)y^2 + h(\tau)$, which is an inhomogeneous version of the Bernoulli differential equation $y' = f(\tau)y + g(\tau)y^n$ for $n = 2$.

which provides us with a so-called *gradient expansion* of the trace of the logarithm. The lowest-order coefficient function $\bar{w}_0(\tau)$ is obviously equal to $w(\tau)$. The higher ones obey the recursion relation

$$\bar{w}_n(\tau) = -\frac{1}{2w(\tau)} \left(\dot{\bar{w}}_{n-1}(\tau) + \sum_{k=1}^{n-1} \bar{w}_{n-k}(\tau) \bar{w}_k(\tau) \right), \quad n \geq 1. \quad (2.551)$$

These are solved for $n = 0, 1, 2, 3$ by

$$\left\{ \sqrt{v(\tau)}, -\frac{v'(\tau)}{4v(\tau)}, -\frac{5v'(\tau)^2}{32v(\tau)^{5/2}} + \frac{v''(\tau)}{8v(\tau)^{3/2}}, -\frac{15v'(\tau)^3}{64v(\tau)^4} + \frac{9v'(\tau)v''(\tau)}{32v(\tau)^3} - \frac{v^{(3)}(\tau)}{16v(\tau)^2}, \right. \\ \left. -\frac{1105v'(\tau)^4}{2048v(\tau)^{11/2}} + \frac{221v'(\tau)^2v''(\tau)}{256v(\tau)^{9/2}} - \frac{19v''(\tau)^2}{128v(\tau)^{7/2}} - \frac{7v'(\tau)v^{(3)}(\tau)}{32v(\tau)^{7/2}} + \frac{v^{(4)}(\tau)}{32v(\tau)^{5/2}} \right\}, \quad (2.552)$$

where $v(\tau) \equiv w^2(\tau)$. The series can, of course, be trivially extended to any desired orders.

2.15.6 Duality Transformation and Low-Temperature Expansion

There exists another method of calculating the finite-temperature part of the free energy (2.491) which is worth presenting at this place, due to its broad applicability in statistical mechanics. For this we rewrite (2.515) in the form

$$\Delta F_\omega = \frac{k_B T}{2} \left(\sum_{m=-\infty}^{\infty} -\frac{\hbar}{k_B T} \int_{-\infty}^{\infty} \frac{d\omega_m}{2\pi} \right) \log(\omega_m^2 + \omega^2). \quad (2.553)$$

Changing the integration variable to m , this becomes

$$\Delta F_\omega = \frac{k_B T}{2} \left(\sum_{m=-\infty}^{\infty} - \int_{-\infty}^{\infty} dm \right) \log \left[\left(\frac{2\pi k_B T}{\hbar} \right)^2 m^2 + \omega^2 \right]. \quad (2.554)$$

Within analytic regularization, this expression is rewritten with the help of formula (2.506) as

$$\Delta F_\omega = -\frac{k_B T}{2} \int_0^\infty \frac{d\tau}{\tau} \left(\sum_{m=-\infty}^{\infty} - \int_{-\infty}^{\infty} dm \right) e^{-\tau[(2\pi k_B T/\hbar)^2 m^2 + \omega^2]}. \quad (2.555)$$

The duality transformation proceeds by performing the sum over the Matsubara frequencies with the help of Poisson's formula (1.205) as an integral $\int d\mu$ plus by an extra sum over integer numbers n . This brings (2.555) to the form (expressing the temperature in terms of β),

$$\Delta F_\omega = -\frac{1}{2\beta} \int_0^\infty \frac{d\tau}{\tau} \int_{-\infty}^{\infty} d\mu \left(\sum_{n=-\infty}^{\infty} e^{2\pi\mu n i} - 1 \right) e^{-\tau[(2\pi/\hbar\beta)^2 \mu^2 + \omega^2]}. \quad (2.556)$$

The parentheses contain the sum $2 \sum_{n=1}^{\infty} e^{2\pi\mu ni}$. After a quadratic completion of the exponent

$$2\pi\mu ni - \tau \left(\frac{2\pi}{\hbar\beta} \right)^2 \mu^2 = -\tau \left(\frac{2\pi}{\hbar\beta} \right)^2 \left[\mu - i \frac{n\hbar^2\beta^2}{4\pi\tau} \right]^2 - \frac{1}{4\tau} (\hbar\beta n)^2, \quad (2.557)$$

the integral over μ can be performed, with the result

$$\Delta F_\omega = -\frac{\hbar}{2\sqrt{\pi}} \int_0^\infty \frac{d\tau}{\tau} \tau^{-1/2} \sum_{n=1}^{\infty} e^{-(n\hbar\beta)^2/4\tau - \tau\omega^2}. \quad (2.558)$$

Now we may use the integral formula [compare (1.347)]²⁵

$$\int_0^\infty \frac{d\tau}{\tau} \tau^\nu e^{-a^2/\tau - b^2\tau} = 2 \left(\frac{a}{b} \right)^\nu K_\nu(2ab), \quad K_\nu(2ab) = K_{-\nu}(2ab), \quad (2.559)$$

to obtain the sum over modified Bessel functions

$$\Delta F_\omega = -\frac{\hbar\omega}{2\sqrt{\pi}} \sum_{n=1}^{\infty} 2 (n\beta\hbar\omega)^{-1/2} \sqrt{2} K_{1/2}(n\beta\hbar\omega). \quad (2.560)$$

The modified Bessel functions with index 1/2 are particularly simple:

$$K_{1/2}(z) = \sqrt{\frac{\pi}{2z}} e^{-z}. \quad (2.561)$$

Inserting this into (2.560), the sum is a simple geometric one, and may be performed as follows:

$$\Delta F_\omega = -\frac{1}{\beta} \sum_{n=1}^{\infty} \frac{1}{n} e^{-\beta\hbar\omega n} = \frac{1}{\beta} \log(1 - e^{-\beta\hbar\omega}), \quad (2.562)$$

in agreement with the previous result (2.525).

The effect of the duality transformation may be rephrased in another way. It converts the sum over Matsubara frequencies ω_m in (2.516):

$$S(\beta\hbar\omega) = k_B T \sum_{m=1}^{\infty} \log \left(1 + \frac{\omega^2}{\omega_m^2} \right) \quad (2.563)$$

into a sum over the quantum numbers n of the harmonic oscillator:

$$S(\beta\hbar\omega) = \frac{\beta\hbar\omega}{2} - \log \beta\hbar\omega - \sum_{n=1}^{\infty} \frac{1}{n} e^{-n\beta\hbar\omega}. \quad (2.564)$$

The sum (2.563) converges fast at high temperatures, where it can be expanded in powers of ω^2 :

$$S(\beta\hbar\omega) = - \sum_{k=1}^{\infty} \frac{(-1)^k}{k} \left(\sum_{m=1}^{\infty} \frac{1}{m^{2k}} \right) \left[\left(\frac{\beta\hbar\omega}{2\pi} \right)^2 \right]^k. \quad (2.565)$$

²⁵I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formulas 3.471.9 and 8.486.16.

The expansion coefficients are equal to Riemann's zeta function $\zeta(z)$ of Eq. (2.521) at even arguments $z = 2k$, so that we may write

$$S(\beta\hbar\omega) = - \sum_{m=1}^{\infty} \frac{(-1)^k}{k} \zeta(2k) \left(\frac{\beta\hbar\omega}{2\pi} \right)^{2k}. \quad (2.566)$$

At even positive arguments, the values of the zeta function are related to the Bernoulli numbers by²⁶

$$\zeta(2n) = \frac{(2\pi)^{2n}}{2(2n)!} |B_{2n}|. \quad (2.567)$$

The Bernoulli numbers are defined by the expansion

$$\frac{t}{e^t - 1} = \sum_{n=0}^{\infty} B_n \frac{t^n}{n!}. \quad (2.568)$$

The lowest nonzero Bernoulli numbers are $B_0 = 1$, $B_1 = -1/2$, $B_2 = 1/2$, $B_4 = -1/30, \dots$. The Bernoulli numbers determine also the values of the zeta functions at negative odd arguments:

$$\zeta(1 - 2n) = -\frac{B_{2n}}{2n}, \quad (2.569)$$

this being a consequence of the general identity²⁷

$$\zeta(z) = 2^z \pi^{z-1} \sin(\pi z/2) \Gamma(1-z) \zeta(1-z) = 2^{z-1} \pi^z \zeta(1-z) / \Gamma(z) \cos \frac{z\pi}{2}. \quad (2.570)$$

Typical values of $\zeta(z)$ which will be needed here are²⁸

$$\zeta(2) = \frac{\pi^2}{6}, \quad \zeta(4) = \frac{\pi^4}{90}, \quad \zeta(6) = \frac{\pi^6}{945}, \quad \dots, \quad \zeta(\infty) = 1. \quad (2.571)$$

In contrast to the Matsubara frequency sum (2.563) and its expansion (2.566), the dually transformed sum over the quantum numbers n in (2.564) converges rapidly for low temperatures. It converges everywhere except at very large temperatures, where it diverges logarithmically. The precise behavior can be calculated as follows: For large T there exists a large number N which is still much smaller than $1/\beta\hbar\omega$, such that $e^{-\beta\hbar\omega N}$ is close to unity. Then we split the sum as

$$\sum_{n=1}^{\infty} \frac{1}{n} e^{-n\beta\hbar\omega} \approx \sum_{n=1}^{N-1} \frac{1}{n} + \sum_{n=N}^{\infty} \frac{1}{n} e^{-n\beta\hbar\omega}. \quad (2.572)$$

²⁶*ibid.*, Formulas 9.542 and 9.535.

²⁷*ibid.*, Formula 9.535.2.

²⁸Other often-needed values are $\zeta(0) = -1/2$, $\zeta'(0) = -\log(2\pi)/2$, $\zeta(-2n) = 0$, $\zeta(3) \approx 1.202057$, $\zeta(5) \approx 1.036928, \dots$.

Since N is large, the second sum can be approximated by an integral

$$\int_N^\infty \frac{dn}{n} e^{-n\beta\hbar\omega} = \int_{N\beta\hbar\omega}^\infty \frac{dx}{x} e^{-x},$$

which is an exponential integral $E_1(N\beta\hbar\omega)$ of Eq. (2.470) with the large-argument expansion $-\gamma - \log(N\beta\hbar\omega)$ of Eq. (2.471).

The first sum in (2.572) is calculated with the help of the Digamma function

$$\psi(z) \equiv \frac{\Gamma'(z)}{\Gamma(z)}. \quad (2.573)$$

This has an expansion²⁹

$$\psi(z) = -\gamma - \sum_{n=0}^{\infty} \left(\frac{1}{n+z} - \frac{1}{n+1} \right), \quad (2.574)$$

which reduces for integer arguments to

$$\psi(N) = -\gamma + \sum_{n=1}^{N-1} \frac{1}{n}, \quad (2.575)$$

and has the large- z expansion

$$\psi(z) \approx \log z - \frac{1}{2z} - \sum_{n=1}^{\infty} \frac{B_{2n}}{2nz^{2n}}. \quad (2.576)$$

Combining this with (2.471), the logarithm of N cancels, and we find for the sum in (2.572) the large- T behavior

$$\sum_{n=1}^{\infty} \frac{1}{n} e^{-n\beta\hbar\omega} \underset{T \rightarrow \infty}{\approx} -\log \beta\hbar\omega + \mathcal{O}(\beta). \quad (2.577)$$

This cancels the logarithm in (2.564).

The low-temperature series (2.564) can be used to illustrate the power of analytic regularization. Suppose we want to extract from it the large- T behavior, where the sum

$$g(\beta\hbar\omega) \equiv \sum_{n=1}^{\infty} \frac{1}{n} e^{-n\beta\hbar\omega} \quad (2.578)$$

converges slowly. We would like to expand the exponentials in the sum into powers of ω , but this gives rise to sums over positive powers of n . It is possible to make sense of these sums by analytic continuation. For this we introduce a generalization of (2.578):

$$\zeta_\nu(e^{\beta\hbar\omega}) \equiv \sum_{n=1}^{\infty} \frac{1}{n^\nu} e^{-n\beta\hbar\omega}, \quad (2.579)$$

²⁹I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 1.362.1.

which reduces to $g(\beta\hbar\omega)$ for $\nu = 1$. This sum is evaluated by splitting it into an integral over n and a difference between sum and integral:

$$\zeta_\nu(e^{\beta\hbar\omega}) = \int_0^\infty dn \frac{1}{n^\nu} e^{-n\beta\hbar\omega} + \left(\sum_{n=1}^\infty - \int_0^\infty \right) \frac{1}{n^\nu} e^{-n\beta\hbar\omega}. \quad (2.580)$$

The integral is convergent for $\nu < 1$ and yields $\Gamma(1 - \nu) (\beta\hbar\omega)^\nu$ via the integral formula (2.498). For other ν 's it is defined by analytic continuation. The remainder may be expanded sloppily in powers of ω and yields

$$\zeta_\nu(e^{\beta\hbar\omega}) = \int_0^\infty dn \frac{1}{n^\nu} e^{-n\beta\hbar\omega} + \left(\sum_{n=1}^\infty - \int_0^\infty \right) \frac{1}{n^\nu} + \sum_{k=1}^\infty \left[\left(\sum_{n=1}^\infty - \int_0^\infty \right) n^{k-\nu} \right] \frac{(-1)^k}{k!} (\beta\hbar\omega)^k. \quad (2.581)$$

The second term is simply the Riemann zeta function $\zeta(\nu)$ [recall (2.521)]. Since the additional integral vanishes due to Veltman' rule (2.508), the zeta function may also be defined by

$$\left(\sum_{n=1}^\infty - \int_0^\infty \right) \frac{1}{n^\nu} = \zeta(\nu), \quad (2.582)$$

If this formula is applied to the last term in (2.581), we obtain the so-called *Robinson expansion*³⁰

$$\zeta_\nu(e^{\beta\hbar\omega}) = \Gamma(1 - \nu) (\beta\hbar\omega)^{\nu-1} + \zeta(\nu) + \sum_{k=1}^\infty \frac{1}{k!} (-\beta\hbar\omega)^k \zeta(\nu - k). \quad (2.583)$$

This expansion will later play an important role in the discussion of Bose-Einstein condensation [see Eq. (7.38)].

For various applications it is useful to record also the auxiliary formula

$$\left(\sum_{n=1}^\infty - \int_0^\infty \right) \frac{e^{n\beta\hbar\omega}}{n^\nu} = \sum_{k=1}^\infty \frac{1}{k!} (-\beta\hbar\omega)^k \zeta(\nu - k) \equiv \bar{\zeta}_\nu(e^{\beta\hbar\omega}), \quad (2.584)$$

since in the sum minus the integral, the first Robinson terms are absent and the result can be obtained from a naive Taylor expansion of the exponents $e^{n\beta\hbar\omega}$ and the summation formula (2.582).

From (2.583) we can extract the desired sum (2.578) by going to the limit $\nu \rightarrow 1$. Close to the limit, the Gamma function has a pole $\Gamma(1 - \nu) = 1/(1 - \nu) - \gamma + \mathcal{O}(\nu - 1)$. From the identity

$$2^z \Gamma(1 - z) \zeta(1 - z) \sin \frac{\pi z}{2} = \pi^{1-z} \zeta(z) \quad (2.585)$$

and (2.522) we see that $\zeta(\nu)$ behaves near $\nu = 1$ like

$$\zeta(\nu) = \frac{1}{\nu - 1} + \gamma + \mathcal{O}(\nu - 1) = -\Gamma(1 - \nu) + \mathcal{O}(\nu - 1). \quad (2.586)$$

³⁰J.E. Robinson, Phys. Rev. 83, 678 (1951).

Hence the first two terms in (2.583) can be combined to yield for $\nu \rightarrow 1$ the finite result $\lim_{\nu \rightarrow 1} \Gamma(1 - \nu) [(\beta\hbar\omega)^{\nu-1} - 1] = -\log \beta\hbar\omega$. The remaining terms contain in the limit the values $\zeta(0) = -1/2$, $\zeta(-1)$, $\zeta(-2)$, etc. Here we use the property of the zeta function that it vanishes at even negative arguments, and that the function at arbitrary negative argument is related to one at positive argument by the identity (2.585). This implies for the expansion coefficients in (2.583) with $k = 1, 2, 3, \dots$ in the limit $\nu \rightarrow 1$:

$$\zeta(-2p) = 0, \quad \zeta(1 - 2p) = \frac{1}{p}(-1)^p \frac{(2p)!}{(2\pi)^{2p}} \zeta(2p), \quad p = 1, 2, 3, \dots \quad (2.587)$$

Hence we obtain for the expansion (2.583) in the limit $\nu \rightarrow 1$:

$$g(\beta\hbar\omega) = \zeta_1(e^{\beta\hbar\omega}) = -\log \beta\hbar\omega + \frac{\beta\hbar\omega}{2} + \sum_{k=1}^{\infty} \zeta(2k) \frac{(-1)^k}{k!} (\beta\hbar\omega)^{2k}. \quad (2.588)$$

This can now be inserted into Eq. (2.564) and we recover the previous expansion (2.566) for $S(\beta\hbar\omega)$ which was derived there by a proper duality transformation.

It is interesting to observe what goes wrong if we forget the separation (2.580) of the sum into integral plus sum-minus-integral and its regularization. For this we re-expand (2.578) directly, and illegally, in powers of ω . Then we obtain for $\nu = 1$ the formal expansion

$$\zeta_1(e^{\beta\hbar\omega}) = \sum_{p=0}^{\infty} \left(\sum_{n=1}^{\infty} n^{p-1} \right) \frac{(-1)^p}{p!} (\beta\hbar\omega)^p = -\zeta(1) + \sum_{p=1}^{\infty} \zeta(1-p) \frac{(-1)^p}{p!} (\beta\hbar\omega)^p, \quad (2.589)$$

which contains the infinite quantity $\zeta(1)$. The correct result (2.588) is obtained from this by replacing the infinite quantity $\zeta(1)$ by $-\log \beta\hbar\omega$, which may be viewed as a regularized $\zeta_{\text{reg}}(1)$:

$$\zeta(1) \rightarrow \zeta_{\text{reg}}(1) = -\log \beta\hbar\omega. \quad (2.590)$$

The above derivation of the Robinson expansion can be supplemented by a dual version as follows. With the help of Poisson's formula (1.197) we rewrite the sum (2.579) as an integral over n and an auxiliary sum over integer numbers m , after which the integral over n can be performed yielding

$$\begin{aligned} \zeta_{\nu}(e^{\beta\hbar\omega}) &\equiv \sum_{m=-\infty}^{\infty} \int_0^{\infty} dn e^{(2\pi im + \beta\hbar\omega)n} \frac{1}{n^{\nu}} = \Gamma(1 - \nu) (-\beta\hbar\omega)^{\nu-1} \\ &+ \Gamma(1 - \nu) 2 \operatorname{Re} \sum_{m=1}^{\infty} (-\beta\hbar\omega - 2\pi im)^{\nu-1}. \end{aligned} \quad (2.591)$$

The sum can again be expanded in powers of ω

$$\begin{aligned} 2 \operatorname{Re} \sum_{m=1}^{\infty} (-2\pi im)^{\nu-1} \left(1 + \frac{\beta\hbar\omega}{2\pi im} \right)^{\nu-1} \\ = 2 \sum_{k=0}^{\infty} \binom{\nu-1}{k} \cos[(1 - \nu - k)\pi/2] (2\pi)^{\nu-1-k} \zeta(1 - \nu + k) (\beta\hbar\omega)^k. \end{aligned} \quad (2.592)$$

Using the relation (2.585) for zeta-functions, the expansion (2.591) is seen to coincide with (2.579).

Note that the representation (2.591) of $\zeta_\nu(e^{\beta\hbar\omega})$ is a sum over Matsubara frequencies $\omega_m = 2\pi m/\beta$ [recall Eq. (2.381)]:

$$\begin{aligned}\zeta_\nu(e^{\beta\hbar\omega}) &\equiv \sum_{m=-\infty}^{\infty} \int_0^\infty dn e^{(i\omega_m + \hbar\omega)\beta n} \frac{1}{n^\nu} \\ &= \Gamma(1-\nu)(-\beta\hbar\omega)^{\nu-1} \left[1 + 2 \operatorname{Re} \sum_{m=1}^{\infty} (1 + i\omega_m/\hbar\omega)^{\nu-1} \right].\end{aligned}\quad (2.593)$$

The first term coming from the integral over n in (2.580) is associated with the zero Matsubara frequency. This term represents the high-temperature or classical limit of the expansion. The remainder contains the sum over all nonzero Matsubara frequencies, and thus the effect of quantum fluctuations.

It should be mentioned that the first two terms in the low-temperature expansion (2.564) can also be found from the sum (2.563) with the help of the Euler-Maclaurin formula³¹ for a sum over discrete points $t = a + (k + \kappa)\Delta$ of a function $F(t)$ from $k = 0$ to $K \equiv (b - a)/\Delta$:

$$\begin{aligned}\sum_{k=0}^K F(a + k\Delta) &= \frac{1}{\Delta} \int_a^b dt F(t) + \frac{1}{2} [F(a) + F(b)] \\ &\quad + \sum_{p=1}^{\infty} \frac{\Delta^{2p-1}}{(2p)!} B_{2p} [F^{(2p-1)}(b) - F^{(2p-1)}(a)],\end{aligned}\quad (2.594)$$

or, more generally for $t = a + (k + \kappa)\Delta$,

$$\sum_{k=0}^{K-1} F(a + (k + \kappa)\Delta) = \frac{1}{\Delta} \int_a^b dt F(t) + \sum_{p=1}^{\infty} \frac{\Delta^{p-1}}{p!} B_p(\kappa) [F^{(p-1)}(b) - F^{(p-1)}(a)],\quad (2.595)$$

where $B_n(\kappa)$ are the Bernoulli functions defined by a generalization of the expansion (2.568):

$$\frac{te^{\kappa t}}{e^t - 1} = \sum_{n=0}^{\infty} B_n(\kappa) \frac{t^n}{n!}.\quad (2.596)$$

At $\kappa = 0$, the Bernoulli functions start out with the Bernoulli numbers: $B_n(0) = B_n$. The function $B_0(\kappa)$ is equal to 1 everywhere.

Another way of writing formula (2.597) is

$$\sum_{k=0}^{K-1} F(a + (k + \kappa)\Delta) = \frac{1}{\Delta} \int_a^b dt \left[1 + \sum_{p=0}^{\infty} \frac{\Delta^p}{p!} B_p(\kappa) \partial_t^p \right] F(t).\quad (2.597)$$

This implies that a sum over discrete values of a function can be replaced by an integral over a gradient expansion of the function.

³¹M. Abramowitz and I. Stegun, op. cit., Formulas 23.1.30 and 23.1.32.

Using the first Euler-Maclaurin formula (2.594) with $a = \omega_1^2$, $b = \omega_M^2$, and $\Delta = \omega_1$, we find

$$\begin{aligned} \sum_{m=0}^M \left[\log(\omega_m^2 + \omega^2) - \log(\omega_m^2) \right] &= \left\{ \pi \frac{\omega}{\omega_1} + \frac{\omega_m}{\omega_1} \left[\log(\omega_m^2 + \omega^2) - 2 \right] \right\} \Big|_{m=1}^{m=M} - \left\{ \omega = 0 \right\} \Big|_{m=1}^{m=M} \\ &+ \frac{1}{2} \left\{ \log(\omega_1^2 + \omega^2) + \log(\omega_M^2 + \omega^2) \right\} - \left\{ \omega = 0 \right\}. \end{aligned} \quad (2.598)$$

For small T , the leading two terms on the right-hand side are

$$\pi \frac{\omega}{\omega_1} - \frac{1}{2} \log \frac{\omega^2}{\omega_1^2}, \quad (2.599)$$

in agreement with the first two terms in the low-temperature series (2.564). Note that the Euler-Maclaurin formula is unable to recover the exponentially small terms in (2.564), since they are not expandable in powers of T .

The transformation of high- into low-temperature expansions is an important tool for analyzing phase transitions in models of statistical mechanics.³²

2.16 Finite- N Behavior of Thermodynamic Quantities

Thermodynamic fluctuations in Euclidean path integrals are often imitated in computer simulations. These are forced to employ a sliced time axis. It is then important to know in which way the time-sliced thermodynamic quantities converge to their continuum limit. Let us calculate the internal energy E and the specific heat at constant volume C for finite N from (2.484). Using (2.484) we have

$$\begin{aligned} \frac{\partial(\beta\tilde{\omega}_e)}{\partial\beta} &= \frac{\omega}{\cosh(\epsilon\tilde{\omega}_e/2)}, \\ \frac{\partial(\epsilon\tilde{\omega}_e)}{\partial\beta} &= \frac{2}{\beta} \tanh(\epsilon\tilde{\omega}_e/2), \end{aligned} \quad (2.600)$$

and find the internal energy

$$\begin{aligned} E &= \frac{\partial}{\partial\beta}(\beta F) = \frac{\hbar}{2} \coth(\beta\hbar\tilde{\omega}_e/2) \frac{\partial(\beta\tilde{\omega}_e)}{\partial\beta} \\ &= \frac{\hbar\omega}{2} \frac{\coth(\beta\hbar\tilde{\omega}_e/2)}{\cosh(\epsilon\tilde{\omega}_e/2)}. \end{aligned} \quad (2.601)$$

The specific heat at constant volume is given by

$$\begin{aligned} \frac{1}{k_B} C &= -\beta^2 \frac{\partial^2}{\partial\beta^2}(\beta F) = -\beta^2 \frac{\partial}{\partial\beta} E \\ &= \frac{1}{4} \beta^2 \hbar^2 \omega^2 \left[\frac{1}{\sinh^2(\beta\hbar\tilde{\omega}_e/2)} + \coth(\beta\hbar\tilde{\omega}_e/2) \tanh(\epsilon\tilde{\omega}_e/2) \frac{\epsilon}{\hbar\beta} \right] \frac{1}{\cosh^2(\epsilon\tilde{\omega}_e/2)}. \end{aligned} \quad (2.602)$$

Plots are shown in Fig. 2.5 for various N using natural units with $\hbar = 1$, $k_B = 1$. At high

³²See H. Kleinert, *Gauge Fields in Condensed Matter*, Vol. I Superflow and Vortex Lines, World Scientific, Singapore, 1989, pp. 1–742 (<http://www.physik.fu-berlin.de/~kleinert/b1>).

Figure 2.4 Finite-lattice effects in internal energy E and specific heat C at constant volume, as a function of the temperature for various numbers $N + 1$ of time slices. Note the nonuniform way in which the exponential small- T behavior of $C \propto e^{-\omega/T}$ is approached in the limit $N \rightarrow \infty$.

temperatures, F, E , and C are independent of N :

$$F \rightarrow \frac{1}{\beta} \log \beta, \quad (2.603)$$

$$E \rightarrow \frac{1}{\beta} = T, \quad (2.604)$$

$$C \rightarrow 1. \quad (2.605)$$

These limits are a manifestation of the *Dulong-Petit law*: An oscillator has one kinetic and one potential degree of freedom, each carrying an internal energy $T/2$ and a specific heat $1/2$. At low temperatures, on the other hand, E and C are strongly N -dependent (note that since F and E are different at $T = 0$, the entropy of the lattice approximation does not vanish as it must in the continuum limit). Thus, the convergence $N \rightarrow \infty$ is highly nonuniform. After reaching the limit, the specific heat goes to zero for $T \rightarrow 0$ exponentially fast, like $e^{-\omega/T}$. The quantity ω is called *activation energy*.³³ It is the energy difference between the ground state and the first excited state of the harmonic oscillator. For large but finite N , on the other hand, the specific heat has the large value $N + 1$ at $T = 0$. This is due to $\tilde{\omega}_e$ and $\cosh^2(\epsilon\tilde{\omega}_e/2)$ behaving, for a finite N and $T \rightarrow 0$ (where ϵ becomes large) like

$$\begin{aligned} \tilde{\omega}_e &\rightarrow \frac{1}{\epsilon} \log(\epsilon^2 \omega^2), \\ \cosh(\epsilon\tilde{\omega}_e/2) &\rightarrow \epsilon\omega/2. \end{aligned} \quad (2.606)$$

Hence

$$E \xrightarrow{T \rightarrow 0} \frac{1}{\beta} \coth[(N + 1) \log(\epsilon\omega)] \xrightarrow{T \rightarrow 0} 0, \quad (2.607)$$

³³Note that in a D -dimensional solid the lattice vibrations can be considered as an ensemble of harmonic oscillators with energies ω ranging from zero to the Debye frequency. Integrating over the corresponding specific heats with the appropriate density of states, $\int d\omega \omega^{D-1} e^{-\omega/k_B T}$, gives the well-known power law at low temperatures $C \propto T^D$.

$$C \xrightarrow{T \rightarrow 0} N + 1. \quad (2.608)$$

The reason for the nonuniform approach of the $N \rightarrow \infty$ limit is obvious: If we expand (2.484) in powers of ϵ , we find

$$\tilde{\omega}_e = \omega \left(1 - \frac{1}{24} \epsilon^2 \omega^2 + \dots \right). \quad (2.609)$$

When going to low T at finite N the corrections are quite large, as can be seen by writing (2.609), with $\epsilon = \hbar\beta/(N + 1)$, as

$$\tilde{\omega}_e = \omega \left[1 - \frac{1}{24} \frac{\hbar^2 \omega^2}{k_b^2 T^2 (N + 1)^2} + \dots \right]. \quad (2.610)$$

Note that (2.609) contains no corrections of the order ϵ . This implies that the convergence of all thermodynamic quantities in the limit $N \rightarrow \infty, \epsilon \rightarrow 0$ at fixed T is quite fast — one order in $1/N$ faster than we might at first expect [the Trotter formula (2.26) also shows the $1/N^2$ -behavior].

2.17 Time Evolution Amplitude of Freely Falling Particle

The gravitational potential of a particle on the surface of the earth is

$$V(\mathbf{x}) = V_0 + M \mathbf{g} \cdot \mathbf{x}, \quad (2.611)$$

where $-\mathbf{g}$ is the earth's acceleration vector pointing towards the ground, and V_0 some constant. The equation of motion reads

$$\ddot{\mathbf{x}} = -\mathbf{g}, \quad (2.612)$$

which is solved by

$$\mathbf{x} = \mathbf{x}_a + \mathbf{v}_a(t - t_a) + \frac{\mathbf{g}}{2}(t - t_a)^2, \quad (2.613)$$

with the initial velocity

$$\mathbf{v}_a = \frac{\mathbf{x}_b - \mathbf{x}_a}{t_b - t_a} - \frac{\mathbf{g}}{2}(t_b - t_a). \quad (2.614)$$

Inserting this into the action

$$\mathcal{A} = \int_{t_a}^{t_b} dt \left(\frac{M}{2} \dot{\mathbf{x}}^2 - V_0 - \mathbf{g} \cdot \mathbf{x} \right), \quad (2.615)$$

we obtain the classical action

$$\mathcal{A}_{cl} = -V_0(t_b - t_a) + \frac{M(\mathbf{x}_b - \mathbf{x}_a)^2}{2(t_b - t_a)} - \frac{1}{2}(t_b - t_a)\mathbf{g} \cdot (\mathbf{x}_b + \mathbf{x}_a) - \frac{1}{24}(t_b - t_a)^3 \mathbf{g}^2. \quad (2.616)$$

Since the quadratic part of (2.615) is the same as for a free particle, also the fluctuation factor is the same [see (2.130)], and we find the time evolution amplitude

$$\begin{aligned} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle &= \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}} e^{-\frac{i}{\hbar} V_0 (t_b - t_a)} \\ &\times \exp \left\{ \frac{iM}{2\hbar} \left[\frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{t_b - t_a} - (t_b - t_a)\mathbf{g} \cdot (\mathbf{x}_b + \mathbf{x}_a) - \frac{1}{12}(t_b - t_a)^3 \mathbf{g}^2 \right] \right\}. \end{aligned} \quad (2.617)$$

The potential (2.611) can be considered as a limit of a harmonic potential

$$V(\mathbf{x}) = V_0 + \frac{M}{2}\omega^2(\mathbf{x} - \mathbf{x}_0)^2 \quad (2.618)$$

for

$$\omega \rightarrow 0, \quad \mathbf{x}_0 = -\mathbf{g}/\omega^2 \rightarrow -\infty \approx \hat{\mathbf{g}}, \quad V_0 = -M\mathbf{x}_0^2/2 = -Mg^2/2\omega^4 \rightarrow -\infty, \quad (2.619)$$

keeping

$$\mathbf{g} = -M\omega^2\mathbf{x}_0, \quad (2.620)$$

and

$$v_0 = V_0 + \frac{M}{2}\omega^2\mathbf{x}_0^2 \quad (2.621)$$

fixed. If we perform this limit in the amplitude (2.177), we find of course (2.617).

The wave functions can be obtained most easily by performing this limiting procedure on the wave functions of the harmonic oscillator. In one dimension, we set $n = E/\omega$ and find that the spectral representation (2.294) goes over into

$$(x_b t_b | x_a t_a) = \int dE A_E(x_b) A_E^*(x_a) e^{-i(E-v_0)(t_b-t_a)/\hbar}, \quad (2.622)$$

with the wave functions

$$A_E(x) = \frac{1}{\sqrt{l\varepsilon}} \text{Ai}\left(\frac{x}{l} - \frac{E}{\varepsilon}\right). \quad (2.623)$$

Here $\varepsilon \equiv (\hbar^2 g^2 M/2)^{1/3}$ and $l \equiv (\hbar^2/2M^2 g)^{1/3} = \varepsilon/Mg$ are the natural units of energy and length, respectively, and $\text{Ai}(z)$ is the *Airy function* solving the differential equation

$$\text{Ai}''(z) = z\text{Ai}(z), \quad (2.624)$$

For positive z , the Airy function can be expressed in terms of modified Bessel functions $I_\nu(\xi)$ and $K_\nu(\xi)$:³⁴

$$\text{Ai}(z) = \frac{\sqrt{z}}{2} [I_{-1/3}(2z^{3/2}/3) - I_{1/3}(2z^{3/2}/3)] = \frac{1}{\pi} \sqrt{\frac{z}{3}} K_{1/3}(2z^{3/2}/3). \quad (2.625)$$

For large z , this falls off exponentially:

$$\text{Ai}(z) \rightarrow \frac{1}{2\sqrt{\pi}z^{1/4}} e^{-2z^{3/2}/3}, \quad z \rightarrow \infty. \quad (2.626)$$

For negative z , an analytic continuation³⁵

$$\begin{aligned} I_\nu(\xi) &= e^{-\pi\nu i/2} J(e^{\pi i/2}\xi), & -\pi < \arg\xi \leq \pi/2, \\ I_\nu(\xi) &= e^{-\pi\nu i/2} J(e^{\pi i/2}\xi), & \pi/2 < \arg\xi \leq \pi, \end{aligned} \quad (2.627)$$

³⁴A compact description of the properties of Bessel functions is found in M. Abramowitz and I. Stegun, *op. cit.*, Chapter 10. The Airy function is expressed in Formulas 10.4.14.

³⁵I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formulas 8.406.

leads to

$$\text{Ai}(z) = \frac{1}{3}\sqrt{z} \left[J_{-1/3}(2(-z)^{3/2}/3) + J_{1/3}(2(-z)^{3/2}/3) \right], \quad (2.628)$$

where $J_{1/3}(\xi)$ are ordinary Bessel functions. For large arguments, these oscillate like

$$J_\nu(\xi) \rightarrow \sqrt{\frac{2}{\pi\xi}} \cos(\xi - \pi\nu/2 - \pi/4) + \mathcal{O}(\xi^{-1}), \quad (2.629)$$

from which we obtain the oscillating part of the Airy function

$$\text{Ai}(z) \rightarrow \frac{1}{\sqrt{\pi}z^{1/4}} \sin \left[2(-z)^{3/2}/3 + \pi/4 \right], \quad z \rightarrow -\infty. \quad (2.630)$$

The Airy function has the simple Fourier representation

$$\text{Ai}(x) = \int_{-\infty}^{\infty} \frac{dk}{2\pi} e^{i(xk+k^3/3)}. \quad (2.631)$$

In fact, the momentum space wave functions of energy E are

$$\langle p|E\rangle = \sqrt{\frac{l}{\varepsilon}} e^{-i(pE-p^3/6M)l/\varepsilon\hbar} \quad (2.632)$$

fulfilling the orthogonality and completeness relations

$$\int \frac{dp}{2\pi\hbar} \langle E'|p\rangle \langle p|E\rangle = \delta(E' - E), \quad \int dE \langle p'|E\rangle \langle E|p\rangle = 2\pi\hbar\delta(p' - p). \quad (2.633)$$

The Fourier transform of (2.632) is equal to (2.623), due to (2.631).

2.18 Charged Particle in Magnetic Field

Having learned how to solve the path integral of the harmonic oscillator we are ready to study also a more involved harmonic system of physical importance: a charged particle in a magnetic field. This problem was first solved by L.D. Landau in 1930 in Schrödinger theory.³⁶

2.18.1 Action

The magnetic interaction of a particle of charge e is given by

$$\mathcal{A}_{\text{mag}} = \frac{e}{c} \int_{t_a}^{t_b} dt \dot{\mathbf{x}}(t) \cdot \mathbf{A}(\mathbf{x}(t)), \quad (2.634)$$

where $\mathbf{A}(\mathbf{x})$ is the vector potential of the magnetic field. The total action is

$$\mathcal{A}[\mathbf{x}] = \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{x}}^2(t) + \frac{e}{c} \dot{\mathbf{x}}(t) \cdot \mathbf{A}(\mathbf{x}(t)) \right]. \quad (2.635)$$

³⁶L.D. Landau and E.M. Lifshitz, *Quantum Mechanics*, Pergamon, London, 1965.

Suppose now that the particle moves in a homogeneous magnetic field \mathbf{B} pointing along the z -direction. Such a field can be described by a vector potential

$$\mathbf{A}(\mathbf{x}) = (0, Bx, 0). \quad (2.636)$$

But there are other possibilities. The magnetic field

$$\mathbf{B}(\mathbf{x}) = \nabla \times \mathbf{A}(\mathbf{x}) \quad (2.637)$$

as well as the magnetic interaction (2.634) are invariant under gauge transformations

$$\mathbf{A}(\mathbf{x}) \rightarrow \mathbf{A}(\mathbf{x}) + \nabla \Lambda(\mathbf{x}), \quad (2.638)$$

where $\Lambda(\mathbf{x})$ are arbitrary single-valued functions of \mathbf{x} . As such they satisfy the Schwarz integrability condition [compare (1.40)–(1.41)]

$$(\partial_i \partial_j - \partial_j \partial_i) \Lambda(\mathbf{x}) = 0. \quad (2.639)$$

For instance, the axially symmetric vector potential

$$\tilde{\mathbf{A}}(\mathbf{x}) = \frac{1}{2} \mathbf{B} \times \mathbf{x} \quad (2.640)$$

gives the same magnetic field; it differs from (2.636) by a gauge transformation

$$\tilde{\mathbf{A}}(\mathbf{x}) = \mathbf{A}(\mathbf{x}) + \nabla \Lambda(\mathbf{x}), \quad (2.641)$$

with the gauge function

$$\Lambda(\mathbf{x}) = -\frac{1}{2} B xy. \quad (2.642)$$

In the canonical form, the action reads

$$\mathcal{A}[\mathbf{p}, \mathbf{x}] = \int_{t_a}^{t_b} dt \left\{ \mathbf{p} \cdot \dot{\mathbf{x}} - \frac{1}{2M} \left[\mathbf{p} - \frac{e}{c} \mathbf{A}(\mathbf{x}) \right]^2 \right\}. \quad (2.643)$$

The magnetic interaction of a point particle is thus included in the path integral by the so-called *minimal substitution* of the momentum variable:

$$\mathbf{p} \rightarrow \mathbf{P} \equiv \mathbf{p} - \frac{e}{c} \mathbf{A}(\mathbf{x}). \quad (2.644)$$

For the vector potential (2.636), the action (2.643) becomes

$$\mathcal{A}[\mathbf{p}, \mathbf{x}] = \int_{t_a}^{t_b} dt [\mathbf{p} \cdot \dot{\mathbf{x}} - H(\mathbf{p}, \mathbf{x})], \quad (2.645)$$

with the Hamiltonian

$$H(\mathbf{p}, \mathbf{x}) = \frac{\mathbf{p}^2}{2M} + \frac{1}{8} M \omega_L^2 \mathbf{x}^2 - \frac{1}{2} \omega_L l_z(\mathbf{p}, \mathbf{x}), \quad (2.646)$$

where $\mathbf{x} = (x, y)$ and $\mathbf{p} = (p_x, p_y)$ and

$$l_z(\mathbf{p}, \mathbf{x}) = (\mathbf{x} \times \mathbf{p})_z = xp_y - yp_x \quad (2.647)$$

is the z -component of the orbital angular momentum. In a Schrödinger equation, the last term in $H(\mathbf{p}, \mathbf{x})$ is diagonal on states with a given angular momentum around the z -axis. We have introduced the field-dependent frequency

$$\omega_L = \frac{e}{Mc}B, \quad (2.648)$$

called *Landau frequency* or *cyclotron frequency*. This can also be written in terms of the *Bohr magneton*

$$\mu_B \equiv \frac{\hbar e}{Mc}, \quad (2.649)$$

as

$$\omega_L = \mu_B B / \hbar. \quad (2.650)$$

The first two terms in (2.646) describe a harmonic oscillator in the xy -plane with a field-dependent *magnetic frequency*

$$\omega_B \equiv \frac{\omega_L}{2}. \quad (2.651)$$

Note that in the gauge (2.636), the Hamiltonian would have the rotationally noninvariant form

$$H(\mathbf{p}, \mathbf{x}) = \frac{\mathbf{p}^2}{2M} + \frac{1}{2}M\omega_L^2 x^2 - \omega_L xp_y \quad (2.652)$$

rather than (2.646), implying oscillations of frequency ω_L in the x -direction and a free motion in the y -direction.

The time-sliced form of the canonical action (2.643) reads

$$\mathcal{A}_e^N = \sum_{n=1}^{N+1} \left\{ \mathbf{p}_n(\mathbf{x}_n - \mathbf{x}_{n-1}) - \frac{1}{2M} [p_{x_n}^2 + (p_{y_n} - Bx_n)^2 + p_{z_n}^2] \right\}, \quad (2.653)$$

and the associated time-evolution amplitude for the particle to run from \mathbf{x}_a to \mathbf{x}_b is given by

$$\langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = \prod_{n=1}^N \left[\int d^3 x_n \right] \prod_{n=1}^{N+1} \left[\int \frac{d^3 p_n}{(2\pi\hbar)^3} \right] \exp \left(\frac{i}{\hbar} \mathcal{A}_e^N \right), \quad (2.654)$$

with the time-sliced action

$$\mathcal{A}^N = \sum_{n=1}^{N+1} \left\{ \mathbf{p}_n(\mathbf{x}_n - \mathbf{x}_{n-1}) - \frac{1}{2M} [p_{x_n}^2 + (p_{y_n} - Bx_n)^2 + p_{z_n}^2] \right\}. \quad (2.655)$$

2.18.2 Gauge Properties

Note that the time evolution amplitude is not gauge-invariant. If we use the vector potential in some other gauge

$$\mathbf{A}'(\mathbf{x}) = \mathbf{A}(\mathbf{x}) + \nabla \Lambda(\mathbf{x}), \quad (2.656)$$

the action changes by a surface term

$$\Delta \mathcal{A} = \frac{e}{c} \int_{t_a}^{t_b} dt \dot{\mathbf{x}} \cdot \nabla \Lambda(\mathbf{x}) = \frac{e}{c} [\Lambda(\mathbf{x}_b) - \Lambda(\mathbf{x}_a)]. \quad (2.657)$$

The amplitude is therefore multiplied by a phase factor on both ends

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a)_A \rightarrow (\mathbf{x}_b t_b | \mathbf{x}_a t_a)_{A'} = e^{ie\Lambda(\mathbf{x}_b)/c\hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a)_A e^{-ie\Lambda(\mathbf{x}_a)/c\hbar}. \quad (2.658)$$

For the observable particle distribution $(\mathbf{x} t_b | \mathbf{x} t_a)$, the phase factors are obviously irrelevant. But all other observables of the system must also be independent of the phases $\Lambda(\mathbf{x})$ which is assured if they correspond to gauge-invariant operators.

2.18.3 Time-Sliced Path Integration

Since the action \mathcal{A}^N contains the variables y_n and z_n only in the first term $\sum_{n=1}^{N+1} i\mathbf{p}_n \mathbf{x}_n$, we can perform the y_n, z_n integrations and find a product of N Δ -functions in the y - and z -components of the momenta \mathbf{p}_n . If the projections of \mathbf{p} to the yz -plane are denoted by \mathbf{p}' , the product is

$$(2\pi\hbar)^2 \delta^{(2)}(\mathbf{p}'_{N+1} - \mathbf{p}'_N) \cdots (2\pi\hbar)^2 \delta^{(2)}(\mathbf{p}'_2 - \mathbf{p}'_1). \quad (2.659)$$

These allow performing all p_{y_n}, p_{z_n} -integrals, except for one overall p_y, p_z . The path integral reduces therefore to

$$\begin{aligned} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) &= \int_{-\infty}^{\infty} \frac{dp_y dp_z}{(2\pi\hbar)^2} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int \frac{dp_{x_n}}{2\pi\hbar} \right] \\ &\times \exp \left\{ \frac{i}{\hbar} \left[p_y (y_b - y_a) + p_z (z_b - z_a) - (t_b - t_a) \frac{p_z^2}{2M} \right] \right\} \exp \left(\frac{i}{\hbar} \mathcal{A}_x^N \right), \end{aligned} \quad (2.660)$$

where \mathcal{A}_x^N is the time-sliced action involving only a one-dimensional path integral over the x -component of the path, $x(t)$, with the sliced action

$$\mathcal{A}_x^N = \sum_{n=1}^{N+1} \left[p_{x_n} (x_n - x_{n-1}) - \frac{p_{x_n}^2}{2M} - \frac{1}{2M} \left(p_y - \frac{e}{c} B x_n \right)^2 \right]. \quad (2.661)$$

This is the action of a one-dimensional harmonic oscillator with field-dependent frequency ω_B whose center of oscillation depends on p_y and lies at

$$x_0 = p_y / M\omega_L. \quad (2.662)$$

The path integral over $x(t)$ is harmonic and known from (2.175):

$$(x_b t_b | x_a t_a)_{x_0} = \sqrt{\frac{M\omega_L}{2\pi i\hbar \sin \omega_L(t_b - t_a)}} \times \exp\left(\frac{i}{\hbar} \frac{M\omega_L}{2 \sin \omega_L(t_b - t_a)} \left\{ [(x_b - x_0)^2 + (x_a - x_0)^2] \cos \omega_L(t_b - t_a) - 2(x_b - x_0)(x_a - x_0) \right\}\right). \quad (2.663)$$

Doing the p_z -integral in (2.660), we arrive at the formula

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \frac{1}{\sqrt{2\pi i\hbar(t_b - t_a)/M}} e^{i\frac{M}{2\hbar} \frac{(z_b - z_a)^2}{t_b - t_a}} (\mathbf{x}_b^\perp t_b | \mathbf{x}_a^\perp t_a), \quad (2.664)$$

with the amplitude orthogonal to the magnetic field

$$(\mathbf{x}_b^\perp t_b | \mathbf{x}_a^\perp t_a) \equiv \frac{M\omega_L}{2\pi\hbar} \int_{-\infty}^{\infty} dx_0 e^{iM\omega_L x_0(y_b - y_a)/\hbar} (x_b t_b | x_a t_a)_{x_0}. \quad (2.665)$$

After a quadratic completion in x_0 , the total exponent in (2.665) reads

$$\begin{aligned} & \frac{iM\omega_L}{2\hbar} \left[-(x_b^2 + x_a^2) \tan[\omega_L(t_b - t_a)/2] + (x_b - x_a)^2 \frac{1}{\sin \omega_L(t_b - t_a)} \right] \\ & - i \frac{M\omega_L}{\hbar} \tan[\omega_L(t_b - t_a)/2] \left(x_0 - \frac{x_b + x_a}{2} - \frac{y_b - y_a}{2 \tan[\omega_L(t_b - t_a)/2]} \right)^2 \\ & + i \frac{M\omega_L}{2\hbar} \left[\frac{(x_b + x_a)^2}{2} \tan[\omega_L(t_b - t_a)/2] + \frac{(y_b - y_a)^2}{2 \tan[\omega_L(t_b - t_a)/2]} \right] \\ & + i \frac{M\omega_L}{2\hbar} (x_b + x_a)(y_b - y_a). \end{aligned} \quad (2.666)$$

The integration $M\omega_L \int_{-\infty}^{\infty} dx_0 / 2\pi\hbar$ removes the second term and results in a factor

$$\frac{M\omega_L}{2\pi\hbar} \sqrt{\frac{\pi\hbar}{iM\omega_L \tan[\omega_L(t_b - t_a)/2]}}. \quad (2.667)$$

By rearranging the remaining terms, we arrive at the amplitude

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \sqrt{\frac{M}{2\pi i\hbar(t_b - t_a)}} \frac{\omega_L(t_b - t_a)/2}{\sin[\omega_L(t_b - t_a)/2]} \exp\left[\frac{i}{\hbar} (\mathcal{A}_{\text{cl}} + \mathcal{A}_{\text{sf}})\right], \quad (2.668)$$

with an action

$$\mathcal{A}_{\text{cl}} = \frac{M}{2} \left\{ \frac{(z_b - z_a)^2}{t_b - t_a} + \frac{\omega_L}{2} \cot[\omega_L(t_b - t_a)/2] [(x_b - x_a)^2 + (y_b - y_a)^2] + \omega_L(x_a y_b - x_b y_a) \right\}, \quad (2.669)$$

and the surface term

$$\mathcal{A}_{\text{sf}} = \frac{M\omega_L}{2} (x_b y_b - x_a y_a) = \frac{e}{2c} B xy \Big|_a^b. \quad (2.670)$$

2.18.4 Classical Action

Since the action is harmonic, the amplitude is again a product of a phase $e^{i\mathcal{A}_{\text{cl}}}$ and a fluctuation factor. A comparison with (2.641) and (2.658) shows that the surface term would be absent if the amplitude $(\mathbf{x}_b t_b | \mathbf{x}_a t_a)_{\bar{A}}$ were calculated with the vector potential in the axially symmetric gauge (2.640). Thus \mathcal{A}_{cl} must be equal to the classical action in this gauge. Indeed, the orthogonal part can be rewritten as

$$\mathcal{A}_{\text{cl}}^{\perp} = \int_{t_a}^{t_b} dt \left\{ \frac{M}{2} \frac{d}{dt} (x\dot{x} + y\dot{y}) + \frac{M}{2} [x(-\ddot{x} + \omega_L \dot{y}) + y(-\ddot{y} - \omega_L \dot{x})] \right\}. \quad (2.671)$$

The equations of motion are

$$\ddot{x} = \omega_L \dot{y}, \quad \ddot{y} = -\omega_L \dot{x}, \quad (2.672)$$

reducing the action of a classical orbit to

$$\mathcal{A}_{\text{cl}}^{\perp} = \frac{M}{2} (x\dot{x} + y\dot{y}) \Big|_{t_a}^{t_b} = \frac{M}{2} ([x_b \dot{x}_b - x_a \dot{x}_a] + [y_b \dot{y}_b - y_a \dot{y}_a]). \quad (2.673)$$

The orbits are easily determined. By inserting the two equations in (2.672) into each other we see that \dot{x} and \dot{y} perform independent oscillations:

$$\dot{\ddot{x}} + \omega_L^2 \dot{x} = 0, \quad \dot{\ddot{y}} + \omega_L^2 \dot{y} = 0. \quad (2.674)$$

The general solution of these equations is

$$x = \frac{1}{\sin \omega_L (t_b - t_a)} [(x_b - x_0) \sin \omega_L (t - t_a) - (x_a - x_0) \sin \omega_L (t - t_b)] + x_0, \quad (2.675)$$

$$y = \frac{1}{\sin \omega_L (t_b - t_a)} [(y_b - y_0) \sin \omega_L (t - t_a) - (y_a - y_0) \sin \omega_L (t - t_b)] + y_0, \quad (2.676)$$

where we have incorporated the boundary condition $x(t_{a,b}) = x_{a,b}$, $y(t_{a,b}) = y_{a,b}$. The constants x_0, y_0 are fixed by satisfying (2.672). This gives

$$x_0 = \frac{1}{2} \left[(x_b + x_a) + (y_b - y_a) \cot \frac{\omega_L}{2} (t_b - t_a) \right], \quad (2.677)$$

$$y_0 = \frac{1}{2} \left[(y_b + y_a) - (x_b - x_a) \cot \frac{\omega_L}{2} (t_b - t_a) \right]. \quad (2.678)$$

Now we calculate

$$x_b \dot{x}_b = \frac{\omega_L}{\sin \omega_L (t_b - t_a)} x_b [(x_0 - x_a) + (x_b - x_0) \cos \omega_L (t_b - t_a)], \quad (2.679)$$

$$x_a \dot{x}_a = \frac{\omega_L}{\sin \omega_L (t_b - t_a)} x_a [(x_0 - x_a) \cos \omega_L (t_b - t_a) + (x_b - x_0)], \quad (2.680)$$

and hence

$$\begin{aligned} x_b \dot{x}_b - x_a \dot{x}_a &= \omega_L x_0 (x_b + x_a) \tan \frac{\omega_L}{2} (t_b - t_a) \\ &\quad + \frac{\omega_L}{\sin \omega_L (t_b - t_a)} [(x_b^2 + x_a^2) \cos \omega_L (t_b - t_a) - 2x_b x_a] \\ &= \frac{\omega_L}{2} \left[(x_b - x_a)^2 \cot \frac{\omega_L}{2} (t_b - t_a) + (x_b + x_a)(y_b - y_a) \right]. \end{aligned} \quad (2.681)$$

Similarly we find

$$\begin{aligned}
y_b \dot{y}_b - y_a \dot{y}_a &= \omega_L y_0 (y_b + y_a) \tan \frac{\omega_L}{2} (t_b - t_a) \\
&\quad + \frac{\omega_L}{\sin \omega_L (t_b - t_a)} [(y_b^2 + y_a^2) \cos \omega_L (t_b - t_a) - 2y_b y_a] \\
&= \frac{\omega_L}{2} \left[(y_b - y_a)^2 \cot \frac{\omega_L}{2} (t_b - t_a) - (x_b - x_a)(y_b + y_a) \right]. \quad (2.682)
\end{aligned}$$

Inserted into (2.673), this yields the classical action for the orthogonal motion

$$\mathcal{A}_{\text{cl}}^\perp = \frac{M}{2} \left\{ \frac{\omega_L}{2} \cot[\omega_L (t_b - t_a)/2] [(x_b - x_a)^2 + (y_b - y_a)^2] + \omega_L (x_a y_b - x_b y_a) \right\}, \quad (2.683)$$

which is indeed the orthogonal part of the action (2.669).

2.18.5 Translational Invariance

It is interesting to see how the amplitude ensures the translational invariance of all physical observables. The first term in the classical action is trivially invariant. The last term reads

$$\Delta \mathcal{A} = \frac{M\omega_L}{2} (x_a y_b - x_b y_a). \quad (2.684)$$

Under a translation by a distance \mathbf{d} ,

$$\mathbf{x} \rightarrow \mathbf{x} + \mathbf{d}, \quad (2.685)$$

this term changes by

$$\frac{M\omega_L}{2} [d_x (y_b - y_a) + d_y (x_a - x_b)] = \frac{M\omega_L}{2} [(\mathbf{d} \times \mathbf{x})_b - (\mathbf{d} \times \mathbf{x})_a]_z \quad (2.686)$$

causing the amplitude to change by a pure gauge transformation as

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) \rightarrow e^{ie\Lambda(\mathbf{x}_b)/c\hbar} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) e^{-ie\Lambda(\mathbf{x}_a)/c\hbar}, \quad (2.687)$$

with the phase

$$\Lambda(\mathbf{x}) = -\frac{M\omega_L \hbar c}{2e} [\mathbf{d} \times \mathbf{x}]_z. \quad (2.688)$$

Since observables involve only gauge-invariant quantities, such transformations are irrelevant.

This will be done in 2.23.3.

2.19 Charged Particle in Magnetic Field plus Harmonic Potential

For application in Chapter 5 we generalize the above magnetic system by adding a harmonic oscillator potential, thus leaving the path integral solvable. For simplicity, we consider only the orthogonal part of the resulting system with respect to the magnetic field. Omitting orthogonality symbols, the Hamiltonian is the same as in (2.646). Without much more work we may solve the path integral of a more general system in which the harmonic potential in (2.646) has a different frequency $\omega \neq \omega_L$, and thus a Hamiltonian

$$H(\mathbf{p}, \mathbf{x}) = \frac{\mathbf{p}^2}{2M} + \frac{1}{2}M\omega^2\mathbf{x}^2 - \omega_B l_z(\mathbf{p}, \mathbf{x}). \quad (2.689)$$

The associated Euclidean action

$$\mathcal{A}_e[\mathbf{p}, \mathbf{x}] = \int_{\tau_a}^{\tau_b} d\tau [-i\mathbf{p} \cdot \dot{\mathbf{x}} + H(\mathbf{p}, \mathbf{x})] \quad (2.690)$$

has the Lagrangian form

$$\mathcal{A}_e[\mathbf{x}] = \int_0^{\hbar\beta} d\tau \left\{ \frac{M}{2}\dot{\mathbf{x}}^2(\tau) + \frac{1}{2}M(\omega^2 - \omega_B^2)\mathbf{x}^2(\tau) - iM\omega_B[\mathbf{x}(\tau) \times \dot{\mathbf{x}}(\tau)]_z \right\}. \quad (2.691)$$

At this point we observe that the system is stable only for $\omega \geq \omega_B$. The action (2.691) can be written in matrix notation as

$$\mathcal{A}_{\text{cl}} = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \frac{d}{d\tau} (\mathbf{x}\dot{\mathbf{x}}) + \frac{M}{2} \mathbf{x}^T \mathbf{D}_{\omega^2, B} \mathbf{x} \right], \quad (2.692)$$

where $\mathbf{D}_{\omega^2, B}$ is the 2×2 -matrix

$$\mathbf{D}_{\omega^2, B}(\tau, \tau') \equiv \begin{pmatrix} -\partial_\tau^2 + \omega^2 - \omega_B^2 & -2i\omega_B\partial_\tau \\ 2i\omega_B\partial_\tau & -\partial_\tau^2 + \omega^2 - \omega_B^2 \end{pmatrix} \delta(\tau - \tau'). \quad (2.693)$$

Since the path integral is Gaussian, we can immediately calculate the partition function

$$Z = \frac{1}{(2\pi\hbar/M)^2} \det \mathbf{D}_{\omega^2, B}^{-1/2}. \quad (2.694)$$

By expanding $\mathbf{D}_{\omega^2, B}(\tau, \tau')$ in a Fourier series

$$\mathbf{D}_{\omega^2, B}(\tau, \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \tilde{\mathbf{D}}_{\omega^2, B}(\omega_m) e^{-i\omega_m(\tau-\tau')}, \quad (2.695)$$

we find the Fourier components

$$\tilde{\mathbf{D}}_{\omega^2, B}(\omega_m) = \begin{pmatrix} \omega_m^2 + \omega^2 - \omega_B^2 & -2\omega_B\omega_m \\ 2\omega_B\omega_m & \omega_m^2 + \omega^2 - \omega_B^2 \end{pmatrix}, \quad (2.696)$$

with the determinants

$$\det \tilde{\mathbf{D}}_{\omega^2, B}(\omega_m) = (\omega_m^2 + \omega^2 - \omega_B^2)^2 + 4\omega_B^2\omega_m^2. \quad (2.697)$$

These can be factorized as

$$\det \tilde{\mathbf{D}}_{\omega^2, B}(\omega_m) = (\omega_m^2 + \omega_+^2)(\omega_m^2 + \omega_-^2), \quad (2.698)$$

with

$$\omega_{\pm} \equiv \omega \pm \omega_B. \quad (2.699)$$

The eigenvectors of $\tilde{\mathbf{D}}_{\omega^2, B}(\omega_m)$ are

$$\mathbf{e}_+ = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ i \end{pmatrix}, \quad \mathbf{e}_- = -\frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -i \end{pmatrix}, \quad (2.700)$$

with eigenvalues

$$d_{\pm} = \omega_m^2 + \omega^2 \pm 2i\omega_m\omega_B = (\omega_m + i\omega_{\pm})(\omega_m - i\omega_{\mp}). \quad (2.701)$$

Thus the right- and left-circular combinations $x_{\pm} = \pm(x \pm iy)/\sqrt{2}$ diagonalize the Lagrangian (2.692) to

$$\begin{aligned} \mathcal{A}_{\text{cl}} = & \int_0^{\hbar\beta} d\tau \left\{ \frac{M}{2} \frac{d}{d\tau} (x_+^* \dot{x}_+ + x_-^* \dot{x}_-) \right. \\ & \left. + \frac{M}{2} [x_+^* (-\partial_{\tau} - \omega_+) (-\partial_{\tau} + \omega_-) x_+ + x_-^* (-\partial_{\tau} - \omega_-) (-\partial_{\tau} + \omega_+) x_-] \right\}. \end{aligned} \quad (2.702)$$

Continued back to real times, the components $x_{\pm}(t)$ are seen to oscillate independently with the frequencies ω_{\pm} .

The factorization (2.698) makes (2.702) an action of two independent harmonic oscillators of frequencies ω_{\pm} . The associated partition function has therefore the product form

$$Z = \frac{1}{2 \sinh(\hbar\beta\omega_+/2)} \frac{1}{2 \sinh(\hbar\beta\omega_-/2)}. \quad (2.703)$$

For the original system of a charged particle in a magnetic field discussed in Section 2.18, the partition function is obtained by going to the limit $\omega \rightarrow \omega_B$ in the Hamiltonian (2.689). Then $\omega_- \rightarrow 0$ and the partition function (2.703) diverges, since the system becomes translationally invariant in space. From the mnemonic replacement rule (2.361) we see that in this limit we must replace the vanishing inverse frequency by an expression proportional to the volume of the system. The role of ω^2 in (2.361) is played here by the frequency in front of the \mathbf{x}^2 -term of the Lagrangian (2.691). Since there are two dimensions, we must replace

$$\frac{1}{\omega^2 - \omega_B^2} \xrightarrow{\omega \rightarrow \omega_B} \frac{1}{2\omega\omega_-} \xrightarrow{\omega_- \rightarrow 0} \frac{\beta}{2\pi/M} V_2, \quad (2.704)$$

and thus

$$Z \xrightarrow{\omega_- \rightarrow 0} \frac{1}{2 \sinh(\hbar\beta\omega)} \frac{V_2}{\lambda_{\omega}^2}, \quad (2.705)$$

where λ_{ω} is the quantum-mechanical length scale in Eqs. (2.303) and (2.359) of the harmonic oscillator.

2.20 Gauge Invariance and Alternative Path Integral Representation

The action (2.635) of a particle in an external ordinary potential $V(\mathbf{x}, t)$ and a vector potential $\mathbf{A}(\mathbf{x}, t)$ can be rewritten with the help of an arbitrary space- and time-dependent gauge function $\Lambda(\mathbf{x}, t)$ in the following form:

$$\begin{aligned} \mathcal{A}[\mathbf{x}] = \int_{t_a}^{t_b} dt \left\{ \frac{M}{2} \dot{\mathbf{x}}^2 + \frac{e}{c} \dot{\mathbf{x}}(t) [\mathbf{A}(\mathbf{x}, t) + \nabla \Lambda(\mathbf{x}, t)] - V(\mathbf{x}, t) + \frac{e}{c} \partial_t \Lambda(\mathbf{x}, t) \right\} \\ - \frac{e}{c} [\Lambda(\mathbf{x}_b, t_b) - \Lambda(\mathbf{x}_a, t_a)]. \end{aligned} \quad (2.706)$$

The $\Lambda(\mathbf{x}, t)$ -terms inside the integral are canceled by the last two surface terms making the action independent of $\Lambda(\mathbf{x}, t)$.

We may now choose a particular function $\Lambda(\mathbf{x}, t)$ equal to c/e -times the classical action $A(\mathbf{x}, t)$ which solves the Hamilton-Jacobi equation (1.65), i.e.,

$$\frac{1}{2M} \left[\nabla A(\mathbf{x}, t) - \frac{e}{c} \mathbf{A}(\mathbf{x}, t) \right]^2 + \partial_t A(\mathbf{x}, t) + V(\mathbf{x}, t) = 0. \quad (2.707)$$

Then we obtain the following alternative expression for the action:

$$\begin{aligned} \mathcal{A}[\mathbf{x}] = \int_{t_a}^{t_b} dt \frac{1}{2M} \left[M \dot{\mathbf{x}} - \nabla A(\mathbf{x}, t) + \frac{e}{c} \mathbf{A}(\mathbf{x}, t) \right]^2 \\ + A(\mathbf{x}_b, t_b) - A(\mathbf{x}_a, t_a). \end{aligned} \quad (2.708)$$

For two infinitesimally different solutions of the Hamilton-Jacobi equation, the difference between the associated action functions δA satisfies the differential equation

$$\mathbf{v} \cdot \nabla \delta A + \partial_t \delta A = 0, \quad (2.709)$$

where \mathbf{v} is the classical velocity field

$$\mathbf{v}(\mathbf{x}, t) \equiv (1/M) \left[\nabla A(\mathbf{x}, t) - \frac{e}{c} \mathbf{A}(\mathbf{x}, t) \right]. \quad (2.710)$$

The differential equation (2.709) expresses the fact that two solutions $A(\mathbf{x}, t)$ for which the particle energy and momenta at \mathbf{x} and t differ by δE and $\delta \mathbf{p}$, respectively, satisfy the kinematic relation $\delta E = \mathbf{p} \cdot \delta \mathbf{p} / M = \dot{\mathbf{x}}_{cl} \cdot \nabla \delta A$. This follows directly from $E = \mathbf{p}^2 / 2M$. The so-constrained variations δE and $\delta \mathbf{p}$ leave the action (2.708) invariant.

A sequence of changes δA of this type can be used to make the function $A(\mathbf{x}, t)$ coincide with the action $A(\mathbf{x}, t; \mathbf{x}_a, t_a)$ of paths which start out from \mathbf{x}_a, t_a and arrive at \mathbf{x}, t . In terms of this action function, the path integral representation of the time evolution amplitude takes the form

$$\begin{aligned} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = e^{iA(\mathbf{x}_b, t_b; \mathbf{x}_a, t_a) / \hbar} \int_{\mathbf{x}(t_a) = \mathbf{x}_a}^{\mathbf{x}(t_b) = \mathbf{x}_b} \mathcal{D}\mathbf{x} \\ \times \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{1}{2M} \left[M \dot{\mathbf{x}} - \nabla A(\mathbf{x}, t; \mathbf{x}_a, t_a) + \frac{e}{c} \mathbf{A}(\mathbf{x}, t) \right]^2 \right\} \end{aligned} \quad (2.711)$$

or, using $\mathbf{v}(\mathbf{x}(t), t)$,

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = e^{iA(\mathbf{x}_b, t_b; \mathbf{x}_a, t_a) / \hbar} \int_{\mathbf{x}(t_a) = \mathbf{x}_a}^{\mathbf{x}(t_b) = \mathbf{x}_b} \mathcal{D}\mathbf{x} \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{\mathbf{x}} - \mathbf{v})^2 \right]. \quad (2.712)$$

The fluctuations are now controlled by the deviations of the instantaneous velocity $\dot{\mathbf{x}}(t)$ from local value of the classical velocity field $\mathbf{v}(\mathbf{x}, t)$. Since the path integral attempts to keep the deviations as small as possible, we call $\mathbf{v}(\mathbf{x}, t)$ the *desired velocity* of the particle at \mathbf{x} and t . Introducing momentum variables $\mathbf{p}(t)$, the amplitude may be written as a phase space path integral

$$\begin{aligned} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) &= e^{iA(\mathbf{x}_b, t_b; \mathbf{x}_a, t_a)/\hbar} \int_{\mathbf{x}(t_a)=\mathbf{x}_a}^{\mathbf{x}(t_b)=\mathbf{x}_b} \mathcal{D}'\mathbf{x} \int \frac{\mathcal{D}\mathbf{p}}{2\pi\hbar} \\ &\times \exp\left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left\{ \mathbf{p}(t) [\dot{\mathbf{x}}(t) - \mathbf{v}(\mathbf{x}(t), t)] - \frac{1}{2M} \mathbf{p}^2(t) \right\}\right), \end{aligned} \quad (2.713)$$

which will be used in Section 18.15 to give a stochastic interpretation of quantum processes.

2.21 Velocity Path Integral

There exists yet another form of writing the path integral in which the fluctuating velocities play a fundamental role and which will later be seen to be closely related to path integrals in the so-called stochastic calculus to be introduced in Sections 18.13 and 18.640. We observe that by rewriting the path integral as

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \int \mathcal{D}^3 x \delta\left(\mathbf{x}_b - \mathbf{x}_a - \int_{t_a}^{t_b} dt \dot{\mathbf{x}}(t)\right) \exp\left\{\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{x}}^2 - V(\mathbf{x})\right]\right\}, \quad (2.714)$$

the δ -function allows us to include the last variable \mathbf{x}_n in the integration measure of the time-sliced version of the path integral. Thus all time-sliced time derivatives $(\mathbf{x}_{n+1} - \mathbf{x}_n)/\epsilon$ for $n = 0$ to N are integrated over implying that they can be considered as independent fluctuating variables \mathbf{v}_n . In the potential, the dependence on the velocities can be made explicit by inserting

$$\mathbf{x}(t) = \mathbf{x}_b - \int_t^{t_b} dt \mathbf{v}(t), \quad (2.715)$$

$$\mathbf{x}(t) = \mathbf{x}_a + \int_{t_a}^t dt \mathbf{v}(t), \quad (2.716)$$

$$\mathbf{x}(t) = \mathbf{X} + \frac{1}{2} \int_{t_a}^{t_b} dt' \mathbf{v}(t') \epsilon(t' - t), \quad (2.717)$$

where

$$\mathbf{X} \equiv \frac{\mathbf{x}_b + \mathbf{x}_a}{2} \quad (2.718)$$

is the average position of the endpoints and $\epsilon(t - t')$ is the antisymmetric combination of Heaviside functions introduced in Eq. (1.315).

In the first replacement, we obtain the *velocity path integral*

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \int \mathcal{D}^3 v \delta\left(\mathbf{x}_b - \mathbf{x}_a - \int_{t_a}^{t_b} dt \mathbf{v}(t)\right) \exp\left\{\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \mathbf{v}^2 - V\left(\mathbf{x}_b - \int_t^{t_b} dt' \mathbf{v}(t')\right)\right]\right\}. \quad (2.719)$$

The measure of integration is normalized to make

$$\int \mathcal{D}^3 v \exp\left\{\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \mathbf{v}^2\right]\right\} = 1. \quad (2.720)$$

The correctness of this normalization can be verified by evaluating (2.719) for a free particle. Inserting the Fourier representation for the δ -function

$$\delta\left(\mathbf{x}_b - \mathbf{x}_a - \int_{t_a}^{t_b} dt \mathbf{v}(t)\right) = \int \frac{d^3 p}{(2\pi i)^3} \exp\left[\frac{i}{\hbar} \mathbf{p} \left(\mathbf{x}_b - \mathbf{x}_a - \int_{t_a}^{t_b} dt \mathbf{v}(t)\right)\right], \quad (2.721)$$

we can complete the square in the exponent and integrate out the \mathbf{v} -fluctuations using (2.720) to obtain

$$\langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = \int \frac{d^3 p}{(2\pi i)^3} \exp \left\{ \frac{i}{\hbar} \left[\mathbf{p} \cdot (\mathbf{x}_b - \mathbf{x}_a) - \frac{\mathbf{p}^2}{2M} (t_b - t_a) \right] \right\}. \quad (2.722)$$

This is precisely the spectral representation (1.333) of the free-particle time evolution amplitude (1.335) [see also Eq. (2.53)].

A more symmetric velocity path integral is obtained by choosing the third replacement (2.717). This leads to the expression

$$\begin{aligned} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle &= \int \mathcal{D}^3 v \delta \left(\Delta \mathbf{x} - \int_{t_a}^{t_b} dt \mathbf{v}(t) \right) \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \mathbf{v}^2 \right\} \\ &\times \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t_b} dt V \left(\mathbf{X} + \frac{1}{2} \int_{t_a}^{t_b} dt' \mathbf{v}(t') \epsilon(t' - t) \right) \right\}. \end{aligned} \quad (2.723)$$

The velocity representations are particularly useful if we want to know integrated amplitudes such as

$$\begin{aligned} \int d^3 x_a \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle &= \int \mathcal{D}^3 v \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \mathbf{v}^2 \right\} \\ &\times \exp \left\{ -\frac{i}{\hbar} \int_{t_a}^{t_b} dt V \left(\mathbf{x}_b - \frac{1}{2} \int_t^{t_b} dt' \mathbf{v}(t') \right) \right\}, \end{aligned} \quad (2.724)$$

which will be of use in the next section.

2.22 Path Integral Representation of the Scattering Matrix

In Section 1.16 we have seen that the description of scattering processes requires several nontrivial limiting procedures on the time evolution amplitude. Let us see what these procedures yield when applied to the path integral representation of this amplitude.

2.22.1 General Development

Formula (1.474) for the scattering matrix expressed in terms of the time evolution operator in momentum space has the following path integral representation:

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv \lim_{t_b - t_a \rightarrow \infty} e^{i(E_b t_b - E_a t_a)/\hbar} \int d^3 x_b \int d^3 x_a e^{-i(\mathbf{p}_b \mathbf{x}_b - \mathbf{p}_a \mathbf{x}_a)/\hbar} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle. \quad (2.725)$$

Introducing the momentum transfer $\mathbf{q} \equiv (\mathbf{p}_b - \mathbf{p}_a)$, we rewrite $e^{-i(\mathbf{p}_b \mathbf{x}_b - \mathbf{p}_a \mathbf{x}_a)/\hbar}$ as $e^{-i\mathbf{q} \mathbf{x}_b/\hbar} e^{-i\mathbf{p}_a (\mathbf{x}_b - \mathbf{x}_a)/\hbar}$, and observe that the amplitude including the exponential prefactor $e^{-i\mathbf{p}_a (\mathbf{x}_b - \mathbf{x}_a)/\hbar}$ has the path integral representation:

$$e^{-i\mathbf{p}_a (\mathbf{x}_b - \mathbf{x}_a)/\hbar} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = \int \mathcal{D}^3 x \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{x}}^2 - \mathbf{p}_a \dot{\mathbf{x}} - V(\mathbf{x}) \right] \right\}. \quad (2.726)$$

The linear term in $\dot{\mathbf{x}}$ is eliminated by shifting the path from $\mathbf{x}(t)$ to

$$\mathbf{y}(t) = \mathbf{x}(t) - \frac{\mathbf{p}_a}{M} t \quad (2.727)$$

leading to

$$e^{-i\mathbf{p}_a (\mathbf{x}_b - \mathbf{x}_a)/\hbar} \langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = e^{-i\mathbf{p}_a^2 (t_b - t_a)/2M\hbar} \int \mathcal{D}^3 y \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{y}}^2 - V \left(\mathbf{y} + \frac{\mathbf{p}_a}{M} t \right) \right] \right\}. \quad (2.728)$$

Inserting everything into (2.725) we obtain

$$\begin{aligned} \langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle &\equiv \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2 t_b / 2M\hbar} \int d^3 y_b e^{-i\mathbf{q}\mathbf{y}_b / \hbar} \int d^3 y_a \\ &\times \int \mathcal{D}^3 y \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{y}}^2 - V \left(\mathbf{y} + \frac{\mathbf{p}_a}{M} t \right) \right] \right\}. \end{aligned} \quad (2.729)$$

In the absence of an interaction, the path integral over $\mathbf{y}(t)$ gives simply

$$\int d^3 y_a \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{y}_b - \mathbf{y}_a)^2}{t_b - t_a} \right] = 1, \quad (2.730)$$

and the integral over \mathbf{y}_a yields

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle |_{V=0} = \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2 (t_b - t_a) / 8M\hbar} (2\pi\hbar)^3 \delta^{(3)}(\mathbf{q}) = (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p}_b - \mathbf{p}_a), \quad (2.731)$$

which is the contribution from the unscattered beam to the scattering matrix in Eq. (1.477).

The first-order contribution from the interaction reads, after a Fourier decomposition of the potential,

$$\begin{aligned} \langle \mathbf{p}_b | \hat{S}_1 | \mathbf{p}_a \rangle &= -\frac{i}{\hbar} \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2 t_b / 2M\hbar} \int d^3 y_b e^{-i\mathbf{q}\mathbf{y}_b / \hbar} \int \frac{d^3 Q}{(2\pi\hbar)^3} V(\mathbf{Q}) \int d^3 y_a \\ &\times \int_{t_a}^{t_b} dt' \exp \left(\frac{i}{\hbar} \frac{\mathbf{p}_a \mathbf{Q}}{M} t' \right) \int \mathcal{D}^3 y \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{\mathbf{y}}^2 + \delta(t' - t) \mathbf{Q} \mathbf{y} \right] \right\}. \end{aligned} \quad (2.732)$$

The harmonic path integral was solved in one dimension for an arbitrary source $j(t)$ in Eq. (3.168). For $\omega = 0$ and the particular source $j(t) = \delta(t' - t)Q$ the result reads, in three dimensions,

$$\begin{aligned} &\frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M^3}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\mathbf{y}_b - \mathbf{y}_a)^2}{t_b - t_a} \right] \\ &\times \exp \left(\frac{i}{\hbar} \frac{1}{t_b - t_a} \left\{ [\mathbf{y}_b(t' - t_a) + \mathbf{y}_a(t_b - t')] \mathbf{Q} - \frac{1}{2M} (t_b - t')(t' - t_a) \mathbf{Q}^2 \right\} \right). \end{aligned} \quad (2.733)$$

Performing here the integral over \mathbf{y}_a yields

$$\exp \left\{ \frac{i}{\hbar} \mathbf{Q} \mathbf{y}_b \right\} \exp \left\{ -\frac{i}{\hbar} \frac{1}{2M} (t_b - t') \mathbf{Q}^2 \right\}. \quad (2.734)$$

The integral over \mathbf{y}_b in (2.732) leads now to a δ -function $(2\pi\hbar)^3 \delta^{(3)}(\mathbf{Q} - \mathbf{q})$, such that the exponential prefactor in (2.732) is canceled by part of the second factor in (2.734).

In the limit $t_b - t_a \rightarrow \infty$, the integral over t' produces a δ -function $2\pi\hbar \delta(\mathbf{p}_b \mathbf{Q} / M + \mathbf{Q}^2 / 2M) = 2\pi\hbar \delta(E_b - E_a)$ which enforces the conservation of energy. Thus we find the well-known Born approximation

$$\langle \mathbf{p}_b | \hat{S}_1 | \mathbf{p}_a \rangle = -2\pi i \delta(E_b - E_a) V(\mathbf{q}). \quad (2.735)$$

In general, we subtract the unscattered particle term (2.731) from (2.729), to obtain a path integral representation for the T -matrix [for the definition recall (1.477)]:

$$\begin{aligned} 2\pi\hbar i \delta(E_b - E_a) \langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle &\equiv - \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2 t_b / 2M\hbar} \int d^3 y_b e^{-i\mathbf{q}\mathbf{y}_b / \hbar} \int d^3 y_a \\ &\times \int \mathcal{D}^3 y \exp \left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \dot{\mathbf{y}}^2 \right) \left\{ \exp \left[-\frac{i}{\hbar} \int_{t_a}^{t_b} dt V \left(\mathbf{y} + \frac{\mathbf{p}_a}{M} t \right) \right] - 1 \right\}. \end{aligned} \quad (2.736)$$

It is preferable to find a formula which does not contain the δ -function of energy conservation as a factor on the left-hand side. In order to remove this we observe that its origin lies in the time-translational invariance of the path integral in the limit $t_b - t_a \rightarrow \infty$. If we go over to a shifted time variable $t \rightarrow t + t_0$, and change simultaneously $\mathbf{y} \rightarrow \mathbf{y} - \mathbf{p}_a t_0/M$, then the path integral remains the same except for shifted initial and final times $t_b + t_0$ and $t_a + t_0$. In the limit $t_b - t_a \rightarrow \infty$, the integrals $\int_{t_a+t_0}^{t_b+t_0} dt$ can be replaced again by $\int_{t_a}^{t_b} dt$. The only place where a t_0 -dependence remains is in the prefactor $e^{-i\mathbf{q}\mathbf{y}_b/\hbar}$ which changes to $e^{-i\mathbf{q}\mathbf{y}_b/\hbar} e^{i\mathbf{q}\mathbf{p}_a t_0/M\hbar}$. Among all path fluctuations, there exists one degree of freedom which is equivalent to a temporal shift of the path. This is equivalent to an integral over t_0 which yields a δ -function $2\pi\hbar\delta(\mathbf{q}\mathbf{p}_a/M) = 2\pi\hbar\delta(E_b - E_a)$. We only must make sure to find the relation between this temporal shift and the corresponding measure in the path integral. This is obviously a shift of the path as a whole in the direction $\hat{\mathbf{p}}_a \equiv \mathbf{p}_a/|\mathbf{p}_a|$. The formal way of isolating this degree of freedom proceeds according to a method developed by Faddeev and Popov³⁷ by inserting into the path integral (2.729) the following integral representation of unity:

$$1 = \frac{|\mathbf{p}_a|}{M} \int_{-\infty}^{\infty} dt_0 \delta(\hat{\mathbf{p}}_a(\mathbf{y}_b + \mathbf{p}_a t_0/M)). \quad (2.737)$$

In the following, we shall drop the subscript a of the incoming beam, writing

$$\mathbf{p} \equiv \mathbf{p}_a, \quad p \equiv |\mathbf{p}_a| = |\mathbf{p}_b|. \quad (2.738)$$

After the above shift in the path integral, the δ -function in (2.737) becomes $\delta(\hat{\mathbf{p}}_a \mathbf{y}_b)$ inside the path integral, with no t_0 -dependence. The integral over t_0 can now be performed yielding the δ -function in the energy. Removing this from the equation we obtain the path integral representation of the T -matrix

$$\begin{aligned} \langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle &\equiv i \frac{p}{M} \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2(t_b - t_a)/8M\hbar} \int d^3 y_b \delta(\hat{\mathbf{p}}_a \mathbf{y}_b) e^{-i\mathbf{q}\mathbf{y}_b/\hbar} \int d^3 y_a \\ &\times \int \mathcal{D}^3 y \exp\left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \dot{\mathbf{y}}^2\right) \left\{ \exp\left[-\frac{i}{\hbar} \int_{t_a}^{t_b} dt V\left(\mathbf{y} + \frac{\mathbf{P}}{M} t\right)\right] - 1 \right\}. \end{aligned} \quad (2.739)$$

At this point it is convenient to go over to the velocity representation of the path integral (2.723). This enables us to perform trivially the integral over \mathbf{y}_b , and we obtain the \mathbf{y} version of (2.724). The δ -function enforces a vanishing longitudinal component of \mathbf{y}_b . The transverse component of \mathbf{y}_b will be denoted by \mathbf{b} :

$$\mathbf{b} \equiv \mathbf{y}_b - (\hat{\mathbf{p}}_a \mathbf{y}_b) \hat{\mathbf{p}}_a. \quad (2.740)$$

Hence we find the path integral representation

$$\begin{aligned} \langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle &\equiv i \frac{p}{M} \lim_{t_b - t_a \rightarrow \infty} e^{i\mathbf{q}^2 t_b / 2M\hbar} \int d^2 b e^{-i\mathbf{q}\mathbf{b}/\hbar} \\ &\times \int \mathcal{D}^3 v \exp\left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \mathbf{v}^2\right) \left[e^{i\chi_{\mathbf{b},\mathbf{p}}[\mathbf{v}]} - 1 \right], \end{aligned} \quad (2.741)$$

where the effect of the interaction is contained in the scattering phase

$$\chi_{\mathbf{b},\mathbf{p}}[\mathbf{v}] \equiv -\frac{1}{\hbar} \int_{t_a}^{t_b} dt V\left(\mathbf{b} + \frac{\mathbf{p}}{M} t - \int_t^{t_b} dt' \mathbf{v}(t')\right). \quad (2.742)$$

We can go back to a more conventional path integral by replacing the velocity paths $\mathbf{v}(t)$ by $\dot{\mathbf{y}}(t) = -\int_t^{t_b} \mathbf{v}(t')$. This vanishes at $t = t_b$. Equivalently, we can use paths $\mathbf{z}(t)$ with periodic boundary conditions and subtract from these $\mathbf{z}(t_b) = \mathbf{z}_b$.

From $\langle \mathbf{p}_b | \hat{T} | \mathbf{p}_a \rangle$ we obtain the scattering amplitude $f_{\mathbf{p}_b, \mathbf{p}_a}$, whose square gives the differential cross section, by multiplying it with a factor $-M/2\pi\hbar$ [see Eq. (1.497)].

³⁷L.D. Faddeev and V.N. Popov, Phys. Lett. B 25, 29 (1967).

Note that in the velocity representation, the evaluation of the harmonic path integral integrated over \mathbf{y}_a in (2.732) is much simpler than before where we needed the steps (2.733), (2.734). After the Fourier decomposition of $V(\mathbf{x})$ in (2.742), the relevant integral is

$$\int \mathcal{D}^3 v \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \mathbf{v}^2 - \Theta(t_b - t') \mathbf{Q} \mathbf{v} \right] \right\} = e^{-\frac{i}{2M\hbar} \int_{t_a}^{t_b} dt \Theta^2(t_b - t') \mathbf{Q}^2} = e^{-\frac{i}{2M\hbar} (t_b - t') \mathbf{Q}^2}. \quad (2.743)$$

The first factor in (2.734) comes directly from the argument \mathbf{Y} in the Fourier representation of the potential

$$V \left(\mathbf{y}_b + \frac{\mathbf{p}}{M} t - \int_t^{t_b} dt' \mathbf{v}(t') \right)$$

in the velocity representation of the S -matrix (2.729).

2.22.2 Improved Formulation

The prefactor $e^{i\mathbf{q}^2 t_b / 2M\hbar}$ in Formula (2.741) is an obstacle to taking a more explicit limit $t_b - t_a \rightarrow \infty$ on the right-hand side. To overcome this, we represent this factor by an auxiliary path integral³⁸ over some vector field $\mathbf{w}(t)$:

$$e^{i\mathbf{q}^2 t_b / 2M\hbar} = \int \mathcal{D}^3 w \exp \left[-\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} \mathbf{w}^2(t) \right] e^{i \int_{t_a}^{t_b} dt \Theta(t) \mathbf{w}(t) \mathbf{q} / \hbar}. \quad (2.744)$$

The last factor changes the exponential $e^{-i\mathbf{q}\mathbf{b}/\hbar}$ in (2.741) into $e^{-i\mathbf{q} \left[\mathbf{b} + \int_{t_a}^{t_b} dt \Theta(t) \mathbf{w}(t) \right] / \hbar}$. Since \mathbf{b} is a dummy variable of integration, we can equivalently replace $\mathbf{b} \rightarrow \mathbf{b}_{\mathbf{w}} \equiv \mathbf{b} - \int_{t_a}^{t_b} dt \Theta(t) \mathbf{w}(t)$ in the scattering phase $\chi_{\mathbf{b}, \mathbf{p}}[\mathbf{v}]$ and remain with

$$\begin{aligned} f_{\mathbf{p}_b \mathbf{p}_a} &= \lim_{t_b - t_a \rightarrow \infty} \frac{p}{2\pi i \hbar} \int d^2 b e^{-i\mathbf{q}\mathbf{b}/\hbar} \int \mathcal{D}^3 w \\ &\times \int \mathcal{D}^3 v \exp \left[\frac{i}{\hbar} \int_{-\infty}^{\infty} dt \frac{M}{2} (\mathbf{v}^2 - \mathbf{w}^2) \right] [\exp(i\chi_{\mathbf{b}_{\mathbf{w}}, \mathbf{p}}) - 1]. \end{aligned} \quad (2.745)$$

The scattering phase in this expression can be calculated from formula (2.742) with the integral taken over the entire t -axis:

$$\chi_{\mathbf{b}_{\mathbf{w}}, \mathbf{p}}[\mathbf{v}, \mathbf{w}] = -\frac{1}{\hbar} \int_{-\infty}^{\infty} dt V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t - \int_{t_a}^{t_b} dt' [\Theta(t' - t) \mathbf{v}(t') - \Theta(t') \mathbf{w}(t')] \right). \quad (2.746)$$

The fluctuations of $\mathbf{w}(t)$ are necessary to correct for the fact that the outgoing particle does not run, on the average, with the velocity $\mathbf{p}/M = \mathbf{p}_a/M$ but with velocity $\mathbf{p}_b/M = (\mathbf{p} + \mathbf{q})/M$.

We may also go back to a more conventional path integral by inserting $\mathbf{y}(t) = -\int_t^{t_b} \mathbf{v}(t)$ and setting similarly $\mathbf{z}(t) = -\int_t^{t_b} \mathbf{w}(t)$. Then we obtain the alternative representation

$$\begin{aligned} f_{\mathbf{p}_b \mathbf{p}_a} &= \lim_{t_b - t_a \rightarrow \infty} \frac{p}{2\pi i \hbar} \int d^2 b e^{-i\mathbf{q}\mathbf{b}/\hbar} \int d^3 y_a \int d^3 z_a \\ &\times \int \mathcal{D}^3 y \int \mathcal{D}^3 z \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{\mathbf{y}}^2 - \dot{\mathbf{z}}^2) \right] [e^{i\chi_{\mathbf{b}_{\mathbf{z}}, \mathbf{p}}[\mathbf{y}]} - 1], \end{aligned} \quad (2.747)$$

³⁸See R. Rosenfelder, notes of a lecture held at the ETH Zürich in 1979: *Pfadintegrale in der Quantenphysik*, 126 p., PSI Report 97-12, ISSN 1019-0643, and Lecture held at the 7th Int. Conf. on Path Integrals in Antwerpen, *Path Integrals from Quarks to Galaxies*, 2002; Phys. Rev. A **79**, 012701 (2009).

with

$$\chi_{\mathbf{b},\mathbf{p}}[\mathbf{y}] \equiv -\frac{1}{\hbar} \int_{t_a}^{t_b} dt V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t + \mathbf{y}(t) - \mathbf{z}(0) \right), \quad (2.748)$$

where the path integrals run over all paths with $\mathbf{y}_b = 0$ and $\mathbf{z}_b = 0$. In Section 3.26 this path integral will be evaluated perturbatively.

2.22.3 Eikonal Approximation to the Scattering Amplitude

To lowest approximation, we neglect the fluctuating variables $\mathbf{y}(t)$ and $\mathbf{z}(t)$ in (2.748). Since the integral

$$\int d^3 y_a \int d^3 z_a \int \mathcal{D}^3 y \int \mathcal{D}^3 z \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{\mathbf{y}}^2 - \dot{\mathbf{z}}^2) \right] \quad (2.749)$$

in (2.747) has unit normalization [recall the calculation of (2.734)], we obtain directly the eikonal approximation to the scattering amplitude

$$f_{\mathbf{p}_b \mathbf{p}_a}^{\text{ei}} \equiv \frac{p}{2\pi i \hbar} \int d^2 b e^{-i\mathbf{q}\mathbf{b}/\hbar} [\exp(i\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}}) - 1], \quad (2.750)$$

with

$$\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}} \equiv -\frac{1}{\hbar} \int_{-\infty}^{\infty} dt V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t \right). \quad (2.751)$$

The time integration can be converted into a line integration along the direction of the incoming particles by introducing a variable $z \equiv pt/M$. Then we can write

$$\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}} \equiv -\frac{M}{p} \frac{1}{\hbar} \int_{-\infty}^{\infty} dz V(\mathbf{b} + \hat{\mathbf{p}}z). \quad (2.752)$$

If $V(\mathbf{x})$ is rotationally symmetric, it depends only on $r \equiv |\mathbf{x}|$. Then we shall write the potential as $V(r)$ and calculate (2.752) as the integral

$$\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}} \equiv -\frac{M}{p} \frac{1}{\hbar} \int_{-\infty}^{\infty} dz V \left(\sqrt{b^2 + z^2} \right). \quad (2.753)$$

Inserting this into (2.750), we can perform the integral over all angles between \mathbf{q} and \mathbf{b} using the formula

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} d\theta \exp \left(\frac{i}{\hbar} qb \cos \theta \right) = J_0(qb), \quad (2.754)$$

where $J_0(\xi)$ is the Bessel function, and find

$$f_{\mathbf{p}_b \mathbf{p}_a}^{\text{ei}} = \frac{p}{i\hbar} \int db b J_0(qb) [\exp(i\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}}) - 1]. \quad (2.755)$$

The variable of integration b coincides with the impact parameter b introduced in Eq. (1.500). The result (2.755) is precisely the eikonal approximation (1.500) with $\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}}/2$ playing the role of the scattering phases $\delta_l(p)$ of angular momentum $l = pb/\hbar$:

$$\chi_{\mathbf{b},\mathbf{p}}^{\text{ei}} = 2i\delta_{pb/\hbar}(p). \quad (2.756)$$

2.23 Heisenberg Operator Approach to Time Evolution Amplitude

An interesting alternative to the path integral derivation of the time evolution amplitudes of harmonic systems is based on quantum mechanics in the Heisenberg picture. It bears a close similarity with the path integral derivation in that it requires solving the classical equations of motion with given initial and final positions to obtain the exponential of the classical action $e^{iA/\hbar}$. The fluctuation factor, however, which accompanies this exponential is obtained quite differently from commutation rules of the operatorial orbits at different times as we shall now demonstrate.

2.23.1 Free Particle

We want to calculate the matrix element of the time evolution operator

$$\langle \mathbf{x} t | \mathbf{x}' 0 \rangle = \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle, \quad (2.757)$$

where \hat{H} is the Hamiltonian operator

$$\hat{H} = H(\hat{\mathbf{p}}) = \frac{\hat{\mathbf{p}}^2}{2M}. \quad (2.758)$$

We shall calculate the time evolution amplitude (2.757) by solving the differential equation

$$\begin{aligned} i\hbar\partial_t \langle \mathbf{x} t | \mathbf{x}' 0 \rangle &\equiv \langle \mathbf{x} | \hat{H} e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} \left[e^{i\hat{H}t/\hbar} \hat{H} e^{-i\hat{H}t/\hbar} \right] | \mathbf{x}' \rangle \\ &= \langle \mathbf{x} t | H(\hat{\mathbf{p}}(t)) | \mathbf{x}' 0 \rangle. \end{aligned} \quad (2.759)$$

The argument contains now the time-dependent Heisenberg picture of the operator $\hat{\mathbf{p}}$. The evaluation of the right-hand side will be based on re-expressing the operator $H(\hat{\mathbf{p}}(t))$ as a function of initial and final position operators in such a way that all final position operators stand to the left of all initial ones:

$$\hat{H} = H(\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0); t). \quad (2.760)$$

Then the matrix elements on the right-hand side can immediately be evaluated using the eigenvalue equations

$$\langle \mathbf{x} t | \hat{\mathbf{x}}(t) = \mathbf{x} \langle \mathbf{x} t |, \quad \hat{\mathbf{x}}(0) | \mathbf{x}' 0 \rangle = \mathbf{x}' | \mathbf{x}' 0 \rangle, \quad (2.761)$$

as being

$$\langle \mathbf{x} t | H(\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0); t) | \hat{\mathbf{x}} 0 \rangle = H(\mathbf{x}, \mathbf{x}'; t) \langle \mathbf{x} t | \mathbf{x}' 0 \rangle, \quad (2.762)$$

and the differential equation (2.759) becomes

$$i\hbar\partial_t \langle \mathbf{x} t | \mathbf{x}' 0 \rangle \equiv H(\mathbf{x}, \mathbf{x}'; t) \langle \mathbf{x} t | \mathbf{x}' 0 \rangle, \quad (2.763)$$

or

$$\langle \mathbf{x} t | \mathbf{x}' 0 \rangle = C(\mathbf{x}, \mathbf{x}') E(\mathbf{x}, \mathbf{x}'; t) \equiv C(\mathbf{x}, \mathbf{x}') e^{-i \int_t dt' H(\mathbf{x}, \mathbf{x}'; t')/\hbar}. \quad (2.764)$$

The prefactor $C(\mathbf{x}, \mathbf{x}')$ contains a possible constant of integration resulting from the time integral in the exponent.

The Hamiltonian operator is brought to the time-ordered form (2.760) by solving the Heisenberg equations of motion

$$\frac{d\hat{\mathbf{x}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{x}}(t)] = \frac{\hat{\mathbf{p}}(t)}{M}, \quad (2.765)$$

$$\frac{d\hat{\mathbf{p}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{p}}(t)] = 0. \quad (2.766)$$

The second equation shows that the momentum is time-independent:

$$\hat{\mathbf{p}}(t) = \hat{\mathbf{p}}(0), \quad (2.767)$$

so that the first equation is solved by

$$\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0) = t \frac{\hat{\mathbf{p}}(t)}{M}, \quad (2.768)$$

which brings (2.758) to

$$\hat{H} = \frac{M}{2t^2} [\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0)]^2. \quad (2.769)$$

This is not yet the desired form (2.760) since there is one factor which is not time-ordered. The proper order is achieved by rewriting \hat{H} as

$$\hat{H} = \frac{M}{2t^2} \{ \hat{\mathbf{x}}^2(t) - 2\hat{\mathbf{x}}(t)\hat{\mathbf{x}}(0) + \hat{\mathbf{x}}^2(0) + [\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0)] \}, \quad (2.770)$$

and calculating the commutator from Eq. (2.768) and the canonical commutation rule $[\hat{p}_i, \hat{x}_j] = -i\hbar\delta_{ij}$ as

$$[\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0)] = -\frac{i\hbar}{M}Dt, \quad (2.771)$$

so that we find the desired expression

$$\hat{H} = H(\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0); t) = \frac{M}{2t^2} [\hat{\mathbf{x}}^2(t) - 2\hat{\mathbf{x}}(t)\hat{\mathbf{x}}(0) + \hat{\mathbf{x}}^2(0)] - i\hbar\frac{D}{2t}. \quad (2.772)$$

Its matrix elements (2.762) can now immediately be written down:

$$H(\mathbf{x}, \mathbf{x}'; t) = \frac{M}{2t^2} (\mathbf{x} - \mathbf{x}')^2 - i\hbar\frac{D}{2t}. \quad (2.773)$$

From this we find directly the exponential factor in (2.764)

$$E(\mathbf{x}, \mathbf{x}'; t) = e^{-i \int dt H(\mathbf{x}, \mathbf{x}'; t)/\hbar} = \exp \left[\frac{i}{\hbar} \frac{M}{2t} (\mathbf{x} - \mathbf{x}')^2 - \frac{D}{2} \log t \right]. \quad (2.774)$$

Inserting (2.774) into Eq. (2.764), we obtain

$$\langle \mathbf{x}t | \mathbf{x}'0 \rangle = C(\mathbf{x}, \mathbf{x}') \frac{1}{t^{D/2}} \exp \left[\frac{i}{\hbar} \frac{M}{2t} (\mathbf{x} - \mathbf{x}')^2 \right]. \quad (2.775)$$

A possible constant of integration in (2.774) depending on \mathbf{x}, \mathbf{x}' is absorbed in the prefactor $C(\mathbf{x}, \mathbf{x}')$. This is fixed by differential equations involving \mathbf{x} :

$$\begin{aligned} -i\hbar\nabla \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \langle \mathbf{x} | \hat{\mathbf{p}} e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \langle \mathbf{x} | e^{-i\hat{H}t} \left[e^{i\hat{H}t/\hbar} \hat{\mathbf{p}} e^{-i\hat{H}t/\hbar} \right] | \mathbf{x}' \rangle = \langle \mathbf{x}t | \hat{\mathbf{p}}(t) | \mathbf{x}'0 \rangle. \\ i\hbar\nabla' \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} \hat{\mathbf{p}} | \mathbf{x}' \rangle = \langle \mathbf{x}t | \hat{\mathbf{p}}(0) | \mathbf{x}'0 \rangle. \end{aligned} \quad (2.776)$$

Inserting (2.768) and using the momentum conservation (2.767), these become

$$\begin{aligned} -i\hbar\nabla \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \frac{M}{t} (\mathbf{x} - \mathbf{x}') \langle \mathbf{x}t | \mathbf{x}'0 \rangle, \\ i\hbar\nabla' \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \frac{M}{t} (\mathbf{x} - \mathbf{x}') \langle \mathbf{x}t | \mathbf{x}'0 \rangle. \end{aligned} \quad (2.777)$$

Inserting here the previous result (2.775), we obtain the conditions

$$-i\nabla C(\mathbf{x}, \mathbf{x}') = 0, \quad i\nabla' C(\mathbf{x}, \mathbf{x}') = 0, \quad (2.778)$$

which are solved only by a constant C . The constant, in turn, is fixed by the initial condition

$$\lim_{t \rightarrow 0} \langle \mathbf{x}t | \mathbf{x}'0 \rangle = \delta^{(D)}(\mathbf{x} - \mathbf{x}'), \quad (2.779)$$

to be

$$C = \sqrt{\frac{M}{2\pi i\hbar}}^D, \quad (2.780)$$

so that we find the correct free-particle amplitude (2.74)

$$\langle \mathbf{x}t | \mathbf{x}'0 \rangle \equiv \sqrt{\frac{M}{2\pi i\hbar t}}^D \exp \left[\frac{i}{\hbar} \frac{M}{2t} (\mathbf{x} - \mathbf{x}')^2 \right]. \quad (2.781)$$

Note that the fluctuation factor $1/t^{D/2}$ emerges in this approach as a consequence of the commutation relation (2.771).

2.23.2 Harmonic Oscillator

Here we are dealing with the Hamiltonian operator

$$\hat{H} = H(\hat{\mathbf{p}}, \hat{\mathbf{x}}) = \frac{\hat{\mathbf{p}}^2}{2M} + \frac{M\omega^2}{2}\mathbf{x}^2, \quad (2.782)$$

which has to be brought again to the time-ordered form (2.760). We must now solve the Heisenberg equations of motion

$$\frac{d\hat{\mathbf{x}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{x}}(t)] = \frac{\hat{\mathbf{p}}(t)}{M}, \quad (2.783)$$

$$\frac{d\hat{\mathbf{p}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{p}}(t)] = -M\omega^2\hat{\mathbf{x}}(t). \quad (2.784)$$

By solving these equations we obtain [compare (2.158)]

$$\hat{\mathbf{p}}(t) = M \frac{\omega}{\sin \omega t} [\hat{\mathbf{x}}(t) \cos \omega t - \hat{\mathbf{x}}(0)]. \quad (2.785)$$

Inserting this into (2.782), we obtain

$$\hat{H} = \frac{M\omega^2}{2\sin^2 \omega t} \left\{ [\hat{\mathbf{x}}(t) \cos \omega t - \hat{\mathbf{x}}(0)]^2 + \sin^2 \omega t \hat{\mathbf{x}}^2(t) \right\}, \quad (2.786)$$

which is equal to

$$\hat{H} = \frac{M\omega^2}{2\sin^2 \omega t} \left\{ \hat{\mathbf{x}}^2(t) + \hat{\mathbf{x}}^2(0) - 2 \cos \omega t \hat{\mathbf{x}}(t)\hat{\mathbf{x}}(0) + \cos \omega t [\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0)] \right\}. \quad (2.787)$$

By commuting Eq. (2.785) with $\hat{\mathbf{x}}(t)$, we find the commutator [compare (2.771)]

$$[\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0)] = -\frac{i\hbar}{M} D \frac{\sin \omega t}{\omega}, \quad (2.788)$$

so that we find the matrix elements of the Hamiltonian operator in the form (2.762) [compare (2.773)]

$$H(\mathbf{x}, \mathbf{x}'; t) = \frac{M\omega^2}{2\sin^2 \omega t} \left(\mathbf{x}^2 + \mathbf{x}'^2 - 2 \cos \omega t \mathbf{x}\mathbf{x}' \right) - i\hbar \frac{D}{2} \omega \cot \omega t. \quad (2.789)$$

This has the integral [compare (2.774)]

$$\int dt H(\mathbf{x}, \mathbf{x}'; t) = -\frac{M\omega}{2\sin \omega t} \left[(\mathbf{x}^2 + \mathbf{x}'^2) \cos \omega t - 2 \mathbf{x}\mathbf{x}' \right] - i\hbar \frac{D}{2} \log \frac{\sin \omega t}{\omega}. \quad (2.790)$$

Inserting this into Eq. (2.764), we find precisely the harmonic oscillator amplitude (2.177), apart from the factor $C(\mathbf{x}, \mathbf{x}')$. This is again determined by the differential equations (2.776), leaving only a simple normalization factor fixed by the initial condition (2.779) with the result (2.780).

Again, the fluctuation factor has its origin in the commutator (2.788).

2.23.3 Charged Particle in Magnetic Field

We now turn to a charged particle in three dimensions in a magnetic field treated in Section 2.18, where the Hamiltonian operator is most conveniently expressed in terms of the operator of the covariant momentum (2.644),

$$\hat{\mathbf{P}} \equiv \hat{\mathbf{p}} - \frac{e}{c} \mathbf{A}(\hat{\mathbf{x}}), \quad (2.791)$$

as [compare (2.643)]

$$\hat{H} = H(\hat{\mathbf{p}}, \hat{\mathbf{x}}) = \frac{\hat{\mathbf{P}}^2}{2M}. \quad (2.792)$$

In the presence of a magnetic field, its components do not commute but satisfy the commutation rules:

$$[\hat{P}_i, \hat{P}_j] = -\frac{e}{c} [\hat{p}_i, \hat{A}_j] - \frac{e}{c} [\hat{A}_i, \hat{p}_j] = i \frac{e\hbar}{c} (\nabla_i A_j - \nabla_j A_i) = i \frac{e\hbar}{c} B_{ij}, \quad (2.793)$$

where $B_{ij} = \epsilon_{ijk} B_K$ is the usual antisymmetric tensor representation of the magnetic field.

We now have to solve the Heisenberg equations of motion

$$\frac{d\hat{\mathbf{x}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{x}}(t)] = \frac{\hat{\mathbf{P}}(t)}{M} \quad (2.794)$$

$$\frac{d\hat{\mathbf{P}}(t)}{dt} = \frac{i}{\hbar} [\hat{H}, \hat{\mathbf{P}}(t)] = \frac{e}{Mc} B(\hat{\mathbf{x}}(t)) \hat{\mathbf{P}}(t) + i \frac{e\hbar}{Mc} \nabla_j B_{ji}(\hat{\mathbf{x}}(t)), \quad (2.795)$$

where $B(\hat{\mathbf{x}}(t))\hat{\mathbf{P}}(t)$ is understood as the product of the matrix $B_{ij}(\hat{\mathbf{x}}(t))$ with the vector $\hat{\mathbf{P}}$. In a *constant* field, where $B_{ij}(\hat{\mathbf{x}}(t))$ is a constant matrix B_{ij} , the last term in the second equation is absent and we find directly the solution

$$\hat{\mathbf{P}}(t) = e^{\Omega_L t} \hat{\mathbf{P}}(0), \quad (2.796)$$

where Ω_L is a matrix version of the Landau frequency (2.648)

$$\Omega_L{}_{ij} \equiv \frac{e}{Mc} B_{ij}, \quad (2.797)$$

which can also be rewritten with the help of the Landau frequency vector

$$\boldsymbol{\omega}_L \equiv \frac{e}{Mc} \mathbf{B} \quad (2.798)$$

and the 3×3 -generators of the rotation group

$$(L_k)_{ij} \equiv -i\epsilon_{kij} \quad (2.799)$$

as

$$\Omega_L = i \mathbf{L} \cdot \boldsymbol{\omega}_L. \quad (2.800)$$

Inserting this into Eq. (2.794), we find

$$\hat{\mathbf{x}}(t) = \hat{\mathbf{x}}(0) + \frac{e^{\Omega_L t} - 1}{\Omega_L} \frac{\hat{\mathbf{P}}(0)}{M}, \quad (2.801)$$

where the matrix on the right-hand side is again defined by a power series expansion

$$\frac{e^{\Omega_L t} - 1}{\Omega_L} = t + \Omega_L \frac{t^2}{2} + \Omega_L^2 \frac{t^3}{3!} + \dots \quad (2.802)$$

We can invert (2.801) to find

$$\frac{\hat{\mathbf{P}}(0)}{M} = \frac{\Omega_L/2}{\sinh \Omega_L t/2} e^{-\Omega_L t/2} [\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0)]. \quad (2.803)$$

Using (2.796), this implies

$$\hat{\mathbf{P}}(t) = MN(\Omega_L t) [\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0)], \quad (2.804)$$

with the matrix

$$N(\Omega_L t) \equiv \frac{\Omega_L/2}{\sinh \Omega_L t/2} e^{\Omega_L t/2}. \quad (2.805)$$

By squaring (2.804) we obtain

$$\frac{\hat{\mathbf{P}}^2(t)}{2M} = \frac{M}{2} [\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0)]^T K(\Omega_L t) [\hat{\mathbf{x}}(t) - \hat{\mathbf{x}}(0)], \quad (2.806)$$

where

$$K(\Omega_L t) = N^T(\Omega_L t) N(\Omega_L t). \quad (2.807)$$

Using the antisymmetry of the matrix Ω_L , we can rewrite this as

$$K(\Omega_L t) = N(-\Omega_L t) N(\Omega_L t) = \frac{\Omega_L^2/4}{\sinh^2 \Omega_L t/2}. \quad (2.808)$$

The commutator between two operators $\hat{\mathbf{x}}(t)$ at different times is, due to Eq. (2.801),

$$[\hat{\mathbf{x}}_i(t), \hat{\mathbf{x}}_j(0)] = -\frac{i}{M} \left(\frac{e^{\Omega_L t} - 1}{\Omega_L} \right)_{ij}, \quad (2.809)$$

and

$$\begin{aligned} [\hat{\mathbf{x}}_i(t), \hat{\mathbf{x}}_j(0)] + [\hat{\mathbf{x}}_j(t), \hat{\mathbf{x}}_i(0)] &= -\frac{i}{M} \left(\frac{e^{\Omega_L t} - 1}{\Omega_L} + \frac{e^{\Omega_L^T t} - 1}{\Omega_L^T} \right)_{ij} \\ &= -\frac{i}{M} \left(\frac{e^{\Omega_L t} - e^{-\Omega_L t}}{\Omega_L} \right)_{ij} = -2\frac{i}{M} \left[\frac{\sinh \Omega_L t}{\Omega_L} \right]_{ij}. \end{aligned} \quad (2.810)$$

Respecting this, we can expand (2.806) in powers of operators $\hat{\mathbf{x}}(t)$ and $\hat{\mathbf{x}}(0)$, thereby time-ordering the later operators to the left of the earlier ones as follows:

$$\begin{aligned} H(\hat{\mathbf{x}}(t), \hat{\mathbf{x}}(0)) &= \frac{M}{2} [\hat{\mathbf{x}}^T(t) K(\Omega_L t) \hat{\mathbf{x}}(t) - 2\hat{\mathbf{x}}^T K(\Omega_L t) \hat{\mathbf{x}}(0) + \hat{\mathbf{x}}^T K(\Omega_L t) \hat{\mathbf{x}}(0)] \\ &\quad - \frac{i\hbar}{2} \text{tr} \left[\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right]. \end{aligned} \quad (2.811)$$

This has to be integrated in t , for which we use the formulas

$$\int dt K(\Omega_L t) = \int dt \frac{\Omega_L^2/2}{\sinh^2 \Omega_L t/2} = -\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2}, \quad (2.812)$$

and

$$\int dt \frac{1}{2} \text{tr} \left[\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right] = \text{tr} \log \frac{\sinh \Omega_L t/2}{\Omega_L/2} = \text{tr} \log \frac{\sinh \Omega_L t/2}{\Omega_L t/2} + 3 \log t, \quad (2.813)$$

these results following again from a Taylor expansion of both sides. The factor 3 in the last term is due to the three-dimensional trace. We can then immediately write down the exponential factor $E(\mathbf{x}, \mathbf{x}'; t)$ in (2.764):

$$E(\mathbf{x}, \mathbf{x}'; t) = \frac{1}{t^{3/2}} \exp \left\{ \frac{i}{\hbar} \frac{M}{2} (\mathbf{x} - \mathbf{x}')^T \left(\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right) (\mathbf{x} - \mathbf{x}') - \frac{1}{2} \text{tr} \log \frac{\sinh \Omega_L t/2}{\Omega_L t/2} \right\}. \quad (2.814)$$

The last term gives rise to a prefactor

$$\left[\det \frac{\sinh \Omega_L t/2}{\Omega_L t/2} \right]^{-1/2}. \quad (2.815)$$

As before, the time-independent integration factor $C(\mathbf{x}, \mathbf{x}')$ in (2.764) is fixed by differential equations in \mathbf{x} and \mathbf{x}' , which involve here the covariant derivatives:

$$\begin{aligned} \left[-i\hbar\nabla - \frac{e}{c}\mathbf{A}(\mathbf{x}) \right] \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \langle \mathbf{x} | \hat{\mathbf{P}} e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} \left[e^{i\hat{H}t/\hbar} \hat{\mathbf{P}} e^{-i\hat{H}t/\hbar} \right] | \mathbf{x}' \rangle \\ &= \langle \mathbf{x}t | \hat{\mathbf{P}}(t) | \mathbf{x}'0 \rangle = L(\Omega_L t)(\mathbf{x} - \mathbf{x}') \langle \mathbf{x}t | \mathbf{x}'0 \rangle, \end{aligned} \quad (2.816)$$

$$\begin{aligned} \left[i\hbar\nabla' - \frac{e}{c}\mathbf{A}(\mathbf{x}') \right] \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} \hat{\mathbf{P}} | \mathbf{x}' \rangle \\ &= \langle \mathbf{x}t | \hat{\mathbf{P}}(0) | \mathbf{x}'0 \rangle = L(\Omega_L t)(\mathbf{x} - \mathbf{x}') \langle \mathbf{x}t | \mathbf{x}'0 \rangle. \end{aligned} \quad (2.817)$$

Calculating the partial derivative we find

$$\begin{aligned} -i\hbar\nabla \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= [-i\hbar\nabla C(\mathbf{x}, \mathbf{x}')] E(\mathbf{x}, \mathbf{x}'; t) + C(\mathbf{x}, \mathbf{x}') [-i\hbar\nabla E(\mathbf{x}, \mathbf{x}'; t)] \\ &= [-i\hbar\nabla C(\mathbf{x}, \mathbf{x}')] E(\mathbf{x}, \mathbf{x}'; t) + C(\mathbf{x}, \mathbf{x}') M \left(\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right) (\mathbf{x} - \mathbf{x}') E(\mathbf{x}, \mathbf{x}'; t). \end{aligned}$$

Subtracting the right-hand side of (2.816) leads to

$$M \left(\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right) (\mathbf{x} - \mathbf{x}') - ML(\Omega_L t)(\mathbf{x} - \mathbf{x}') = -\frac{M}{2}\Omega_L(\mathbf{x} - \mathbf{x}'), \quad (2.818)$$

so that $C(\mathbf{x}, \mathbf{x}')$ satisfies the time-independent differential equation

$$\left[-i\hbar\nabla - \frac{e}{c}\mathbf{A}(\mathbf{x}) - \frac{M}{2}\Omega_L(\mathbf{x} - \mathbf{x}') \right] C(\mathbf{x}, \mathbf{x}') = 0. \quad (2.819)$$

A similar equation is found from the second equation (2.817):

$$\left[i\hbar\nabla' - \frac{e}{c}\mathbf{A}(\mathbf{x}') - \frac{M}{2}\Omega_L(\mathbf{x} - \mathbf{x}') \right] C(\mathbf{x}, \mathbf{x}') = 0. \quad (2.820)$$

These equations are solved by

$$C(\mathbf{x}, \mathbf{x}') = C \exp \left\{ \frac{i}{\hbar} \int_{\mathbf{x}'}^{\mathbf{x}} d\boldsymbol{\xi} \left[\frac{e}{c}\mathbf{A}(\boldsymbol{\xi}) + \frac{M}{2}\Omega_L(\boldsymbol{\xi} - \mathbf{x}') \right] \right\}. \quad (2.821)$$

The contour of integration is arbitrary since the vector field in brackets,

$$\frac{e}{c}\mathbf{A}'(\boldsymbol{\xi}) \equiv \frac{e}{c}\mathbf{A}(\boldsymbol{\xi}) + \frac{\Omega_L}{2}(\boldsymbol{\xi} - \mathbf{x}') = \frac{e}{c} \left[\mathbf{A}(\boldsymbol{\xi}) - \frac{1}{2}\mathbf{B} \times (\boldsymbol{\xi} - \mathbf{x}') \right] \quad (2.822)$$

has a vanishing curl, $\nabla \times \mathbf{A}'(\mathbf{x}) = 0$. We can therefore choose the contour to be a straight line connecting \mathbf{x}' and \mathbf{x} , in which case $d\boldsymbol{\xi}$ points in the same direction of $\mathbf{x} - \mathbf{x}'$ as $\boldsymbol{\xi} - \mathbf{x}'$ so that the cross product vanishes. Hence we may write for a straight-line connection the Ω_L -term

$$C(\mathbf{x}, \mathbf{x}') = C \exp \left\{ i \frac{e}{c} \int_{\mathbf{x}'}^{\mathbf{x}} d\boldsymbol{\xi} \mathbf{A}(\boldsymbol{\xi}) \right\}. \quad (2.823)$$

Finally, the normalization constant C is fixed by the initial condition (2.779) to have the value (2.780).

Collecting all terms, the amplitude is

$$\begin{aligned} \langle \mathbf{x}t | \mathbf{x}'0 \rangle &= \frac{1}{\sqrt{2\pi i\hbar^2 t/M}} \left[\det \frac{\sinh \Omega_L t/2}{\Omega_L t/2} \right]^{-1/2} \exp \left\{ i \frac{e}{c} \int_{\mathbf{x}'}^{\mathbf{x}} d\boldsymbol{\xi} \mathbf{A}(\boldsymbol{\xi}) \right\} \\ &\times \exp \left\{ \frac{i}{\hbar} \frac{M}{2} (\mathbf{x} - \mathbf{x}')^T \left(\frac{\Omega_L}{2} \coth \frac{\Omega_L t}{2} \right) (\mathbf{x} - \mathbf{x}') \right\}. \end{aligned} \quad (2.824)$$

All expressions simplify if we assume the magnetic field to point in the z -direction, in which case the frequency matrix becomes

$$\Omega_L = \begin{pmatrix} 0 & \omega_L & 0 \\ -\omega_L & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (2.825)$$

so that

$$\cos \frac{\Omega_L t}{2} = \begin{pmatrix} \cos \omega_L t/2 & 0 & 0 \\ 0 & \cos \omega_L t/2 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (2.826)$$

and

$$\frac{\sinh \Omega_L t/2}{\Omega_L t/2} = \begin{pmatrix} 0 & \sin \omega_L t/2 & 0 \\ -\sin \omega_L t/2 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (2.827)$$

whose determinant is

$$\det \frac{\sinh \Omega_L t/2}{\Omega_L t/2} = \left(\frac{\sinh \omega_L t/2}{\omega_L t/2} \right)^2. \quad (2.828)$$

Let us calculate the exponential involving the vector potential in (2.824) explicitly. We choose the gauge in which the vector potential points in the y -direction [recall (2.636)], and parametrize the straight line between \mathbf{x}' and \mathbf{x} as

$$\boldsymbol{\xi} = \mathbf{x}' + s(\mathbf{x} - \mathbf{x}'), \quad s \in [0, 1]. \quad (2.829)$$

Then we find

$$\begin{aligned} \int_{\mathbf{x}'}^{\mathbf{x}} d\boldsymbol{\xi} \mathbf{A}(\boldsymbol{\xi}) &= B(y - y') \int_0^1 ds [x' + s(x - x')] = B(y - y')(x + x') \\ &= B(xy - x'y') + B(x'y - xy'). \end{aligned} \quad (2.830)$$

Inserting this and (2.828) into (2.764), we recover the earlier result (2.668).

Appendix 2A Baker-Campbell-Hausdorff Formula and Magnus Expansion

The standard Baker-Campbell-Hausdorff formula, from which our formula (2.9) can be derived, reads

$$e^{\hat{A}} e^{\hat{B}} = e^{\hat{C}}, \quad (2A.1)$$

where

$$\hat{C} = \hat{B} + \int_0^1 dt g(e^{\text{ad} \hat{A} t} e^{\text{ad} \hat{B}}) [\hat{A}], \quad (2A.2)$$

and $g(z)$ is the function

$$g(z) \equiv \frac{\log z}{z - 1} = \sum_{n=0}^{\infty} \frac{(1 - z)^n}{n + 1}, \quad (2A.3)$$

and $\text{ad} B$ is the operator associated with \hat{B} in the so-called *adjoint representation*, which is defined by

$$\text{ad} B[\hat{A}] \equiv [\hat{B}, \hat{A}]. \quad (2A.4)$$

One also defines the trivial adjoint operator $(\text{ad } B)^0[\hat{A}] = 1[\hat{A}] \equiv \hat{A}$. By expanding the exponentials in Eq. (2A.2) and using the power series (2A.3), one finds the explicit formula

$$\hat{C} = \hat{B} + \hat{A} + \sum_{n=1}^{\infty} \frac{(-1)^n}{n+1} \sum_{p_i, q_i; p_i+q_i \geq 1} \frac{1}{1 + \sum_{i=1}^n p_i} \times \frac{(\text{ad } A)^{p_1}}{p_1!} \frac{(\text{ad } B)^{q_1}}{q_1!} \dots \frac{(\text{ad } A)^{p_n}}{p_n!} \frac{(\text{ad } B)^{q_n}}{q_n!} [\hat{A}]. \quad (2A.5)$$

The lowest expansion terms are

$$\begin{aligned} \hat{C} &= \hat{B} + \hat{A} - \frac{1}{2} \left[\frac{1}{2} \text{ad } A + \text{ad } B + \frac{1}{6} (\text{ad } A)^2 + \frac{1}{2} \text{ad } A \text{ad } B + \frac{1}{2} (\text{ad } B)^2 + \dots \right] [\hat{A}] \\ &\quad + \frac{1}{3} \left[\frac{1}{3} (\text{ad } A)^2 + \frac{1}{2} \text{ad } A \text{ad } B + \frac{1}{2} \text{ad } B \text{ad } A + (\text{ad } B)^2 + \dots \right] [\hat{A}] \\ &= \hat{A} + \hat{B} + \frac{1}{2} [\hat{A}, \hat{B}] + \frac{1}{12} ([\hat{A}, [\hat{A}, \hat{B}]] + [\hat{B}, [\hat{B}, \hat{A}]]) + \frac{1}{24} [\hat{A}, [[\hat{A}, \hat{B}], \hat{B}]] \dots \end{aligned} \quad (2A.6)$$

The result can be rearranged to the closely related *Zassenhaus formula*

$$e^{\hat{A}+\hat{B}} = e^{\hat{A}} e^{\hat{B}} e^{\hat{Z}_2} e^{\hat{Z}_3} e^{\hat{Z}_4} \dots, \quad (2A.7)$$

where

$$\hat{Z}_2 = \frac{1}{2} [\hat{B}, \hat{A}] \quad (2A.8)$$

$$\hat{Z}_3 = -\frac{1}{3} [\hat{B}, [\hat{B}, \hat{A}]] - \frac{1}{6} [\hat{A}, [\hat{B}, \hat{A}]] \quad (2A.9)$$

$$\hat{Z}_4 = \frac{1}{8} \left([[[\hat{B}, \hat{A}], \hat{B}], \hat{B}] + [[[\hat{B}, \hat{A}], \hat{A}], \hat{B}] \right) + \frac{1}{24} [[[\hat{B}, \hat{A}], \hat{A}], \hat{A}] \quad (2A.10)$$

\vdots

To prove formula (2A.2) and thus the expansion (2A.6), we proceed similar to the derivation of the interaction formula (1.295) by deriving and solving a differential equation for the operator function

$$\hat{C}(t) = \log(e^{\hat{A}t} e^{\hat{B}}). \quad (2A.11)$$

Its value at $t = 1$ will supply us with the desired result \hat{C} in (2A.5). The starting point is the observation that for any operator \hat{M} ,

$$e^{\hat{C}(t)} \hat{M} e^{-\hat{C}(t)} = e^{\text{ad } \hat{C}(t)} [\hat{M}], \quad (2A.12)$$

by definition of $\text{ad } C$. Inserting (2A.11), the left-hand side can also be rewritten as $e^{\hat{A}t} e^{\hat{B}} \hat{M} e^{-\hat{B}} e^{-\hat{A}t}$, which in turn is equal to $e^{\text{ad } A t} e^{\text{ad } B} [\hat{M}]$, by definition (2A.4). Hence we have

$$e^{\text{ad } C(t)} = e^{\text{ad } A t} e^{\text{ad } B}. \quad (2A.13)$$

Differentiation of (2A.11) yields

$$e^{\hat{C}(t)} \frac{d}{dt} e^{-\hat{C}(t)} = -\hat{A}. \quad (2A.14)$$

The left-hand side, on the other hand, can be rewritten in general as

$$e^{\hat{C}(t)} \frac{d}{dt} e^{-\hat{C}(t)} = -f(\text{ad } C(t)) [\dot{\hat{C}}(t)], \quad (2A.15)$$

where

$$f(z) \equiv \frac{e^z - 1}{z}. \quad (2A.16)$$

This will be verified below. It implies that

$$f(\text{ad}C(t))[\dot{\hat{C}}(t)] = \hat{A}. \quad (2A.17)$$

We now define the function $g(z)$ as in (2A.3) and see that it satisfies

$$g(e^z)f(z) \equiv 1. \quad (2A.18)$$

We therefore have the trivial identity

$$\dot{\hat{C}}(t) = g(e^{\text{ad}C(t)})f(\text{ad}C(t))[\dot{\hat{C}}(t)]. \quad (2A.19)$$

Using (2A.17) and (2A.13), this turns into the differential equation

$$\dot{\hat{C}}(t) = g(e^{\text{ad}C(t)})[\hat{A}] = e^{\text{ad}At}e^{\text{ad}B}[\hat{A}], \quad (2A.20)$$

from which we find directly the result (2A.2).

To complete the proof we must verify (2A.15). The expression is not simply equal to $-e^{\hat{C}(t)}\dot{\hat{C}}(t)Me^{-\hat{C}(t)}$ since $\dot{\hat{C}}(t)$ does not, in general, commute with $\hat{C}(t)$. To account for this consider the operator

$$\hat{O}(s, t) \equiv e^{\hat{C}(t)s} \frac{d}{dt} e^{-\hat{C}(t)s}. \quad (2A.21)$$

Differentiating this with respect to s gives

$$\begin{aligned} \partial_s \hat{O}(s, t) &= e^{\hat{C}(t)s} \hat{C}(t) \frac{d}{dt} (e^{-\hat{C}(t)s}) - e^{\hat{C}(t)s} \frac{d}{dt} (\hat{C}(t) e^{-\hat{C}(t)s}) \\ &= -e^{\hat{C}(t)s} \dot{\hat{C}}(t) e^{-\hat{C}(t)s} \\ &= -e^{\text{ad}C(t)s} [\dot{\hat{C}}(t)]. \end{aligned} \quad (2A.22)$$

Hence

$$\begin{aligned} \hat{O}(s, t) - \hat{O}(0, t) &= \int_0^s ds' \partial_{s'} \hat{O}(s', t) \\ &= - \sum_{n=0}^{\infty} \frac{s^{n+1}}{(n+1)!} (\text{ad}C(t))^n [\dot{\hat{C}}(t)], \end{aligned} \quad (2A.23)$$

from which we obtain

$$\hat{O}(1, t) = e^{\hat{C}(t)} \frac{d}{dt} e^{-\hat{C}(t)} = -f(\text{ad}C(t))[\dot{\hat{C}}(t)], \quad (2A.24)$$

which is what we wanted to prove.

Note that the final form of the series for \hat{C} in (2A.6) can be rearranged in many different ways, using the Jacobi identity for the commutators. It is a nontrivial task to find a form involving the smallest number of terms.³⁹

The same mathematical technique can be used to derive a useful modification of the Neumann-Liouville expansion or Dyson series (1.239) and (1.251). This is the so-called *Magnus expansion*⁴⁰, in which one writes $\hat{U}(t_b, t_a) = e^{\hat{E}}$, and expands the exponent \hat{E} as

$$\hat{E} = -\frac{i}{\hbar} \int_{t_a}^{t_b} dt_1 \hat{H}(t_1) + \frac{1}{2} \left(\frac{-i}{\hbar} \right)^2 \int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_2} dt_1 [\hat{H}(t_2), \hat{H}(t_1)]$$

³⁹For a discussion see J.A. Oteo, J. Math. Phys. *32*, 419 (1991).

⁴⁰See A. Iserles, A. Marthinsen, and S.P. Norsett, *On the implementation of the method of Magnus series for linear differential equations*, BIT **39**, 281 (1999) (<http://www.damtp.cam.ac.uk/user/ai/Publications>).

$$+ \frac{1}{4} \left(\frac{-i}{\hbar} \right)^3 \left\{ \int_{t_a}^{t_b} dt_3 \int_{t_a}^{t_3} dt_2 \int_{t_a}^{t_2} dt_1 \left[\hat{H}(t_3), \left[\hat{H}(t_2), \hat{H}(t_1) \right] \right] \right. \\ \left. + \frac{1}{3} \int_{t_a}^{t_b} dt_3 \int_{t_a}^{t_3} dt_2 \int_{t_a}^{t_2} dt_1 \left[\left[\hat{H}(t_3), \hat{H}(t_2) \right], \hat{H}(t_1) \right] \right\} + \dots, \quad (2A.25)$$

which converges faster than the Neumann-Liouville expansion.

Appendix 2B Direct Calculation of the Time-Sliced Oscillator Amplitude

After time-slicing, the amplitude (2.145) becomes a multiple integral over short-time amplitudes [using the action (2.192)]

$$(x_n \epsilon | x_{n-1} 0) = \frac{1}{\sqrt{2\pi\hbar i \epsilon / M}} \exp \left\{ \frac{i}{\hbar} \frac{M}{2} \left[\frac{(x_n - x_{n-1})^2}{\epsilon} - \epsilon \omega^2 \frac{1}{2} (x_n^2 + x_{n-1}^2) \right] \right\}. \quad (2B.26)$$

We shall write this as

$$(x_n \epsilon | x_{n-1} 0) = \mathcal{N}_1 \exp \left\{ \frac{i}{\hbar} [a_1(x_n^2 + x_{n-1}^2) - 2b_1 x_n x_{n-1}] \right\}, \quad (2B.27)$$

with

$$a_1 = \frac{M}{2\epsilon} \left[1 - 2 \left(\frac{\omega \epsilon}{2} \right)^2 \right], \quad b_1 = \frac{M}{2\epsilon}, \\ \mathcal{N}_1 = \frac{1}{\sqrt{2\pi\hbar i \epsilon / M}}. \quad (2B.28)$$

When performing the intermediate integrations in a product of N such amplitudes, the result must have the same general form

$$(x_N \epsilon | x_{N-1} 0) = \mathcal{N}_N \exp \left\{ \frac{i}{\hbar} [a_N(x_N^2 + x_0^2) - 2b_N x_N x_0] \right\}. \quad (2B.29)$$

Multiplying this by a further short-time amplitude and integrating over the intermediate position gives the recursion relations

$$\mathcal{N}_{N+1} = \mathcal{N}_1 \mathcal{N}_N \sqrt{\frac{i\pi\hbar}{a_N + a_1}}, \quad (2B.30)$$

$$a_{N+1} = \frac{a_N^2 - b_N^2 + a_1 a_N}{a_1 + a_N} = \frac{a_1^2 - b_1^2 + a_1 a_N}{a_1 + a_N}, \quad (2B.31)$$

$$b_{N+1} = \frac{b_1 b_N}{a_1 + a_N}. \quad (2B.32)$$

From (2B.31) we find

$$a_N^2 = b_N^2 + a_1^2 - b_1^2, \quad (2B.33)$$

and the only nontrivial recursion relation to be solved is that for b_N . With (2B.32) it becomes

$$b_{N+1} = \frac{b_1 b_N}{a_1 + \sqrt{b_N^2 - (b_1^2 - a_1^2)}}, \quad (2B.34)$$

or

$$\frac{1}{b_{N+1}} = \frac{1}{b_1} \left(\frac{a_1}{b_N} + \sqrt{1 - \frac{b_1^2 - a_1^2}{b_N^2}} \right). \quad (2B.35)$$

We now introduce the auxiliary frequency $\tilde{\omega}$ of Eq. (2.163). Then

$$a_1 = \frac{M}{2\epsilon} \cos \tilde{\omega}, \quad (2B.36)$$

and the recursion for b_{N+1} reads

$$\frac{1}{b_{N+1}} = \frac{\cos \tilde{\omega}\epsilon}{b_N} + \frac{2\epsilon}{M} \sqrt{1 - \frac{M^2 \sin^2 \tilde{\omega}\epsilon}{4\epsilon^2 b_N^2}}. \quad (2B.37)$$

By introducing the reduced quantities

$$\beta_N \equiv \frac{2\epsilon}{M} b_N, \quad (2B.38)$$

with

$$\beta_1 = 1, \quad (2B.39)$$

the recursion becomes

$$\frac{1}{\beta_{N+1}} = \frac{\cos \tilde{\omega}\epsilon}{\beta_N} + \sqrt{1 - \frac{\sin^2 \tilde{\omega}\epsilon}{\beta_N^2}}. \quad (2B.40)$$

For $N = 1, 2$, this determines

$$\begin{aligned} \frac{1}{\beta_2} &= \cos \tilde{\omega}\epsilon + \sqrt{1 - \sin^2 \tilde{\omega}\epsilon} = \frac{\sin 2\tilde{\omega}\epsilon}{\sin \tilde{\omega}\epsilon}, \\ \frac{1}{\beta_3} &= \cos \tilde{\omega}\epsilon \frac{\sin 2\tilde{\omega}\epsilon}{\sin \tilde{\omega}\epsilon} + \sqrt{1 - \sin^2 \tilde{\omega}\epsilon} \frac{\sin^2 2\tilde{\omega}\epsilon}{\sin^2 \tilde{\omega}\epsilon} = \frac{\sin 3\tilde{\omega}\epsilon}{\sin \tilde{\omega}\epsilon}. \end{aligned} \quad (2B.41)$$

We therefore expect the general result

$$\frac{1}{\beta_{N+1}} = \frac{\sin \tilde{\omega}(N+1)\epsilon}{\sin \tilde{\omega}\epsilon}. \quad (2B.42)$$

It is easy to verify that this solves the recursion relation (2B.40). From (2B.38) we thus obtain

$$b_{N+1} = \frac{M}{2\epsilon} \frac{\sin \tilde{\omega}\epsilon}{\sin \tilde{\omega}(N+1)\epsilon}. \quad (2B.43)$$

Inserting this into (2B.30) and (2B.33) yields

$$a_{N+1} = \frac{M}{2\epsilon} \sin \tilde{\omega}\epsilon \frac{\cos \tilde{\omega}(N+1)\epsilon}{\sin \tilde{\omega}(N+1)\epsilon}, \quad (2B.44)$$

$$\mathcal{N}_{N+1} = \mathcal{N}_1 \sqrt{\frac{\sin \tilde{\omega}\epsilon}{\sin \tilde{\omega}(N+1)\epsilon}}, \quad (2B.45)$$

such that (2B.29) becomes the time-sliced amplitude (2.199).

Appendix 2C Derivation of Mehler Formula

Here we briefly sketch the derivation of Mehler's formula.⁴¹ It is based on the observation that the left-hand side of Eq. (2.297), let us call it $F(x, x')$, is the Fourier transform of the function

$$\tilde{F}(k, k') = \pi e^{-(k^2 + k'^2 + akk')/2}, \quad (2C.46)$$

⁴¹See P.M. Morse and H. Feshbach, *Methods of Theoretical Physics*, McGraw-Hill, New York, Vol. I, p. 781 (1953).

as can easily be verified by performing the two Gaussian integrals in the Fourier representation

$$F(x; x') = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dk}{2\pi} \frac{dk'}{2\pi} e^{ikx+ik'x} \tilde{F}(k, k'). \quad (2C.47)$$

We now consider the right-hand side of (2.297) and form the Fourier transform by recognizing the exponential $e^{k^2/2-ikx}$ as the generating function of the Hermite polynomials⁴²

$$e^{k^2/2-ikx} = \sum_{n=0}^{\infty} \frac{(-ik/2)^n}{n!} H_n(x). \quad (2C.48)$$

This leads to

$$\begin{aligned} \tilde{F}(k, k') &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dx dx' F(x, x') e^{-ikx-ik'x} = e^{-(k^2+k'^2)/2} \\ &\times \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dx dx' F(x, x') \sum_{n=0}^{\infty} \sum_{n'=0}^{\infty} \frac{(-ik/2)^n}{n!} \frac{(-ik'/2)^{n'}}{n'!} H_n(x) H_{n'}(x). \end{aligned} \quad (2C.49)$$

Inserting here the expansion on the right-hand side of (2.297) and using the orthogonality relation of Hermite polynomials (2.306), we obtain once more (2C.47).

Notes and References

The basic observation underlying path integrals for time evolution amplitudes goes back to the historic article

P.A.M. Dirac, *Physikalische Zeitschrift der Sowjetunion* **3**, 64 (1933).

He observed that the short-time propagator is the exponential of i/\hbar times the classical action. See also

External Sources, Correlations, and Perturbation Theory

Important information on every quantum-mechanical system is carried by the correlation functions of the path $x(t)$. They are defined as the expectation values of products of path positions at different times, $x(t_1) \cdots x(t_n)$, to be calculated as functional averages. Quantities of this type are observable in simple scattering experiments. The most efficient extraction of correlation functions from a path integral proceeds by adding to the Lagrangian an external time-dependent mechanical force term disturbing the system linearly, and by studying the response to the disturbance. A similar linear term is used extensively in quantum field theory, for instance in quantum electrodynamics where it is no longer a mechanical force, but a source of fields, i.e., a charge or a current density. For this reason we shall call this term generically source or current term.

In this chapter, the procedure is developed for the harmonic action, where a linear source term does not destroy the solvability of the path integral. The resulting amplitude is a simple functional of the current. Its functional derivatives will supply all correlation functions of the system, and for this reason it is called the *generating functional* of the theory. It serves to derive the celebrated *Wick rule* for calculating the correlation functions of an arbitrary number of $x(t)$. This forms the basis for perturbation expansions of anharmonic theories.

3.1 External Sources

Consider a harmonic oscillator with an action

$$\mathcal{A}_\omega = \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}^2 - \omega^2 x^2). \quad (3.1)$$

Let it be disturbed by an external *source* or *current* $j(t)$ coupled linearly to the particle coordinate $x(t)$. The source action is

$$\mathcal{A}_j = \int_{t_a}^{t_b} dt x(t)j(t). \quad (3.2)$$

The total action

$$\mathcal{A} = \mathcal{A}_\omega + \mathcal{A}_j \quad (3.3)$$

is still harmonic in x and \dot{x} , which makes it is easy to solve the path integral in the presence of a source term. In particular, the source term does not destroy the factorization property (2.153) of the time evolution amplitude into a classical amplitude $e^{i\mathcal{A}_{j,\text{cl}}/\hbar}$ and a fluctuation factor $F_{\omega,j}(t_b, t_a)$,
 ref(2.153) lab(2.111) est(2.128)

$$(x_b t_b | x_a t_a)_\omega^j = e^{(i/\hbar)\mathcal{A}_{j,\text{cl}}} F_{\omega,j}(t_b, t_a). \quad (3.4)$$

Here $\mathcal{A}_{j,\text{cl}}$ is the action for the classical orbit $x_{j,\text{cl}}(t)$ which minimizes the total action \mathcal{A} in the presence of the source term and which obeys the equation of motion

$$\ddot{x}_{j,\text{cl}}(t) + \omega^2 x_{j,\text{cl}}(t) = j(t). \quad (3.5)$$

In the sequel, we shall first work with the classical orbit $x_{\text{cl}}(t)$ extremizing the action *without* the source term:

$$x_{\text{cl}}(t) = \frac{x_b \sin \omega(t - t_a) + x_a \sin \omega(t_b - t)}{\sin \omega(t_b - t_a)}. \quad (3.6)$$

All paths will be written as a sum of the classical orbit $x_{\text{cl}}(t)$ and a fluctuation $\delta x(t)$:

$$x(t) = x_{\text{cl}}(t) + \delta x(t). \quad (3.7)$$

Then the action separates into a classical and a fluctuating part, each of which contains a source-free and a source term:

$$\begin{aligned} \mathcal{A} = \mathcal{A}_\omega + \mathcal{A}_j &\equiv \mathcal{A}_{\text{cl}} + \mathcal{A}_{\text{fl}} \\ &= (\mathcal{A}_{\omega,\text{cl}} + \mathcal{A}_{j,\text{cl}}) + (\mathcal{A}_{\omega,\text{fl}} + \mathcal{A}_{j,\text{fl}}). \end{aligned} \quad (3.8)$$

The time evolution amplitude can be expressed as

$$\begin{aligned} (x_b t_b | x_a t_a)_\omega^j &= e^{(i/\hbar)\mathcal{A}_{\text{cl}}} \int \mathcal{D}x \exp\left(\frac{i}{\hbar}\mathcal{A}_{\text{fl}}\right) \\ &= e^{(i/\hbar)(\mathcal{A}_{\omega,\text{cl}} + \mathcal{A}_{j,\text{cl}})} \int \mathcal{D}x \exp\left[\frac{i}{\hbar}(\mathcal{A}_{\omega,\text{fl}} + \mathcal{A}_{j,\text{fl}})\right]. \end{aligned} \quad (3.9)$$

ref(2.159) The classical action $\mathcal{A}_{\omega,\text{cl}}$ is known from Eq. (2.159):

lab(2.116)

est(2.133)

$$\mathcal{A}_{\omega,\text{cl}} = \frac{M\omega}{2 \sin \omega(t_b - t_a)} \left[(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a \right]. \quad (3.10)$$

The classical source term is known from (3.6):

$$\begin{aligned} \mathcal{A}_{j,\text{cl}} &= \int_{t_a}^{t_b} dt x_{\text{cl}}(t) j(t) \\ &= \frac{1}{\sin \omega(t_b - t_a)} \int_{t_a}^{t_b} dt [x_a \sin \omega(t_b - t) + x_b \sin \omega(t - t_a)] j(t). \end{aligned} \quad (3.11)$$

Consider now the fluctuating part of the action, $\mathcal{A}_{\text{fl}} = \mathcal{A}_{\omega, \text{fl}} + \mathcal{A}_{j, \text{fl}}$. Since $x_{\text{cl}}(t)$ extremizes the action without the source, \mathcal{A}_{fl} contains a term linear in $\delta x(t)$. After a partial integration [making use of the vanishing of $\delta x(t)$ at the ends] it can be written as

$$\mathcal{A}_{\text{fl}} = \frac{M}{2} \int_{t_a}^{t_b} dt dt' \delta x(t) D_{\omega^2}(t, t') \delta x(t') + \int_{t_a}^{t_b} dt \delta x(t) j(t), \quad (3.12)$$

where $D_{\omega^2}(t, t')$ is the differential operator

$$D_{\omega^2}(t, t') = (-\partial_t^2 - \omega^2) \delta(t - t') = \delta(t - t') (-\partial_{t'}^2 - \omega^2), \quad t, t' \in (t_a, t_b). \quad (3.13)$$

It may be considered as a functional matrix in the space of the t -dependent functions vanishing at t_a, t_b . The equality of the two expressions is seen as follows. By partial integrations one has

$$\int_{t_a}^{t_b} dt f(t) \partial_t^2 g(t) = \int_{t_a}^{t_b} dt \partial_t^2 f(t) g(t), \quad (3.14)$$

for any $f(t)$ and $g(t)$ vanishing at the boundaries (or for periodic functions in the interval). The left-hand side can directly be rewritten as $\int_{t_a}^{t_b} dt dt' f(t) \delta(t - t') \partial_{t'}^2 g(t')$, the right-hand side as $\int_{t_a}^{t_b} dt dt' \partial_t^2 f(t) \delta(t - t') g(t')$, and after further partial integrations, as $\int dt dt' f(t) \partial_t^2 \delta(t - t') g(t)$.

The inverse $D_{\omega^2}^{-1}(t, t')$ of the functional matrix (3.13) is formally defined by the relation

$$\int_{t_a}^{t_b} dt' D_{\omega^2}(t'', t') D_{\omega^2}^{-1}(t', t) = \delta(t'' - t), \quad t'', t \in (t_a, t_b), \quad (3.15)$$

which shows that it is the standard classical Green function of the harmonic oscillator of frequency ω :

$$G_{\omega^2}(t, t') \equiv D_{\omega^2}^{-1}(t, t') = (-\partial_t^2 - \omega^2)^{-1} \delta(t - t'), \quad t, t' \in (t_a, t_b). \quad (3.16)$$

This definition is not unique since it leaves room for an additional arbitrary solution $H(t, t')$ of the homogeneous equation $\int_{t_a}^{t_b} dt' D_{\omega^2}(t'', t') H(t', t) = 0$. This freedom will be removed below by imposing appropriate boundary conditions.

In the fluctuation action (3.12), we now perform a *quadratic completion* by a shift of $\delta x(t)$ to

$$\delta \tilde{x}(t) \equiv \delta x(t) + \frac{1}{M} \int_{t_a}^{t_b} dt' G_{\omega^2}(t, t') j(t'). \quad (3.17)$$

Then the action becomes quadratic in both $\delta \tilde{x}$ and j :

$$\mathcal{A}_{\text{fl}} = \int_{t_a}^{t_b} dt \int_{t_a}^{t_b} dt' \left[\frac{M}{2} \delta \tilde{x}(t) D_{\omega^2}(t, t') \delta \tilde{x}(t') - \frac{1}{2M} j(t) G_{\omega^2}(t, t') j(t') \right]. \quad (3.18)$$

The Green function obeys the same boundary condition as the fluctuations $\delta x(t)$:

$$G_{\omega^2}(t, t') = 0 \quad \text{for} \quad \begin{cases} t = t_b, & t' \text{ arbitrary,} \\ t \text{ arbitrary,} & t' = t_a. \end{cases} \quad (3.19)$$

Thus, the shifted fluctuations $\delta\tilde{x}(t)$ of (3.17) also vanish at the ends and run through the same functional space as the original $\delta x(t)$. The measure of path integration $\int \mathcal{D}\delta x(t)$ is obviously unchanged by the simple shift (3.17). Hence the path integral $\int \mathcal{D}\delta\tilde{x}$ over $e^{i\mathcal{A}_{\text{fl}}/\hbar}$ with the action (3.18) gives, via the first term in \mathcal{A}_{fl} , the harmonic fluctuation factor $F_{\omega}(t_b - t_a)$ calculated in (2.171):

ref(2.171)
lab(2.125)
est(2.144)

$$F_{\omega}(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}}. \quad (3.20)$$

The source part in (3.18) contributes only a trivial exponential factor

$$F_{j,\text{fl}} = \exp \left\{ \frac{i}{\hbar} \mathcal{A}_{j,\text{fl}} \right\}, \quad (3.21)$$

whose exponent is quadratic in $j(t)$:

$$\mathcal{A}_{j,\text{fl}} = -\frac{1}{2M} \int_{t_a}^{t_b} dt \int_{t_a}^{t_b} dt' j(t) G_{\omega^2}(t, t') j(t'). \quad (3.22)$$

The total time evolution amplitude in the presence of a source term can therefore be written as the product

$$(x_b t_b | x_a t_a)_{\omega}^j = (x_b t_b | x_a t_a)_{\omega} F_{j,\text{cl}} F_{j,\text{fl}}, \quad (3.23)$$

where $(x_b t_b | x_a t_a)_{\omega}$ is the source-free time evolution amplitude

$$(x_b t_b | x_a t_a)_{\omega} = e^{(i/\hbar)\mathcal{A}_{\omega,\text{cl}}} F_{\omega}(t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}} \\ \times \exp \left\{ \frac{i}{2\hbar} \frac{M\omega}{\sin \omega(t_b - t_a)} [(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a] \right\}, \quad (3.24)$$

and $F_{j,\text{cl}}$ is an amplitude containing the classical action (3.11):

$$F_{j,\text{cl}} = e^{(i/\hbar)\mathcal{A}_{j,\text{cl}}} \\ = \exp \left\{ \frac{i}{\hbar} \frac{1}{\sin \omega(t_b - t_a)} \int_{t_a}^{t_b} dt [x_a \sin \omega(t_b - t) + x_b \sin \omega(t - t_a)] j(t) \right\}. \quad (3.25)$$

To complete the result we need to know the Green function $G_{\omega^2}(t, t')$ explicitly, which will be calculated in the next section.

3.2 Green Function of Harmonic Oscillator

According to Eq. (3.16), the Green function in Eq. (3.22) is obtained by inverting the second-order differential operator $-\partial_t^2 - \omega^2$:

$$G_{\omega^2}(t, t') = (-\partial_t^2 - \omega^2)^{-1} \delta(t - t'), \quad t, t' \in (t_a, t_b). \quad (3.26)$$

As remarked above, this function is defined only up to solutions of the homogeneous differential equation associated with the operator $-\partial_t^2 - \omega^2$. The boundary conditions removing this ambiguity are the same as for the fluctuations $\delta x(t)$, i.e., $G_{\omega^2}(t, t')$ vanishes if either t or t' or both hit an endpoint t_a or t_b (Dirichlet boundary condition). The Green function is symmetric in t and t' . For the sake of generality, we shall find the Green function also for the more general differential equation with time-dependent frequency,

$$[-\partial_t^2 - \Omega^2(t)]G_{\Omega^2}(t, t') = \delta(t - t'), \quad (3.27)$$

with the same boundary conditions.

There are several ways of calculating this explicitly.

3.2.1 Wronski Construction

The simplest way proceeds via the so-called *Wronski construction*, which is based on the following observation. For different time arguments, $t > t'$ or $t < t'$, the Green function $G_{\Omega^2}(t, t')$ has to solve the homogeneous differential equations

$$(-\partial_t^2 - \omega^2)G_{\Omega^2}(t, t') = 0, \quad (-\partial_{t'}^2 - \omega^2)G_{\Omega^2}(t, t') = 0. \quad (3.28)$$

It must therefore be a linear combination of two independent solutions of the homogeneous differential equation in t as well as in t' , and it must satisfy the Dirichlet boundary condition of vanishing at the respective endpoints.

Constant Frequency

If $\Omega^2(t) \equiv \omega^2$, this implies that for $t > t'$, $G_{\omega^2}(t, t')$ must be proportional to $\sin \omega(t_b - t)$ as well as to $\sin \omega(t' - t_a)$, leaving only the solution

$$G_{\omega^2}(t, t') = C \sin \omega(t_b - t) \sin \omega(t' - t_a), \quad t > t'. \quad (3.29)$$

For $t < t'$, we obtain similarly

$$G_{\omega^2}(t, t') = C \sin \omega(t_b - t') \sin \omega(t - t_a), \quad t < t'. \quad (3.30)$$

The two cases can be written as a single expression

$$G_{\omega^2}(t, t') = C \sin \omega(t_b - t_{>}) \sin \omega(t_{<} - t_a), \quad (3.31)$$

where the symbols $t_>$ and $t_<$ denote the larger and the smaller of the times t and t' , respectively. The unknown constant C is fixed by considering coincident times $t = t'$. There, the time derivative of $G_{\omega^2}(t, t')$ must have a discontinuity which gives rise to the δ -function in (3.15). For $t > t'$, the derivative of (3.29) is

$$\partial_t G_{\omega^2}(t, t') = -C\omega \cos \omega(t_b - t) \sin \omega(t' - t_a), \quad (3.32)$$

whereas for $t < t'$

$$\partial_t G_{\omega^2}(t, t') = C\omega \sin \omega(t_b - t') \cos \omega(t - t_a). \quad (3.33)$$

At $t = t'$ we find the discontinuity

$$\partial_t G_{\omega^2}(t, t')|_{t=t'+\epsilon} - \partial_t G_{\omega^2}(t, t')|_{t=t'-\epsilon} = -C\omega \sin \omega(t_b - t_a). \quad (3.34)$$

Hence $-\partial_t^2 G_{\omega^2}(t, t')$ is proportional to a δ -function:

$$-\partial_t^2 G_{\omega^2}(t, t') = C\omega \sin \omega(t_b - t_a) \delta(t - t'). \quad (3.35)$$

By normalizing the prefactor to unity, we fix C and find the desired Green function:

$$G_{\omega^2}(t, t') = \frac{\sin \omega(t_b - t_>) \sin \omega(t_< - t_a)}{\omega \sin \omega(t_b - t_a)}. \quad (3.36)$$

It exists only if $t_b - t_a$ is not equal to an integer multiple of π/ω . This restriction was encountered before in the amplitude without external sources; its meaning was

ref(2.168) discussed in the two paragraphs following Eq. (2.168).

lab(x2.142) The constant in the denominator of (3.36) is the Wronski determinant (or *Wron-*
est(2.142) *skian*) of the two solutions $\xi(t) = \sin \omega(t_b - t)$ and $\eta(t) = \sin \omega(t - t_a)$ which was

ref(2.222) introduced in (2.222):

lab(2.171)

est(2.194)

$$W[\xi(t), \eta(t)] \equiv \xi(t)\dot{\eta}(t) - \dot{\xi}(t)\eta(t). \quad (3.37)$$

An alternative expression for (3.36) is

$$G_{\omega^2}(t, t') = \frac{-\cos \omega(t_b - t_a - |t - t'|) + \cos \omega(t_b + t_a - t - t')}{2\omega \sin \omega(t_b - t_a)}. \quad (3.38)$$

In the limit $\omega \rightarrow 0$ we obtain the free-particle Green function

$$\begin{aligned} G_0(t, t') &= \frac{1}{(t_b - t_a)}(t_b - t_>)(t_< - t_a) \\ &= \frac{1}{t_b - t_a} \left[-tt' - \frac{1}{2}(t_b - t_a)|t - t'| + \frac{1}{2}(t_a + t_b)(t + t') - t_a t_b \right]. \end{aligned} \quad (3.39)$$

Time-Dependent Frequency

It is just as easy to find the Green functions of the more general differential equation (3.27) with a time-dependent oscillator frequency $\Omega(t)$. We construct first a so-called *retarded Green function* (compare page 38) as a product of a Heaviside function with a smooth function

$$G_{\Omega^2}(t, t') = \Theta(t - t')\Delta(t, t'). \quad (3.40)$$

Inserting this into the differential equation (3.27) we find

$$\begin{aligned} [-\partial_t^2 - \Omega^2(t)]G_{\Omega^2}(t, t') &= \Theta(t - t') [-\partial_t^2 - \Omega^2(t)]\Delta(t, t') \\ &- \dot{\delta}(t - t') - 2\partial_t\Delta(t, t')\delta(t - t'). \end{aligned} \quad (3.41)$$

Expanding

$$\Delta(t, t') = \Delta(t, t) + [\partial_t\Delta(t, t')]_{t=t'}(t - t') + \frac{1}{2}[\partial_t^2\Delta(t, t')]_{t=t'}(t - t')^2 + \dots, \quad (3.42)$$

and using the fact that

$$(t - t')\dot{\delta}(t - t') = -\delta(t - t'), \quad (t - t')^n\dot{\delta}(t - t') = 0 \quad \text{for } n > 1, \quad (3.43)$$

the second line in (3.41) can be rewritten as

$$-\dot{\delta}(t - t')\Delta(t, t') - \delta(t - t')\partial_t\Delta(t, t'). \quad (3.44)$$

By choosing the initial conditions

$$\Delta(t, t) = 0, \quad \dot{\Delta}(t, t')|_{t'=t} = -1, \quad (3.45)$$

we satisfy the inhomogeneous differential equation (3.27) provided $\Delta(t, t')$ obeys the homogeneous differential equation

$$[-\partial_t^2 - \Omega^2(t)]\Delta(t, t') = 0, \quad \text{for } t > t'. \quad (3.46)$$

This equation is solved by a linear combination

$$\Delta(t, t') = \alpha(t')\xi(t) + \beta(t')\eta(t) \quad (3.47)$$

of any two independent solutions $\eta(t)$ and $\xi(t)$ of the homogeneous equation

$$[-\partial_t^2 - \Omega^2(t)]\xi(t) = 0, \quad [-\partial_t^2 - \Omega^2(t)]\eta(t) = 0. \quad (3.48)$$

Their Wronski determinant $W = \xi(t)\dot{\eta}(t) - \dot{\xi}(t)\eta(t)$ is nonzero and, of course, time-independent, so that we can determine the coefficients in the linear combination (3.47) from (3.45) and find

$$\Delta(t, t') = \frac{1}{W} [\xi(t)\eta(t') - \xi(t')\eta(t)]. \quad (3.49)$$

The right-hand side contains the so-called Jacobi commutator of the two functions $\xi(t)$ and $\eta(t)$. Here we list a few useful algebraic properties of $\Delta(t, t')$:

$$\Delta(t, t') = \frac{\Delta(t_b, t)\Delta(t', t_a) - \Delta(t, t_a)\Delta(t_b, t')}{\Delta(t_b, t_a)}, \quad (3.50)$$

$$\Delta(t_b, t)\partial_{t_b} \Delta(t_b, t_a) - \Delta(t, t_a) = \Delta(t_b, t_a)\partial_t \Delta(t_b, t), \quad (3.51)$$

$$\Delta(t, t_a)\partial_{t_b} \Delta(t_b, t_a) - \Delta(t_b, t) = \Delta(t_b, t_a)\partial_t \Delta(t, t_a). \quad (3.52)$$

The retarded Green function (3.40) is so far not the unique solution of the differential equation (3.27), since one may always add a general solution of the homogeneous differential equation (3.48):

$$G_{\Omega^2}(t, t') = \Theta(t - t')\Delta(t, t') + a(t')\xi(t) + b(t')\eta(t), \quad (3.53)$$

with arbitrary coefficients $a(t')$ and $b(t')$. This ambiguity is removed by the Dirichlet boundary conditions

$$\begin{aligned} G_{\Omega^2}(t_b, t) &= 0, & t_b \neq t, \\ G_{\Omega^2}(t, t_a) &= 0, & t \neq t_a. \end{aligned} \quad (3.54)$$

Imposing these upon (3.53) leads to a simple algebraic pair of equations

$$a(t)\xi(t_a) + b(t)\eta(t_a) = 0, \quad (3.55)$$

$$a(t)\xi(t_b) + b(t)\eta(t_b) = \Delta(t, t_b). \quad (3.56)$$

Denoting the 2×2 -coefficient matrix by

$$\Lambda = \begin{pmatrix} \xi(t_a) & \eta(t_a) \\ \xi(t_b) & \eta(t_b) \end{pmatrix}, \quad (3.57)$$

we observe that under the condition

$$\det \Lambda = W\Delta(t_a, t_b) \neq 0, \quad (3.58)$$

the system (3.56) has a unique solution for the coefficients $a(t)$ and $b(t)$ in the Green function (3.53). Inserting this into (3.54) and using the identity (3.50), we obtain from this Wronski's general formula corresponding to (3.36)

$$G_{\Omega^2}(t, t') = \frac{\Theta(t - t')\Delta(t_b, t)\Delta(t', t_a) + \Theta(t' - t)\Delta(t, t_a)\Delta(t_b, t')}{\Delta(t_a, t_b)}. \quad (3.59)$$

At this point it is useful to realize that the functions in the numerator coincide with the two specific linearly independent solutions $D_a(t)$ and $D_b(t)$ of the homogeneous differential equations (3.48) which were introduced in Eqs. (2.228) and (2.229). Comparing the initial conditions of $D_a(t)$ and $D_b(t)$ with that of the function $\Delta(t, t')$ in Eq. (3.45), we readily identify

$$D_a(t) \equiv \Delta(t, t_a), \quad D_b(t) \equiv \Delta(t_b, t), \quad (3.60)$$

and formula (3.59) can be rewritten as

$$G_{\Omega^2}(t, t') = \frac{\Theta(t - t')D_b(t)D_a(t') + \Theta(t' - t)D_a(t)D_b(t')}{D_a(t_b)}. \quad (3.61)$$

It should be pointed out that this equation renders a unique and well-defined Green function if the differential equation $[-\partial_t^2 - \Omega^2(t)]y(t) = 0$ has no solutions with Dirichlet boundary conditions $y(t_a) = y(t_b) = 0$, generally called *zero-modes*. A zero mode would cause problems since it would certainly be one of the independent solutions of (3.49), say $\eta(t)$. Due to the property $\eta(t_a) = \eta(t_b) = 0$, however, the determinant of Λ would vanish, thus destroying the condition (3.58) which was necessary to find (3.59). Indeed, the function $\Delta(t, t')$ in (3.49) would remain undetermined since the boundary condition $\eta(t_a) = 0$ together with (3.55) implies that also $\xi(t_a) = 0$, making $W = \xi(t)\dot{\eta}(t) - \dot{\xi}(t)\eta(t)$ vanish at the initial time t_a , and thus for all times.

3.2.2 Spectral Representation

A second way of specifying the Green function explicitly is via its *spectral representation*.

Constant Frequency

For constant frequency $\Omega(t) \equiv \omega$, the fluctuations $\delta x(t)$ which satisfy the differential equation

$$(-\partial_t^2 - \omega^2)\delta x(t) = 0, \quad (3.62)$$

and vanish at the ends $t = t_a$ and $t = t_b$, are expanded into a complete set of orthonormal functions:

$$x_n(t) = \sqrt{\frac{2}{t_b - t_a}} \sin \nu_n(t - t_a), \quad (3.63)$$

with the frequencies [compare (2.115)]

$$\nu_n = \frac{\pi n}{t_b - t_a}. \quad (3.64)$$

These functions satisfy the orthonormality relations

$$\int_{t_a}^{t_b} dt x_n(t)x_{n'}(t) = \delta_{nn'}. \quad (3.65)$$

Since the operator $-\partial_t^2 - \omega^2$ is diagonal on $x_n(t)$, this is also true for the Green function $G_{\omega^2}(t, t') = (-\partial_t^2 - \omega^2)^{-1}\delta(t - t')$. Let G_n be its eigenvalues defined by

$$\int_{t_a}^{t_b} dt G_{\omega^2}(t, t')x_n(t') = G_n x_n(t). \quad (3.66)$$

Then we expand $G_{\omega^2}(t, t')$ as follows:

$$G_{\omega^2}(t, t') = \sum_{n=1}^{\infty} G_n x_n(t) x_n(t'). \quad (3.67)$$

By definition, the eigenvalues of $G_{\omega^2}(t, t')$ are the inverse eigenvalues of the differential operator $(-\partial_t^2 - \omega^2)$, which are $\nu_n^2 - \omega^2$. Thus

$$G_n = (\nu_n^2 - \omega^2)^{-1}, \quad (3.68)$$

and we arrive at the spectral representation of $G_{\omega^2}(t, t')$:

$$G_{\omega^2}(t, t') = \frac{2}{t_b - t_a} \sum_{n=1}^{\infty} \frac{\sin \nu_n(t - t_a) \sin \nu_n(t' - t_a)}{\nu_n^2 - \omega^2}. \quad (3.69)$$

We may use the trigonometric relation

$$\sin \nu_n(t_b - t) = -\sin \nu_n[(t - t_a) - (t_b - t_a)] = -(-1)^n \sin \nu_n(t - t_a)$$

to rewrite (3.69) as

$$G_{\omega^2}(t, t') = \frac{2}{t_b - t_a} \sum_{n=1}^{\infty} (-1)^{n+1} \frac{\sin \nu_n(t_b - t) \sin \nu_n(t' - t_a)}{\nu_n^2 - \omega^2}. \quad (3.70)$$

These expressions make sense only if $t_b - t_a$ is not equal to an integer multiple of π/ω , where one of the denominators in the sums vanishes. This is the same range of $t_b - t_a$ as in the Wronski expression (3.36).

Time-Dependent Frequency

The spectral representation can also be written down for the more general Green function with a time-dependent frequency defined by the differential equation (3.27). If $y_n(t)$ are the eigenfunctions solving the differential equation with eigenvalue λ_n

$$K(t)y_n(t) = \lambda_n y_n(t), \quad (3.71)$$

and if these eigenfunctions satisfy the orthogonality and completeness relations

$$\int_{t_a}^{t_b} dt y_n(t) y_{n'}(t) = \delta_{nn'}, \quad (3.72)$$

$$\sum_n y_n(t) y_n(t') = \delta(t - t'), \quad (3.73)$$

and if, moreover, there exists no zero-mode for which $\lambda_n = 0$, then $G_{\Omega^2}(t, t')$ has the spectral representation

$$G_{\Omega^2}(t, t') = \sum_n \frac{y_n(t) y_n(t')}{\lambda_n}. \quad (3.74)$$

This is easily verified by multiplication with $K(t)$ using (3.71) and (3.73).

It is instructive to prove the equality between the Wronskian construction and the spectral representations (3.36) and (3.70). It will be useful to do this in several steps. In the present context, some of these may appear redundant. They will, however, yield intermediate results which will be needed in Chapters 7 and 18 when discussing path integrals occurring in quantum field theories.

3.3 Green Functions of First-Order Differential Equation

An important quantity of statistical mechanics are the Green functions $G_{\Omega}^{\text{p}}(t, t')$ which solve the *first-order* differential equation

$$[i\partial_t - \Omega(t)] G_{\Omega}(t, t') = i\delta(t - t'), \quad t - t' \in [0, t_b - t_a], \quad (3.75)$$

or its Euclidean version $G_{\Omega, \text{e}}^{\text{p}}(\tau, \tau')$ which solves the differential equation, obtained from (3.75) for $t = -i\tau$:

$$[\partial_{\tau} - \Omega(\tau)] G_{\Omega, \text{e}}(\tau, \tau') = \delta(\tau - \tau'), \quad \tau - \tau' \in [0, \hbar\beta). \quad (3.76)$$

These can be calculated for an arbitrary function $\Omega(t)$.

3.3.1 Time-Independent Frequency

Consider first the simplest case of a Green function $G_{\omega}^{\text{p}}(t, t')$ with fixed frequency ω which solves the *first-order* differential equation

$$(i\partial_t - \omega)G_{\omega}^{\text{p}}(t, t') = i\delta(t - t'), \quad t - t' \in [0, t_b - t_a). \quad (3.77)$$

The equation determines $G_{\omega}^{\text{p}}(t, t')$ only up to a solution $H(t, t')$ of the homogeneous differential equation $(i\partial_t - \omega)H(t, t') = 0$. The ambiguity is removed by imposing the *periodic* boundary condition

$$G_{\omega}^{\text{p}}(t, t') \equiv G_{\omega}^{\text{p}}(t - t') = G_{\omega}^{\text{p}}(t - t' + t_b - t_a), \quad (3.78)$$

indicated by the superscript p. With this boundary condition, the Green function $G_{\omega}^{\text{p}}(t, t')$ is translationally invariant in time. It depends only on the difference between t and t' and is periodic in it.

The spectral representation of $G_{\omega}^{\text{p}}(t, t')$ can immediately be written down, assuming that $t_b - t_a$ does not coincide with an even multiple of π/ω :

$$G_{\omega}^{\text{p}}(t - t') = \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} e^{-i\omega_m(t-t')} \frac{i}{\omega_m - \omega}. \quad (3.79)$$

The frequencies ω_m are twice as large as the previous ν_m 's in (3.64):

$$\omega_m \equiv \frac{2\pi m}{t_b - t_a}, \quad m = 0, \pm 1, \pm 2, \pm 3, \dots \quad (3.80)$$

As for the periodic orbits in Section 2.9, there are “about as many” ω_m as ν_m , since there is an ω_m for each positive *and* negative integer m , whereas the ν_m are all positive (see the last paragraph in that section). The frequencies (3.80) are the real-time analogs of the Matsubara frequencies (2.381) of quantum statistics with the usual correspondence $t_b - t_a = -i\hbar/k_B T$ of Eq. (2.330).

To calculate the spectral sum, we use the Poisson summation formula in the form (1.197):

ref(2.381)
lab(2.213)
est(2.252)
ref(2.330)
lab(2.180)
est(2.213)
ref(1.197)
lab(2c.226)
est(2.322)

$$\sum_{m=-\infty}^{\infty} f(m) = \int_{-\infty}^{\infty} d\mu \sum_{n=-\infty}^{\infty} e^{2\pi i \mu n} f(\mu). \quad (3.81)$$

Accordingly, we rewrite the sum over ω_m as an integral over ω' , followed by an auxiliary sum over n which squeezes the variable ω' onto the proper discrete values $\omega_m = 2\pi m/(t_b - t_a)$:

$$G_{\omega}^p(t) = \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{-i\omega'[t-(t_b-t_a)n]} \frac{i}{\omega' - \omega}. \quad (3.82)$$

At this point it is useful to introduce another Green function $G_{\omega}(t-t')$ associated with the first-order differential equation (3.77) on an *infinite* time interval:

$$G_{\omega}(t) = \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{-i\omega't} \frac{i}{\omega' - \omega}. \quad (3.83)$$

In terms of this function, the periodic Green function (3.82) can be written as a sum which exhibits in a most obvious way the periodicity under $t \rightarrow t + (t_b - t_a)$:

$$G_{\omega}^p(t) = \sum_{n=-\infty}^{\infty} G_{\omega}(t - (t_b - t_a)n). \quad (3.84)$$

The advantage of using $G_{\omega}(t-t')$ is that the integral over ω' in (3.83) can easily be done. We merely have to prescribe how to treat the singularity at $\omega' = \omega$. This also removes the freedom of adding a homogeneous solution $H(t, t')$. To make the integral unique, we replace ω by $\omega - i\eta$ where η is a very small positive number, i.e., by the $i\eta$ -prescription introduced after Eq. (2.168). This moves the pole in the integrand of (3.83) into the lower half of the complex ω' -plane, making the integral over ω' in $G_{\omega}(t)$ fundamentally different for $t < 0$ and for $t > 0$. For $t < 0$, the contour of integration can be closed in the complex ω' -plane by a semicircle in the *upper* half-plane at no extra cost, since $e^{-i\omega't}$ is exponentially small there (see Fig. 3.1). With the integrand being analytic in the upper half-plane we can contract the contour to zero and find that the integral vanishes. For $t > 0$, on the other hand, the contour is closed in the lower half-plane containing a pole at $\omega' = \omega - i\eta$. When contracting the contour to zero, the integral picks up the residue at this pole and yields a factor $-2\pi i$. At the point $t = 0$, finally, we can close the contour either way. The integral over the semicircles is now nonzero, $\mp 1/2$, which has to be subtracted from the residues 0 and 1, respectively, yielding $1/2$. Hence we find

$$\begin{aligned} G_{\omega}(t) &= \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} e^{-i\omega't} \frac{i}{\omega' - \omega + i\eta} \\ &= e^{-i\omega t} \times \begin{cases} 1 & \text{for } t > 0, \\ \frac{1}{2} & \text{for } t = 0, \\ 0 & \text{for } t < 0. \end{cases} \end{aligned} \quad (3.85)$$

The vanishing of the Green function for $t < 0$ is the *causality property* of $G_{\omega}(t)$ discussed in (1.310) and (1.311). It is a general property of functions whose Fourier

Figure 3.1 Pole in Fourier transform of Green functions $G_{\omega}^{\text{p,a}}(t)$, and infinite semicircles in the upper (lower) half-plane which extend the integrals to a closed contour for $t < 0$ ($t > 0$).

transforms are analytic in the upper half-plane.

The three cases in (3.85) can be collected into a single formula using the Heaviside function $\Theta(t)$ of Eq. (1.313):

$$G_{\omega}(t) = e^{-i\omega t} \bar{\Theta}(t). \quad (3.86)$$

The periodic Green function (3.84) can then be written as

$$G_{\omega}^{\text{p}}(t) = \sum_{n=-\infty}^{\infty} e^{-i\omega[t-(t_b-t_a)n]} \bar{\Theta}(t - (t_b - t_a)n). \quad (3.87)$$

Being periodic in $t_b - t_a$, its explicit evaluation can be restricted to the basic interval

$$t \in [0, t_b - t_a). \quad (3.88)$$

Inside the interval $(0, t_b - t_a)$, the sum can be performed as follows:

$$\begin{aligned} G_{\omega}^{\text{p}}(t) &= \sum_{n=-\infty}^0 e^{-i\omega[t-(t_b-t_a)n]} = \frac{e^{-i\omega t}}{1 - e^{-i\omega(t_b-t_a)}} \\ &= -i \frac{e^{-i\omega[t-(t_b-t_a)/2]}}{2 \sin[\omega(t_b - t_a)/2]}, \quad t \in (0, t_b - t_a). \end{aligned} \quad (3.89)$$

At the point $t = 0$, the initial term with $\bar{\Theta}(0)$ contributes only 1/2 so that

$$G_{\omega}^{\text{p}}(0) = G_{\omega}^{\text{p}}(0+) - \frac{1}{2}. \quad (3.90)$$

Outside the basic interval (3.88), the Green function is determined by its periodicity. For instance,

$$G_{\omega}^{\text{p}}(t) = -i \frac{e^{-i\omega[t+(t_b-t_a)/2]}}{2 \sin[\omega(t_b - t_a)/2]}, \quad t \in (-(t_b - t_a), 0). \quad (3.91)$$

Note that as t crosses the upper end of the interval $[0, t_b - t_a)$, the sum in (3.87) picks up an additional term (the term with $n = 1$). This causes a jump in $G_\omega^p(t)$ which enforces the periodicity. At the upper point $t = t_b - t_a$, there is again a reduction by $1/2$ so that $G_\omega^p(t_b - t_a)$ lies in the middle of the jump, just as the value $1/2$ lies in the middle of the jump of the Heaviside function $\bar{\Theta}(t)$.

The periodic Green function is of great importance in the quantum statistics of Bose particles (see Chapter 7). After a continuation of the time to imaginary values, $t \rightarrow -i\tau$, $t_b - t_a \rightarrow -i\hbar/k_B T$, it takes the form

$$G_{\omega,e}^p(\tau) = \frac{1}{1 - e^{-\hbar\omega/k_B T}} e^{-\omega\tau}, \quad \tau \in (0, \hbar\beta), \quad (3.92)$$

where the subscript e records the Euclidean character of the time. The prefactor is related to the average boson occupation number of a particle state of energy $\hbar\omega$, given by the *Bose-Einstein distribution function*

$$n_\omega^b = \frac{1}{e^{\hbar\omega/k_B T} - 1}. \quad (3.93)$$

In terms of it,

$$G_{\omega,e}^p(\tau) = (1 + n_\omega^b) e^{-\omega\tau}, \quad \tau \in (0, \hbar\beta). \quad (3.94)$$

The τ -behavior of the subtracted periodic Green function $G_{\omega,e}^{p'}(\tau) \equiv G_{\omega,e}^p(\tau) - 1/\hbar\beta\omega$ is shown in Fig. 3.2.

Figure 3.2 Subtracted periodic Green function $G_{\omega,e}^{p'} \equiv G_{\omega,e}^p(\tau) - 1/\hbar\beta\omega$ and antiperiodic Green function $G_{\omega,e}^a(\tau)$ for frequencies $\omega = (0, 5, 10)/\hbar\beta$ (with increasing dash length). The points show the values at the jumps of the three functions (with increasing point size) corresponding to the relation (3.90).

As a next step, we consider a Green function $G_{\omega_2}^p(t)$ associated with the second-order differential operator $-\partial_t^2 - \omega^2$,

$$G_{\omega_2}^p(t, t') = (-\partial_t^2 - \omega^2)^{-1} \delta(t - t'), \quad t - t' \in [t_a, t_b), \quad (3.95)$$

which satisfies the periodic boundary condition:

$$G_{\omega_2}^p(t, t') \equiv G_{\omega_2}^p(t - t') = G_{\omega_2}^p(t - t' + t_b - t_a). \quad (3.96)$$

Figure 3.3 Two poles in Fourier transform of Green function $G_{\omega^2}^{\text{p;a}}(t)$.

Just like $G_{\omega}^{\text{p}}(t, t')$, this periodic Green function depends only on the time difference $t - t'$. It obviously has the spectral representation

$$G_{\omega^2}^{\text{p}}(t) = \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} e^{-i\omega_m t} \frac{1}{\omega_m^2 - \omega^2}, \quad (3.97)$$

which makes sense as long as $t_b - t_a$ is not equal to an even multiple of π/ω . At infinite $t_b - t_a$, the sum becomes an integral over ω_m with singularities at $\pm\omega$ which must be avoided by an $i\eta$ -prescription, which adds a negative imaginary part to the frequency ω [compare the discussion after Eq. (2.168)]. This fixes also the continuation from small $t_b - t_a$ beyond the multiple values of π/ω . By decomposing

$$\frac{1}{\omega'^2 - \omega^2 + i\eta} = \frac{1}{2i\omega} \left(\frac{i}{\omega' - \omega + i\eta} - \frac{i}{\omega' + \omega - i\eta} \right), \quad (3.98)$$

the calculation of the Green function (3.97) can be reduced to the previous case. The positions of the two poles of (3.98) in the complex ω' -plane are illustrated in Fig. 3.3. In this way we find, using (3.89),

$$\begin{aligned} G_{\omega^2}^{\text{p}}(t) &= \frac{1}{2\omega i} [G_{\omega}^{\text{p}}(t) - G_{-\omega}^{\text{p}}(t)] \\ &= -\frac{1}{2\omega} \frac{\cos \omega[t - (t_b - t_a)/2]}{\sin[\omega(t_b - t_a)/2]}, \quad t \in [0, t_b - t_a]. \end{aligned} \quad (3.99)$$

In $G_{-\omega}^{\text{p}}(t)$ one must keep the small negative imaginary part attached to the frequency ω . For an infinite time interval $t_b - t_a$, this leads to a Green function $G_{\omega^2}^{\text{p}}(t - t')$: also

$$G_{-\omega}(t) = -e^{-i\omega t} \bar{\Theta}(-t). \quad (3.100)$$

The directional change in encircling the pole in the ω' -integral leads to the exchange $\bar{\Theta}(t) \rightarrow -\bar{\Theta}(-t)$.

Outside the basic interval $t \in [0, t_b - t_a)$, the function is determined by its periodicity. For $t \in [-(t_b - t_a), 0)$, we may simply replace t by $|t|$.

As a further step we consider another Green function $G_\omega^a(t, t')$. It fulfills the same first-order differential equation $i\partial_t - \omega$ as $G_\omega^p(t, t')$:

$$(i\partial_t - \omega)G_\omega^a(t, t') = i\delta(t - t'), \quad t - t' \in [0, t_b - t_a], \quad (3.101)$$

but in contrast to $G_\omega^p(t, t')$ it satisfies the antiperiodic boundary condition

$$G_\omega^a(t, t') \equiv G_\omega^a(t - t') = -G_\omega^a(t - t' + t_b - t_a). \quad (3.102)$$

As for periodic boundary conditions, the Green function $G_\omega^a(t, t')$ depends only on the time difference $t - t'$. In contrast to $G_\omega^p(t, t')$, however, $G_\omega^a(t, t')$ changes sign under a shift $t \rightarrow t + (t_b - t_a)$. The Fourier expansion of $G_\omega^a(t - t')$ is

$$G_\omega^a(t) = \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} e^{-i\omega_m^f t} \frac{i}{\omega_m^f - \omega}, \quad (3.103)$$

where the frequency sum covers the *odd* Matsubara-like frequencies

$$\omega_m^f = \frac{\pi(2m + 1)}{t_b - t_a}. \quad (3.104)$$

The superscript f stands for *fermionic* since these frequencies play an important role in the statistical mechanics of particles with Fermi statistics to be explained in Section 7.10 [see Eq. (7.414)].

The antiperiodic Green functions are obtained from a sum similar to (3.82), but modified by an additional phase factor $e^{i\pi n} = (-)^n$. When inserted into the Poisson summation formula (3.81), such a phase is seen to select the half-integer numbers in the integral instead of the integer ones:

$$\sum_{m=-\infty}^{\infty} f(m + 1/2) = \int_{-\infty}^{\infty} d\mu \sum_{n=-\infty}^{\infty} (-)^n e^{2\pi i \mu n} f(\mu). \quad (3.105)$$

Using this formula, we can expand

$$\begin{aligned} G_\omega^a(t) &= \sum_{n=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{d\omega'}{2\pi} (-)^n e^{-i\omega'[t-(t_b-t_a)n]} \frac{i}{\omega' - \omega + i\eta} \\ &= \sum_{n=-\infty}^{\infty} (-)^n G_\omega(t - (t_b - t_a)n), \end{aligned} \quad (3.106)$$

or, more explicitly,

$$G_\omega^a(t) = \sum_{n=-\infty}^{\infty} e^{-i\omega[t-(t_b-t_a)n]} (-)^n \bar{\Theta}(t - (t_b - t_a)n). \quad (3.107)$$

For $t \in [0, t_b - t_a]$, this gives

$$\begin{aligned} G_\omega^a(t) &= \sum_{n=-\infty}^0 e^{-i\omega[t-(t_b-t_a)n]} (-)^n = \frac{e^{i\omega t}}{1 + e^{-i\omega(t_b-t_a)}} \\ &= \frac{e^{-i\omega[t-(t_b-t_a)/2]}}{2 \cos[\omega(t_b - t_a)/2]}, \quad t \in [0, t_b - t_a]. \end{aligned} \quad (3.108)$$

Outside the interval $t \in [0, t_b - t_a]$, the function is defined by its antiperiodicity. The τ -behavior of the antiperiodic Green function $G_{\omega,e}^a(\tau)$ is also shown in Fig. 3.2.

In the limit $\omega \rightarrow 0$, the right-hand side of (3.108) is equal to $1/2$, and the antiperiodicity implies that

$$G_0^a(t) = \frac{1}{2} \epsilon(t), \quad t \in [-(t_b - t_a), (t_b - t_a)]. \quad (3.109)$$

Antiperiodic Green functions play an important role in the quantum statistics of Fermi particles. After analytically continuing t to the imaginary time $-i\tau$ with $t_b - t_a \rightarrow -i\hbar/k_B T$, the expression (3.108) takes the form

$$G_{\omega,e}^a(\tau) = \frac{1}{1 + e^{-\hbar\omega/k_B T}} e^{-\omega\tau}, \quad \tau \in [0, \hbar\beta). \quad (3.110)$$

The prefactor is related to the average Fermi occupation number of a state of energy $\hbar\omega$, given by the *Fermi-Dirac distribution function*

$$n_\omega^f = \frac{1}{e^{\hbar\omega/k_B T} + 1}. \quad (3.111)$$

In terms of it,

$$G_{\omega,e}^a(\tau) = (1 - n_\omega^f) e^{-\omega\tau}, \quad \tau \in [0, \hbar\beta). \quad (3.112)$$

With the help of $G_\omega^a(t)$, we form the antiperiodic analog of (3.97), (3.99), i.e., the antiperiodic Green function associated with the second-order differential operator $-\partial_t^2 - \omega^2$:

$$\begin{aligned} G_{\omega^2}^a(t) &= \frac{1}{t_b - t_a} \sum_{m=0}^{\infty} e^{-i\omega_m^f t} \frac{1}{\omega_m^{f2} - \omega^2} \\ &= \frac{1}{2\omega i} [G_\omega^a(t) - G_{-\omega}^a(t)] \\ &= -\frac{1}{2\omega} \frac{\sin \omega[t - (t_b - t_a)/2]}{\cos[\omega(t_b - t_a)/2]}, \quad t \in [0, t_b - t_a]. \end{aligned} \quad (3.113)$$

Outside the basic interval $t \in [0, t_b - t_a]$, the Green function is determined by its antiperiodicity. If, for example, $t \in [-(t_b - t_a), 0]$, one merely has to replace t by $|t|$.

Note that the Matsubara sums

$$G_{\omega^2,e}^p(0) = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^2 + \omega^2}, \quad G_{\omega,e}^p(0) = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^{f2} + \omega^2}, \quad (3.114)$$

can also be calculated from the combinations of the simple Green functions (3.79) and (3.103):

$$\frac{1}{2\omega} [G_{\omega,e}^p(\eta) + G_{\omega,e}^p(-\eta)] = \frac{1}{2\omega} [G_{\omega,e}^p(\eta) + G_{\omega,e}^p(\hbar\beta - \eta)] = \frac{1}{2\omega} (1 + n_\omega^b) (1 + e^{-\beta\omega})$$

$$= \frac{1}{2\omega} \coth \frac{\hbar\omega\beta}{2}, \quad (3.115)$$

$$\begin{aligned} \frac{1}{2\omega} [G_{\omega,e}^a(\eta) + G_{\omega,e}^a(-\eta)] &= \frac{1}{2\omega} [G_{\omega,e}^a(\eta) - G_{\omega,e}^a(\hbar\beta - \eta)] = \frac{1}{2\omega} (1 - n_\omega^f) (1 - e^{-\beta\omega}) \\ &= \frac{1}{2\omega} \tanh \frac{\hbar\omega\beta}{2}, \end{aligned} \quad (3.116)$$

where η is an infinitesimal positive number needed to specify on which side of the jump the Green functions $G_{\omega,e}^{p,a}(\tau)$ at $\tau = 0$ have to be evaluated (see Fig. 3.2).

3.3.2 Time-Dependent Frequency

The above results (3.89) and (3.108) for the periodic and antiperiodic Green functions of the first-order differential operator $(i\partial_t - \omega)$ can easily be found also for arbitrary time-dependent frequencies $\Omega(t)$, thus solving (3.75). We shall look for the retarded version which vanishes for $t < t'$. This property is guaranteed by the ansatz containing the Heaviside function (1.313):

$$G_\Omega(t, t') = \bar{\Theta}(t - t')g(t, t'). \quad (3.117)$$

Using the property (1.307) of the Heaviside function, that its time derivative yields the δ -function, and normalizing $g(t, t')$ to be equal to 1, we see that $g(t, t')$ must solve the homogenous differential equation

$$[i\partial_t - \Omega(t)]g(t, t') = 0. \quad (3.118)$$

The solution is

$$g(t, t') = K(t')e^{-i\int_c^t dt'' \Omega(t'')}. \quad (3.119)$$

The condition $g(t, t) = 1$ fixes $K(t) = e^{i\int_c^t dt'' \Omega(t'')}$, so that we obtain

$$G_\Omega(t, t') = \bar{\Theta}(t - t')e^{-i\int_{t'}^t dt'' \Omega(t'')}. \quad (3.120)$$

The most general Green function is a sum of this and an arbitrary solution of the homogeneous equation (3.118):

$$G_\Omega(t, t') = [\bar{\Theta}(t - t') + C(t')]e^{-i\int_{t'}^t dt'' \Omega(t'')}. \quad (3.121)$$

For a periodic frequency $\Omega(t)$ we impose periodic boundary conditions upon the Green function, setting $G_\Omega(t_a, t') = G_\Omega(t_b, t')$. This is ensured if for $t_b > t > t' > t_a$:

$$C(t')e^{-i\int_{t'}^{t_a} dt'' \Omega(t'')} = [1 + C(t')]e^{-i\int_{t'}^{t_b} dt'' \Omega(t'')}. \quad (3.122)$$

This equation is solved by a t' -independent $C(t')$:

$$C = n_\Omega^p \equiv \frac{1}{e^{i\int_{t_a}^{t_b} dt'' \Omega(t'')} - 1}. \quad (3.123)$$

Hence we obtain the periodic Green function

$$G_{\Omega}^p(t, t') = [\bar{\Theta}(t - t') + n_{\Omega}^p] e^{-i \int_{t'}^t dt'' \Omega(t'')}. \quad (3.124)$$

For antiperiodic boundary conditions we obtain the same equation with n_{Ω}^p replaced by $-n_{\Omega}^a$ where

$$n_{\Omega}^a \equiv \frac{1}{e^{i \int_{t_a}^{t_b} dt \Omega(t)} + 1}. \quad (3.125)$$

Note that a sign change in the time derivative of the first-order differential equation (3.75) to

$$[-i\partial_t - \Omega(t)] G_{\Omega}(t, t') = i\delta(t - t') \quad (3.126)$$

has the effect of interchanging in the time variable t and t' of the Green function Eq. (3.120).

If the frequency $\Omega(t)$ is a matrix, all exponentials have to be replaced by time-ordered exponentials [recall (1.252)]

$$e^{i \int_{t_a}^{t_b} dt \Omega(t)} \rightarrow \hat{T} e^{i \int_{t_a}^{t_b} dt \Omega(t)}. \quad (3.127)$$

As remarked in Subsection 2.15.4, this integral cannot, in general, be calculated explicitly. A simple formula is obtained only if the matrix $\Omega(t)$ varies only little around a fixed matrix Ω_0 .

For imaginary times $\tau = it$ we generalize the results (3.92) and (3.110) for the periodic and antiperiodic imaginary-time Green functions of the first-order differential equation (3.76) to time-dependent periodic frequencies $\Omega(\tau)$. Here the Green function (3.120) becomes

$$G_{\Omega}(\tau, \tau') = \bar{\Theta}(\tau - \tau') e^{-\int_{\tau'}^{\tau} d\tau'' \Omega(\tau'')}, \quad (3.128)$$

and the periodic Green function (3.124):

$$G_{\Omega}(\tau, \tau') = [\bar{\Theta}(\tau - \tau') + n^b] e^{-\int_{\tau'}^{\tau} d\tau'' \Omega(\tau'')}, \quad (3.129)$$

where

$$n^b \equiv \frac{1}{e^{\int_0^{\hbar\beta} d\tau'' \Omega(\tau'')} - 1} \quad (3.130)$$

is the generalization of the Bose distribution function in Eq. (3.93). For antiperiodic boundary conditions we obtain the same equation, except that the generalized Bose distribution function is replaced by the negative of the generalized Fermi distribution function in Eq. (3.111):

$$n^f \equiv \frac{1}{e^{\int_0^{\hbar\beta} d\tau'' \Omega(\tau'')} + 1}. \quad (3.131)$$

For the opposite sign of the time derivative in (3.128), the arguments τ and τ' are interchanged.

From the Green functions (3.124) or (3.128) we may find directly the trace of the logarithm of the operators $[-i\partial_t + \Omega(t)]$ or $[\partial_\tau + \Omega(\tau)]$. At imaginary time, we multiply $\Omega(\tau)$ with a strength parameter g , and use the formula

$$\text{Tr} \log [\partial_\tau + g\Omega(\tau)] = \int_0^g dg' G_{g'\Omega}(\tau, \tau). \quad (3.132)$$

Inserting on the right-hand side of Eq. (3.129), we find for $g = 1$:

$$\begin{aligned} \text{Tr} \log [\partial_\tau + \Omega(\tau)] &= \log \left\{ 2 \sinh \left[\frac{1}{2} \int_0^{\hbar\beta} d\tau'' \Omega(\tau'') \right] \right\} \\ &= \frac{1}{2} \int_0^{\hbar\beta} d\tau'' \Omega(\tau'') + \log \left[1 - e^{-\int_0^{\hbar\beta} d\tau'' \Omega(\tau'')} \right], \end{aligned} \quad (3.133)$$

which reduces at low temperature to

$$\text{Tr} \log [\partial_\tau + \Omega(\tau)] = \frac{1}{2} \int_0^{\hbar\beta} d\tau'' \Omega(\tau''). \quad (3.134)$$

The result is the same for the opposite sign of the time derivative and the trace of the logarithm is sensitive only to $\bar{\Theta}(\tau - \tau')$ at $\tau = \tau'$, where it is equal to $1/2$.

As an exercise for dealing with distributions it is instructive to rederive this result in the following perturbative way. For a positive $\Omega(\tau)$, we introduce an infinitesimal positive quantity η and decompose

$$\begin{aligned} \text{Tr} \log [\pm\partial_\tau + \Omega(\tau)] &= \text{Tr} \log [\pm\partial_\tau + \eta] + \text{Tr} \log \left[1 + (\pm\partial_\tau + \eta)^{-1} \Omega(\tau) \right] \\ &= \text{Tr} \log [\pm\partial_\tau + \eta] + \text{Tr} \log \left[1 + (\pm\partial_\tau + \eta)^{-1} \Omega(\tau) \right]. \end{aligned} \quad (3.135)$$

The first term $\text{Tr} \log [\pm\partial_\tau + \eta] = \text{Tr} \log [\pm\partial_\tau + \eta] = \int_{-\infty}^{\infty} d\omega \log \omega$ vanishes since $\int_{-\infty}^{\infty} d\omega \log \omega = 0$ in dimensional regularization by Veltman's rule [see (2.508)]. Using the Green functions

$$[\pm\partial_\tau + \eta]^{-1}(\tau, \tau') = \begin{cases} \bar{\Theta}(\tau - \tau') \\ \bar{\Theta}(\tau' - \tau) \end{cases}, \quad (3.136)$$

the second term can be expanded in a Taylor series

$$\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \int d\tau_1 \cdots d\tau_n \Omega(\tau_1) \bar{\Theta}(\tau_1 - \tau_2) \Omega(\tau_2) \bar{\Theta}(\tau_2 - \tau_3) \cdots \Omega(\tau_n) \bar{\Theta}(\tau_n - \tau_1). \quad (3.137)$$

For the lower sign of $\pm\partial_\tau$, the Heaviside functions have reversed arguments $\tau_2 - \tau_1, \tau_3 - \tau_2, \dots, \tau_1 - \tau_n$. The integrals over a cyclic product of Heaviside functions in (3.137) are zero since the arguments τ_1, \dots, τ_n are time-ordered which makes the argument of the last factor $\bar{\Theta}(\tau_n - \tau_1)$ [or $\bar{\Theta}(\tau_1 - \tau_n)$] negative and thus $\bar{\Theta}(\tau_n - \tau_1) = 0$ [or $\bar{\Theta}(\tau_1 - \tau_n)$]. Only the first term survives yielding

$$\int d\tau_1 \Omega(\tau_1) \bar{\Theta}(\tau_1 - \tau_1) = \frac{1}{2} \int d\tau \Omega(\tau), \quad (3.138)$$

such that we re-obtain the result (3.134).

This expansion (3.133) can easily be generalized to an arbitrary matrix $\Omega(\tau)$ or a time-dependent operator, $\hat{H}(\tau)$. Since $\hat{H}(\tau)$ and $\hat{H}(\tau')$ do not necessarily commute, the generalization is

$$\text{Tr} \log[\hbar \partial_\tau + \hat{H}(\tau)] = \frac{1}{2\hbar} \text{Tr} \left[\int_0^{\hbar\beta} d\tau \hat{H}(\tau) \right] - \sum_{n=1}^{\infty} \frac{1}{n} \text{Tr} \left[\hat{T} e^{-n \int_0^{\hbar\beta} d\tau'' \hat{H}(\tau'')/\hbar} \right], \quad (3.139)$$

where \hat{T} is the time ordering operator (1.241). Each term in the sum contains a power of the time evolution operator (1.255).

3.4 Summing Spectral Representation of Green Function

After these preparations we are ready to perform the spectral sum (3.70) for the Green function of the differential equation of second order with Dirichlet boundary conditions. Setting $t_2 \equiv t_b - t$, $t_1 \equiv t' - t_a$, we rewrite (3.70) as

$$\begin{aligned} G_{\omega^2}(t, t') &= \frac{2}{t_b - t_a} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{(2i)^2} \frac{(e^{i\nu_n t_2} - e^{-i\nu_n t_2})(e^{i\nu_n t_1} - e^{-i\nu_n t_1})}{\nu_n^2 - \omega^2} \\ &= \frac{1}{2} \frac{1}{t_b - t_a} \sum_{n=1}^{\infty} (-1)^n \frac{[(e^{-i\nu_n(t_2+t_1)} - e^{-i\nu_n(t_2-t_1)}) + \text{c.c.}]}{\nu_n^2 - \omega^2} \\ &= \frac{1}{2} \frac{1}{t_b - t_a} \sum_{n=-\infty}^{\infty} (-1)^n \frac{e^{-i\nu_n(t_2+t_1)} - e^{-i\nu_n(t_2-t_1)}}{\nu_n^2 - \omega^2}. \end{aligned} \quad (3.140)$$

We now separate even and odd frequencies ν_n and write these as bosonic and fermionic Matsubara frequencies $\omega_m = \nu_{2m}$ and $\omega_m^f = \nu_{2m+1}$, respectively, recalling the definitions (3.80) and (3.104). In this way we obtain

$$\begin{aligned} G_{\omega^2}(t, t') &= \frac{1}{2} \left\{ \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} \frac{e^{-i\omega_m(t_2+t_1)}}{\omega_m^2 - \omega^2} - \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} \frac{e^{-i\omega_m^f(t_2+t_1)}}{\omega_m^{f2} - \omega^2} \right. \\ &\quad \left. - \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} \frac{e^{-i\omega_m(t_2-t_1)}}{\omega_m^2 - \omega^2} + \frac{1}{t_b - t_a} \sum_{m=-\infty}^{\infty} \frac{e^{-i\omega_m^f(t_2-t_1)}}{\omega_m^{f2} - \omega^2} \right\}. \end{aligned} \quad (3.141)$$

Inserting on the right-hand side the periodic and antiperiodic Green functions (3.99) and (3.108), we obtain the decomposition

$$G_{\omega^2}(t, t') = \frac{1}{2} [G_\omega^p(t_2 + t_1) - G_\omega^a(t_2 + t_1) - G_\omega^p(t_2 - t_1) + G_\omega^a(t_2 - t_1)]. \quad (3.142)$$

Using (3.99) and (3.113) we find that

$$G_\omega^p(t_2 + t_1) - G_\omega^p(t_2 - t_1) = \frac{\sin \omega[t_2 - (t_b - t_a)/2] \sin \omega t_1}{\omega \sin[\omega(t_b - t_a)/2]}, \quad (3.143)$$

$$G_\omega^a(t_2 + t_1) - G_\omega^a(t_2 - t_1) = -\frac{\cos \omega[t_2 - (t_b - t_a)/2] \sin \omega t_1}{\omega \cos[\omega(t_b - t_a)/2]}, \quad (3.144)$$

such that (3.142) becomes

$$G_{\omega^2}(t, t') = \frac{1}{\omega \sin \omega(t_b - t_a)} \sin \omega t_2 \sin \omega t_1, \quad (3.145)$$

in agreement with the earlier result (3.36).

An important limiting case is

$$t_a \rightarrow -\infty, \quad t_b \rightarrow \infty. \quad (3.146)$$

Then the boundary conditions become irrelevant and the Green function reduces to

$$G_{\omega^2}(t, t') = -\frac{i}{2\omega} e^{-i\omega|t-t'|}, \quad (3.147)$$

which obviously satisfies the second-order differential equation

$$(-\partial_t^2 - \omega^2)G_{\omega^2}(t, t') = \delta(t - t'). \quad (3.148)$$

The periodic and antiperiodic Green functions $G_{\omega^2}^p(t, t')$ and $G_{\omega^2}^a(t, t')$ at finite $t_b - t_a$ in Eqs. (3.99) and (3.113) are obtained from $G_{\omega^2}(t, t')$ by summing over all periodic repetitions [compare (3.106)]

$$\begin{aligned} G_{\omega^2}^p(t, t') &= \sum_{n=-\infty}^{\infty} G(t + n(t_b - t_a), t'), \\ G_{\omega^2}^a(t, t') &= \sum_{n=-\infty}^{\infty} (-1)^n G_{\omega^2}(t + n(t_b - t_a), t'). \end{aligned} \quad (3.149)$$

For completeness let us also sum the spectral representation with the normalized wave functions [compare (3.98)–(3.69)]

$$x_0(t) = \sqrt{\frac{1}{t_b - t_a}}, \quad x_n(t) = \sqrt{\frac{2}{t_b - t_a}} \cos \nu_n(t - t_a), \quad (3.150)$$

which reads:

$$G_{\omega^2}^N(t, t') = \frac{2}{t_b - t_a} \left[-\frac{1}{2\omega^2} + \sum_{n=1}^{\infty} \frac{\cos \nu_n(t - t_a) \cos \nu_n(t' - t_a)}{\nu_n^2 - \omega^2} \right]. \quad (3.151)$$

It satisfies the *Neumann boundary conditions*

$$\partial_t G_{\omega^2}^N(t, t') \Big|_{t=t_b} = 0, \quad \partial_{t'} G_{\omega^2}^N(t, t') \Big|_{t'=t_a} = 0. \quad (3.152)$$

The spectral representation (3.151) can be summed by a decomposition (3.140), if that the lowest line has a plus sign between the exponentials, and (3.142) becomes

$$G_{\omega^2}^N(t, t') = \frac{1}{2} [G_{\omega^2}^p(t_2 + t_1) - G_{\omega^2}^a(t_2 + t_1) + G_{\omega^2}^p(t_2 - t_1) - G_{\omega^2}^a(t_2 - t_1)]. \quad (3.153)$$

Using now (3.99) and (3.113) we find that

$$G_\omega^p(t_2 + t_1) + G_\omega^p(t_2 - t_1) = -\frac{\cos \omega[t_2 - (t_b - t_a)/2] \cos \omega t_1}{\omega \sin[\omega(t_b - t_a)/2]}, \quad (3.154)$$

$$G_\omega^a(t_2 + t_1) + G_\omega^a(t_2 - t_1) = -\frac{\sin \omega[t_2 - (t_b - t_a)/2] \cos \omega t_1}{\omega \cos[\omega(t_b - t_a)/2]}, \quad (3.155)$$

and we obtain instead of (3.145):

$$G_{\omega^2}^N(t, t') = -\frac{1}{\omega \sin \omega(t_b - t_a)} \cos \omega(t_b - t_>) \cos \omega(t_< - t_a), \quad (3.156)$$

which has the small- ω expansion

$$G_{\omega^2}^N(t, t') \underset{\omega^2 \approx 0}{\approx} -\frac{1}{(t_b - t_a)\omega^2} + \frac{t_b - t_a}{3} - \frac{1}{2}|t - t'| - \frac{1}{2}(t + t') + \frac{1}{2(t_b - t_a)}(t^2 + t'^2). \quad (3.157)$$

3.5 Wronski Construction for Periodic and Antiperiodic Green Functions

The Wronski construction in Subsection 3.2.1 of Green functions with time-dependent frequency $\Omega(t)$ satisfying the differential equation (3.27)

$$[-\partial_t^2 - \Omega^2(t)]G_{\Omega^2}(t, t') = \delta(t - t') \quad (3.158)$$

can easily be carried over to the Green functions $G_{\Omega^2}^{p,a}(t, t')$ with periodic and antiperiodic boundary conditions. As in Eq. (3.53) we decompose

$$G_{\Omega^2}^{p,a}(t, t') = \bar{\Theta}(t - t')\Delta(t, t') + a(t')\xi(t) + b(t')\eta(t), \quad (3.159)$$

with independent solutions of the homogenous equations $\xi(t)$ and $\eta(t)$, and insert this into (3.27), where $\delta^{p,a}(t - t')$ is the periodic version of the δ -function

$$\delta^{p,a}(t - t') \equiv \sum_{n=-\infty}^{\infty} \delta(t - t' - n\hbar\beta) \left\{ \begin{array}{l} 1 \\ (-1)^n \end{array} \right\}, \quad (3.160)$$

and $\Omega(t)$ is assumed to be periodic or antiperiodic in $t_b - t_a$. This yields again for $\Delta(t, t')$ the homogeneous initial-value problem (3.46), (3.45),

$$[-\partial_t^2 - \Omega^2(t)]\Delta(t, t') = 0; \quad \Delta(t, t) = 0, \quad \partial_t \Delta(t, t')|_{t'=t} = -1. \quad (3.161)$$

The periodic boundary conditions lead to the system of equations

$$\begin{aligned} a(t)[\xi(t_b) \mp \xi(t_a)] + b(t)[\eta(t_b) \mp \eta(t_a)] &= -\Delta(t_b, t), \\ a(t)[\dot{\xi}(t_b) \mp \dot{\xi}(t_a)] + b(t)[\dot{\eta}(t_b) \mp \dot{\eta}(t_a)] &= -\partial_t \Delta(t_b, t). \end{aligned} \quad (3.162)$$

Defining now the constant 2×2 -matrices

$$\bar{\Lambda}^{\text{p,a}}(t_a, t_b) = \begin{pmatrix} \xi(t_b) \mp \xi(t_a) & \eta(t_b) \mp \eta(t_a) \\ \dot{\xi}(t_b) \mp \dot{\xi}(t_a) & \dot{\eta}(t_b) \mp \dot{\eta}(t_a) \end{pmatrix}, \quad (3.163)$$

the condition analogous to (3.58),

$$\det \bar{\Lambda}^{\text{p,a}}(t_a, t_b) = W \bar{\Delta}^{\text{p,a}}(t_a, t_b) \neq 0, \quad (3.164)$$

with

$$\bar{\Delta}^{\text{p,a}}(t_a, t_b) = 2 \pm \partial_t \Delta(t_a, t_b) \pm \partial_t \Delta(t_b, t_a), \quad (3.165)$$

enables us to obtain the unique solution to Eqs. (3.162). After some algebra using the identities (3.51) and (3.52), the expression (3.159) for Green functions with periodic and antiperiodic boundary conditions can be cast into the form

$$G_{\Omega^2}^{\text{p,a}}(t, t') = G_{\Omega^2}(t, t') \mp \frac{[\Delta(t, t_a) \pm \Delta(t_b, t)][\Delta(t', t_a) \pm \Delta(t_b, t')]}{\bar{\Delta}^{\text{p,a}}(t_a, t_b) \Delta(t_a, t_b)}, \quad (3.166)$$

where $G_{\Omega^2}(t, t')$ is the Green function (3.59) with Dirichlet boundary conditions. As in (3.59) we may replace the functions on the right-hand side by the solutions $D_a(t)$ and $D_b(t)$ defined in Eqs. (2.228) and (2.229) with the help of (3.60).

The right-hand side of (3.166) is well-defined unless the operator $K(t) = -\partial_t^2 - \Omega^2(t)$ has a zero-mode, say $\eta(t)$, with periodic or antiperiodic boundary conditions $\eta(t_b) = \pm \eta(t_a)$, $\dot{\eta}(t_b) = \pm \dot{\eta}(t_a)$, which would make the determinant of the 2×2 -matrix $\bar{\Lambda}^{\text{p,a}}$ vanish.

3.6 Time Evolution Amplitude in Presence of Source Term

Given the Green function $G_{\omega^2}(t, t')$, we can write down an explicit expression for the time evolution amplitude. The quadratic source contribution to the fluctuation factor (3.21) is given explicitly by

$$\begin{aligned} \mathcal{A}_{j,\text{fl}} &= -\frac{1}{2M} \int_{t_a}^{t_b} dt \int_{t_a}^{t_b} dt' G_{\omega^2}(t, t') j(t) j(t') \\ &= -\frac{1}{M} \frac{1}{\omega \sin \omega(t_b - t_a)} \int_{t_a}^{t_b} dt \int_{t_a}^t dt' \sin \omega(t_b - t) \sin \omega(t' - t_a) j(t) j(t'). \end{aligned} \quad (3.167)$$

Altogether, the path integral in the presence of an external source $j(t)$ reads

$$(x_b t_b | x_a t_a)_\omega^j = \int \mathcal{D}x \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} (\dot{x}^2 - \omega^2 x^2) + jx \right] \right\} = e^{(i/\hbar) \mathcal{A}_{j,\text{cl}}} F_{\omega,j}(t_b, t_a), \quad (3.168)$$

with a total classical action

$$\begin{aligned} \mathcal{A}_{j,\text{cl}} &= \frac{1}{2} \frac{M\omega}{\sin \omega(t_b - t_a)} \left[(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a \right] \\ &+ \frac{1}{\sin \omega(t_b - t_a)} \int_{t_a}^{t_b} dt [x_a \sin \omega(t_b - t) + x_b \sin \omega(t - t_a)] j(t), \end{aligned} \quad (3.169)$$

and the fluctuation factor composed of (2.171) and a contribution from the current term $e^{i\mathcal{A}_{j,\text{fl}}/\hbar}$:

$$F_{\omega,j}(t_b, t_a) = F_{\omega}(t_b, t_a)e^{i\mathcal{A}_{j,\text{fl}}/\hbar} = \frac{1}{\sqrt{2\pi i\hbar/M}} \sqrt{\frac{\omega}{\sin \omega(t_b - t_a)}} \\ \times \exp \left\{ -\frac{i}{\hbar M \omega \sin \omega(t_b - t_a)} \int_{t_a}^{t_b} dt \int_{t_a}^t dt' \sin \omega(t_b - t) \sin \omega(t' - t_a) j(t) j(t') \right\}. \quad (3.170)$$

This expression is easily generalized to arbitrary time-dependent frequencies. Using the two independent solutions $D_a(t)$ and $D_b(t)$ of the homogenous differential equations (3.48), which were introduced in Eqs. (2.228) and (2.229), we find for the action (3.169) the general expression, composed of the harmonic action (2.268) and the current term $\int_{t_a}^{t_b} dt x_{\text{cl}}(t) j(t)$ with the classical solution (2.248):

$$\mathcal{A}_{j,\text{cl}} = \frac{M}{2D_a(t_b)} [x_b^2 \dot{D}_a(t_b) - x_a^2 \dot{D}_b(t_a) - 2x_b x_a] + \frac{1}{D_a(t_b)} \int_{t_a}^{t_b} dt [x_b D_a(t) + x_a D_b(t)] j(t). \quad (3.171)$$

The fluctuation factor is composed of the expression (2.263) for the current-free action, and the generalization of (3.167) with the Green function (3.61):

$$F_{\omega,j}(t_b, t_a) = F_{\omega}(t_b, t_a)e^{i\mathcal{A}_{j,\text{fl}}/\hbar} = \frac{1}{\sqrt{2\pi i\hbar/M}} \frac{1}{\sqrt{D_a(t_b)}} \exp \left\{ -\frac{i}{2\hbar M D_a(t_b)} \right. \\ \left. \times \int_{t_a}^{t_b} dt \int_{t_a}^t dt' j(t) [\bar{\Theta}(t - t') D_b(t) D_a(t') + \bar{\Theta}(t' - t) D_a(t) D_b(t')] j(t') \right\}. \quad (3.172)$$

For applications to statistical mechanics which becomes possible after an analytic continuation to imaginary times, it is useful to write (3.169) and (3.170) in another form. We introduce the Fourier transforms of the current

$$A(\omega) \equiv \frac{1}{M\omega} \int_{t_a}^{t_b} dt e^{-i\omega(t-t_a)} j(t), \quad (3.173)$$

$$B(\omega) \equiv \frac{1}{M\omega} \int_{t_a}^{t_b} dt e^{-i\omega(t_b-t)} j(t) = -e^{-i\omega(t_b-t_a)} A(-\omega), \quad (3.174)$$

and see that the classical source term in the exponent of (3.168) can be written as

$$\mathcal{A}_{j,\text{cl}} = -i \frac{M\omega}{\sin \omega(t_b - t_a)} \left\{ [x_b (e^{i\omega(t_b-t_a)} A - B)] + x_a (e^{i\omega(t_b-t_a)} B - A) \right\}. \quad (3.175)$$

The source contribution to the quadratic fluctuations in Eq. (3.167), on the other hand, can be rearranged to yield

$$\mathcal{A}_{j,\text{fl}} = \frac{i}{4M\omega} \int_{t_a}^{t_b} dt \int_{t_b}^{t_b} dt' e^{-i\omega|t-t'|} j(t) j(t') - \frac{M\omega}{2 \sin \omega(t_b - t_a)} [e^{i\omega(t_b-t_a)} (A^2 + B^2) - 2AB]. \quad (3.176)$$

This is seen as follows: We write the Green function between $j(t), j(t')$ in (3.168) as

$$\begin{aligned} & - \left[\sin \omega(t_b - t) \sin \omega(t' - t_a) \bar{\Theta}(t - t') + \sin \omega(t_b - t') \sin \omega(t - t_a) \bar{\Theta}(t' - t) \right] \\ & = \frac{1}{4} \left[\left(e^{i\omega(t_b - t_a)} e^{-i\omega(t - t')} + \text{c.c.} \right) - \left(e^{i\omega(t_b + t_a)} e^{-i\omega(t + t')} + \text{c.c.} \right) \right] \bar{\Theta}(t - t') \\ & \quad + \{t \leftrightarrow t'\}. \end{aligned} \quad (3.177)$$

Using $\bar{\Theta}(t - t') + \bar{\Theta}(t' - t) = 1$, this becomes

$$\begin{aligned} & \frac{1}{4} \left\{ - \left(e^{i\omega(t_b + t_a)} e^{-i\omega(t' + t)} + \text{c.c.} \right) \right. \\ & \quad + e^{i\omega(t_b - t_a)} \left(e^{-i\omega(t - t')} \bar{\Theta}(t - t') + e^{-i\omega(t' - t)} \bar{\Theta}(t' - t) \right) \\ & \quad \left. + e^{-i\omega(t_b - t_a)} \left[e^{i\omega(t - t')} (1 - \bar{\Theta}(t' - t)) + e^{i\omega(t' - t)} (1 - \bar{\Theta}(t - t')) \right] \right\}. \end{aligned} \quad (3.178)$$

A multiplication by $j(t), j(t')$ and an integration over the times t, t' yield

$$\begin{aligned} & \frac{1}{4} \left[- e^{i\omega(t_b - t_a)} 4M^2 \omega^2 (B^2 + A^2) \right. \\ & \quad \left. + \left(e^{i\omega(t_b - t_a)} - e^{-i\omega(t_b - t_a)} \right) \int_{t_a}^{t_b} dt \int_{t_b}^{t_b} dt' e^{-i\omega|t - t'|} j(t) j(t') + 4M^2 \omega^2 2AB \right], \end{aligned} \quad (3.179)$$

thus leading to (3.176).

If the source $j(t)$ is time-independent, the integrals in the current terms of the exponential of (3.169) and (3.170) can be done, yielding the j -dependent exponent

$$\begin{aligned} \frac{i}{\hbar} \mathcal{A}_j &= \frac{i}{\hbar} (\mathcal{A}_{j,\text{cl}} + \mathcal{A}_{j,\text{fl}}) = \frac{i}{\hbar} \left\{ \frac{1}{\omega \sin \omega(t_b - t_a)} [1 - \cos \omega(t_b - t_a)] (x_b + x_a) j \right. \\ & \quad \left. + \frac{1}{2M\omega^3} \left[\omega(t_b - t_a) + 2 \frac{\cos \omega(t_b - t_a) - 1}{\sin \omega(t_b - t_a)} \right] j^2 \right\}. \end{aligned} \quad (3.180)$$

Substituting $(1 - \cos \alpha)$ by $\sin \alpha \tan(\alpha/2)$, this yields the total source action becomes

$$\mathcal{A}_j = \frac{1}{\omega} \tan \frac{\omega(t_b - t_a)}{2} (x_b + x_a) j + \frac{1}{2M\omega^3} \left[\omega(t_b - t_a) - 2 \tan \frac{\omega(t_b - t_a)}{2} \right] j^2. \quad (3.181)$$

This result could also have been obtained more directly by taking the potential plus a constant-current term in the action

$$- \int_{t_a}^{t_b} dt \left(\frac{M}{2} \omega^2 x^2 - x j \right), \quad (3.182)$$

and by completing it quadratically to the form

$$- \int_{t_a}^{t_b} dt \frac{M}{2} \omega^2 \left(x - \frac{j}{M\omega^2} \right)^2 + \frac{t_b - t_a}{2M\omega^2} j^2. \quad (3.183)$$

This is a harmonic potential shifted in x by $-j/M\omega^2$. The time evolution amplitude can thus immediately be written down as

$$\begin{aligned} (x_b t_b | x_a t_a)_\omega^{j=\text{const}} &= \sqrt{\frac{M\omega}{2\pi i \hbar \sin \omega(t_b - t_a)}} \exp\left(\frac{i}{2\hbar} \frac{M\omega}{\sin \omega(t_b - t_a)}\right) \\ &\times \left\{ \left[\left(x_b - \frac{j}{M\omega^2}\right)^2 + \left(x_a - \frac{j}{M\omega^2}\right)^2 \right] \cos \omega(t_b - t_a) \right. \\ &\quad \left. - 2 \left(x_b - \frac{j}{M\omega^2}\right) \left(x_a - \frac{j}{M\omega^2}\right) \right\} + \frac{i}{\hbar} \frac{t_b - t_a}{2M\omega^2} j^2. \end{aligned} \quad (3.184)$$

In the free-particle limit $\omega \rightarrow 0$, the result becomes particularly simple:

$$\begin{aligned} (x_b t_b | x_a t_a)_0^{j=\text{const}} &= \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a)/M}} \exp\left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a}\right] \\ &\times \exp\left\{\frac{i}{\hbar} \left[\frac{1}{2}(x_b + x_a)(t_b - t_a)j - \frac{1}{24M}(t_b - t_a)^3 j^2\right]\right\}. \end{aligned} \quad (3.185)$$

As a cross check, we verify that the total exponent is equal to i/\hbar times the classical action

$$\mathcal{A}_{j,\text{cl}} = \int_{t_a}^{t_b} dt \left(\frac{M}{2} \dot{x}_{j,\text{cl}}^2 + j x_{j,\text{cl}} \right), \quad (3.186)$$

calculated for the classical orbit $x_{j,\text{cl}}(t)$ connecting x_a and x_b in the presence of the constant current j . This satisfies the Euler-Lagrange equation

$$\ddot{x}_{j,\text{cl}} = j/M, \quad (3.187)$$

which is solved by

$$x_{j,\text{cl}}(t) = x_a + \left[x_b - x_a - \frac{j}{2M}(t_b - t_a)^2 \right] \frac{t - t_a}{t_b - t_a} + \frac{j}{2M}(t - t_a)^2. \quad (3.188)$$

Inserting this into the action yields

$$\mathcal{A}_{j,\text{cl}} = \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} + \frac{1}{2}(x_b + x_a)(t_b - t_a)j - \frac{(t_b - t_a)^3 j^2}{24M}, \quad (3.189)$$

just as in the exponent of (3.185).

Let us remark that the calculation of the oscillator amplitude $(x_a t_b | x_a t)_\omega^j$ in (3.168) could have proceeded alternatively by using the orbital separation

$$x(t) = x_{j,\text{cl}}(t) + \delta x(t), \quad (3.190)$$

where $x_{j,\text{cl}}(t)$ satisfies the Euler-Lagrange equations with the time-dependent source term

$$\ddot{x}_{j,\text{cl}}(t) + \omega^2 x_{j,\text{cl}}(t) = j(t)/M, \quad (3.191)$$

rather than the orbital separation of Eq. (3.7),

$$x(t) = x_{\text{cl}}(t) + \delta x(t),$$

where $x_{\text{cl}}(t)$ satisfied the Euler-Lagrange equation with no source. For this *inhomogeneous* differential equation we would have found the following solution passing through x_a at $t = t_a$ and x_b at $t = t_b$:

$$x_{j,\text{cl}}(t) = x_a \frac{\sin \omega(t_b - t)}{\sin \omega(t_b - t_a)} + x_b \frac{\sin \omega(t - t_a)}{\sin \omega(t_b - t_a)} + \frac{1}{M} \int_{t_a}^{t_b} dt' G_{\omega^2}(t, t') j(t'). \quad (3.192)$$

The Green function $G_{\omega^2}(t, t')$ appears now at the classical level. The separation (3.190) in the total action would have had the advantage over (3.7) that the source causes no linear term in $\delta x(t)$. Thus, there would be no need for a quadratic completion; the classical action would be found from a pure surface term plus one half of the source part of the action

$$\begin{aligned} \mathcal{A}_{\text{cl}} &= \int_{t_a}^{t_b} dt \left[\frac{M}{2} (\dot{x}_{\text{cl},j}^2 - \omega^2 x_{j,\text{cl}}^2) + j x_{j,\text{cl}} \right] = \frac{M}{2} x_{j,\text{cl}} \dot{x}_{j,\text{cl}} \Big|_{t_a}^{t_b} \\ &+ \int_{t_a}^{t_b} dt \left[\frac{M}{2} x_{j,\text{cl}} \left(-\ddot{x}_{j,\text{cl}} - \omega^2 x_{j,\text{cl}} + \frac{j}{M} \right) \right] + \frac{1}{2} \int_{t_a}^{t_b} dt x_{j,\text{cl}} j \\ &= \frac{M}{2} (x_b \dot{x}_b - x_a \dot{x}_a) \Big|_{x=x_{j,\text{cl}}} + \frac{1}{2} \int_{t_a}^{t_b} dt x_{j,\text{cl}}(t) j(t). \end{aligned} \quad (3.193)$$

Inserting $x_{j,\text{cl}}$ from (3.192) and $G_{\omega^2}(t, t')$ from (3.36) leads once more to the exponent in (3.168). The fluctuating action quadratic in $\delta x(t)$ would have given the same fluctuation factor as in the $j = 0$ -case, i.e., the prefactor in (3.168) with no further j^2 (due to the absence of a quadratic completion).

3.7 Time Evolution Amplitude at Fixed Path Average

Another interesting quantity to be needed in Chapter 15 is the Fourier transform of the amplitude (3.184):

$$(x_b t_b | x_a t_a)_{\omega}^{x_0} = (t_b - t_a) \int_{-\infty}^{\infty} \frac{dj}{2\pi\hbar} e^{-ij(t_b - t_a)x_0/\hbar} (x_b t_b | x_a t_a)_{\omega}^j. \quad (3.194)$$

This is the amplitude for a particle to run from x_a to x_b along restricted paths whose temporal average $\bar{x} \equiv (t_b - t_a)^{-1} \int_{t_a}^{t_b} dt x(t)$ is held fixed at x_0 :

$$(x_b t_b | x_a t_a)_{\omega}^{x_0} = \int \mathcal{D}x \delta(x_0 - \bar{x}) \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}^2 - \omega^2 x^2) \right\}. \quad (3.195)$$

This property of the paths follows directly from the fact that the integral over the time-independent source j (3.194) produces a δ -function $\delta((t_b - t_a)x_0 - \int_{t_a}^{t_b} dt x(t))$. Restricted amplitudes of this type will turn out to have important applications later in Subsection 3.25.1 and in Chapters 5, 10, and 15.

The integral over j in (3.194) is done after a quadratic completion in $\mathcal{A}_j - j(t_b - t_a)x_0$ with \mathcal{A}_j of (3.181):

$$\mathcal{A}_j - j(t_b - t_a)x_0 = \frac{1}{2M\omega^3} \left[\omega(t_b - t_a) - 2 \tan \frac{\omega(t_b - t_a)}{2} \right] (j - j_0)^2 + \mathcal{A}^{x_0}, \quad (3.196)$$

with

$$j_0 = \frac{M\omega^2}{\omega(t_b - t_a) - 2 \tan \frac{\omega(t_b - t_a)}{2}} \left[\omega(t_b - t_a)x_0 - \tan \frac{\omega(t_b - t_a)}{2}(x_b + x_a) \right], \quad (3.197)$$

and

$$\mathcal{A}^{x_0} = -\frac{M\omega}{2 \left[\omega(t_b - t_a) - 2 \tan \frac{\omega(t_b - t_a)}{2} \right]} \left[\omega(t_b - t_a)x_0 - \tan \frac{\omega(t_b - t_a)}{2}(x_a + x_b) \right]^2. \quad (3.198)$$

With the completed quadratic exponent (3.196), the Gaussian integral over j in (3.194) can immediately be done, yielding

$$(x_b t_b | x_a t_a)_\omega^{x_0} = (x_b t_b | x_a t_a) \frac{t_b - t_a}{\sqrt{2\pi\hbar}} \sqrt{\frac{iM\omega^3}{\omega(t_b - t_a) - 2 \tan \frac{\omega(t_b - t_a)}{2}}} \exp\left(\frac{i}{\hbar} \mathcal{A}^{x_0}\right). \quad (3.199)$$

In the free-particle limit $\omega \rightarrow 0$, this reduces to

$$(x_b t_b | x_a t_a)_\omega^{x_0} = \frac{\sqrt{3}M}{\pi\hbar i(t_b - t_a)} \exp\left\{ \frac{Mi}{2\hbar(t_b - t_a)} \left[(x_b - x_a)^2 + 12 \left(x_0 - \frac{x_b + x_a}{2}\right)^2 \right] \right\}. \quad (3.200)$$

If we set $x_b = x_a$ in (3.199) and integrate over $x_b = x_a$, we find the quantum-mechanical version of the partition function at fixed x_0 :

$$Z_\omega^{x_0} = \frac{1}{\sqrt{2\pi\hbar(t_b - t_a)/Mi}} \frac{\omega(t_b - t_a)/2}{\sin[\omega(t_b - t_a)/2]} \exp\left[-\frac{i}{2\hbar}(t_b - t_a)M\omega^2 x_0^2\right]. \quad (3.201)$$

As a check we integrate this over x_0 and recover the correct Z_ω of Eq. (2.412).

We may also integrate over both ends independently to obtain the partition function

$$Z_\omega^{\text{open}, x_0} = \sqrt{\frac{\omega(t_b - t_a)}{\sin \omega(t_b - t_a)}} \exp\left[-\frac{i}{2\hbar}(t_b - t_a)M\omega^2 x_0^2\right]. \quad (3.202)$$

Integrating this over x_0 and going to imaginary times leads back to the partition function Z_ω^{open} of Eq. (2.413).

3.8 External Source in Quantum-Statistical Path Integral

In the last section we have found the quantum-mechanical time evolution amplitude in the presence of an external source term. Let us now do the same thing for the quantum-statistical case and calculate the path integral

$$(x_b \hbar\beta | x_a 0)_\omega^j = \int \mathcal{D}x(\tau) \exp\left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2}(\dot{x}^2 + \omega^2 x^2) - j(\tau)x(\tau) \right] \right\}. \quad (3.203)$$

This will be done in two ways.

3.8.1 Continuation of Real-Time Result

The desired result is obtained most easily by an analytic continuation of the quantum-mechanical results (3.23), (3.168) in the time difference $t_b - t_a$ to an imaginary time $-i\hbar(\tau_b - \tau_a) = -i\hbar\beta$. This gives immediately

$$(x_b \hbar\beta | x_a 0)_\omega^j = \sqrt{\frac{M}{2\pi\hbar^2\beta}} \sqrt{\frac{\omega\hbar\beta}{\sinh\omega\hbar\beta}} \exp\left\{-\frac{1}{\hbar}\mathcal{A}_e^{\text{ext}}[j]\right\}, \quad (3.204)$$

with the extended classical Euclidean oscillator action

$$\mathcal{A}_e^{\text{ext}}[j] = \mathcal{A}_e + \mathcal{A}_e^j = \mathcal{A}_e + \mathcal{A}_{1,e}^j + \mathcal{A}_{2,e}^j, \quad (3.205)$$

where \mathcal{A}_e is the Euclidean action

$$\mathcal{A}_e = \frac{M\omega}{2\sinh\beta\hbar\omega} \left[(x_b^2 + x_a^2) \cosh\omega\hbar\beta - 2x_b x_a \right], \quad (3.206)$$

while the linear and quadratic Euclidean source terms are

$$\mathcal{A}_{1,e}^j = -\frac{1}{\sinh\omega\hbar\beta} \int_{\tau_a}^{\tau_b} d\tau [x_a \sinh\omega(\hbar\beta - \tau) + x_b \sinh\omega\tau] j(\tau), \quad (3.207)$$

and

$$\mathcal{A}_{2,e}^j = -\frac{1}{M} \int_0^{\hbar\beta} d\tau \int_0^\tau d\tau' j(\tau) G_{\omega^2,e}(\tau, \tau') j(\tau'), \quad (3.208)$$

where $G_{\omega^2,e}(\tau, \tau')$ is the Euclidean version of the Green function (3.36) with Dirichlet boundary conditions:

$$\begin{aligned} G_{\omega^2,e}(\tau, \tau') &= \frac{\sinh\omega(\hbar\beta - \tau_>) \sinh\omega\tau_<}{\omega \sinh\omega\hbar\beta} \\ &= \frac{\cosh\omega(\hbar\beta - |\tau - \tau'|) - \cosh\omega(\hbar\beta - \tau - \tau')}{2\omega \sinh\omega\hbar\beta}, \end{aligned} \quad (3.209)$$

satisfying the differential equation

$$(-\partial_\tau^2 + \omega^2) G_{\omega^2,e}(\tau, \tau') = \delta(\tau - \tau'). \quad (3.210)$$

It is related to the real-time Green function (3.36) by

$$G_{\omega^2,e}(\tau, \tau') = i G_{\omega^2}(-i\tau, -i\tau'), \quad (3.211)$$

the overall factor i accounting for the replacement $\delta(t - t') \rightarrow i\delta(\tau - \tau')$ on the right-hand side of (3.148) in going to (3.210) when going from the real time t to the Euclidean time $-i\tau$. The symbols $\tau_>$ and $\tau_<$ in the first line (3.209) denote the larger and the smaller of the Euclidean times τ and τ' , respectively.

The source terms (3.207) and (3.208) can be rewritten as follows:

$$\mathcal{A}_{1,e}^j = -\frac{M\omega}{\sinh \omega \hbar \beta} \left\{ [x_b(e^{-\beta \hbar \omega} A_e - B_e)] x_a(e^{-\beta \hbar \omega} B_e - A_e) \right\}, \quad (3.212)$$

and

$$\begin{aligned} \mathcal{A}_{2,e}^j = & -\frac{1}{4M\omega} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' e^{-\omega|\tau-\tau'|} j(\tau)j(\tau') \\ & + \frac{M\omega}{2 \sinh \omega \hbar \beta} [e^{\beta \hbar \omega} (A_e^2 + B_e^2) - 2A_e B_e]. \end{aligned} \quad (3.213)$$

We have introduced the Euclidean versions of the functions $A(\omega)$ and $B(\omega)$ in Eqs. (3.173) and (3.174) as

$$A_e(\omega) \equiv iA(\omega)|_{t_b-t_a=-i\hbar\beta} = \frac{1}{M\omega} \int_0^{\hbar\beta} d\tau e^{-\omega\tau} j(\tau), \quad (3.214)$$

$$B_e(\omega) \equiv iB(\omega)|_{t_b-t_a=-i\hbar\beta} = \frac{1}{M\omega} \int_0^{\hbar\beta} d\tau e^{-\omega(\hbar\beta-\tau)} j(\tau) = -e^{-\beta \hbar \omega} A_e(-\omega). \quad (3.215)$$

From (3.204) we now calculate the quantum-statistical partition function. Setting $x_b = x_a = x$, the first term in the action (3.205) becomes

$$\mathcal{A}_e = \frac{M\omega}{\sinh \beta \hbar \omega} 2 \sinh^2(\omega \hbar \beta / 2) x^2. \quad (3.216)$$

If we ignore the second and third action terms in (3.205) and integrate (3.204) over x , we obtain, of course, the free partition function

$$Z_\omega = \frac{1}{2 \sinh(\beta \hbar \omega / 2)}. \quad (3.217)$$

In the presence of j , we perform a quadratic completion in x and obtain a source-dependent part of the action (3.205):

$$\mathcal{A}_e^j = \mathcal{A}_{\text{fl},e}^j + \mathcal{A}_{\text{r},e}^j, \quad (3.218)$$

where the additional term $\mathcal{A}_{\text{r},e}^j$ is the remainder left by a quadratic completion. It reads

$$\mathcal{A}_{\text{r},e}^j = -\frac{M\omega}{2 \sinh \omega \beta} e^{\beta \hbar \omega} (A_e + B_e)^2. \quad (3.219)$$

Combining this with $\mathcal{A}_{\text{fl},e}^j$ of (3.213) gives

$$\mathcal{A}_{\text{fl},e}^j + \mathcal{A}_{\text{r},e}^j = -\frac{1}{4M\omega} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' e^{-\omega|\tau-\tau'|} j(\tau)j(\tau') - \frac{M\omega}{\sinh(\beta \hbar \omega / 2)} e^{\beta \hbar \omega / 2} A_e B_e. \quad (3.220)$$

This can be rearranged to the total source term

$$\mathcal{A}_e^j = -\frac{1}{4M\omega} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \frac{\cosh \omega(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\beta\hbar\omega/2)} j(\tau)j(\tau'). \quad (3.221)$$

This is proved by rewriting the latter integrand as

$$\frac{1}{2 \sinh(\beta\hbar\omega/2)} \left\{ \left[e^{\omega(\tau-\tau')} e^{-\beta\hbar\omega/2} + (\omega \rightarrow -\omega) \right] \bar{\Theta}(\tau - \tau') \right. \\ \left. + \left[e^{\omega(\tau'-\tau)} e^{-\beta\hbar\omega/2} + (\omega \rightarrow -\omega) \right] \bar{\Theta}(\tau' - \tau) \right\} j(\tau)j(\tau').$$

In the second and fourth terms we replace $e^{\beta\hbar\omega/2}$ by $e^{-\beta\hbar\omega/2} + 2 \sinh(\beta\hbar\omega/2)$ and integrate over τ, τ' , with the result (3.220).

The expression between the currents in (3.221) is recognized as the Euclidean version of the periodic Green function $G_{\omega^2}^p(\tau)$ in (3.99):

$$G_{\omega^2,e}^p(\tau) \equiv iG_{\omega^2}^p(-i\tau)|_{t_b-t_a=-i\hbar\beta} \\ = \frac{1}{2\omega} \frac{\cosh \omega(\tau - \hbar\beta/2)}{\sinh(\beta\hbar\omega/2)}, \quad \tau \in [0, \hbar\beta]. \quad (3.222)$$

In terms of (3.221), the partition function of an oscillator in the presence of the source term is

$$Z_\omega[j] = Z_\omega \exp \left(-\frac{1}{\hbar} \mathcal{A}_e^j \right). \quad (3.223)$$

For completeness, let us also calculate the partition function of all paths with open ends in the presence of the source $j(t)$, thus generalizing the result (2.413). Integrating (3.204) over initial and final positions x_a and x_b we obtain

$$Z_\omega^{\text{open}}[j] = \sqrt{\frac{2\pi\hbar}{M\omega}} \frac{1}{\sqrt{\sinh[\omega(\tau_b - \tau_a)]}} e^{-(\mathcal{A}_{2,e}^j + \tilde{\mathcal{A}}_{2,e}^j)/\hbar}, \quad (3.224)$$

where

$$\tilde{\mathcal{A}}_{2,e}^j = -\frac{1}{M} \int_0^{\hbar\beta} d\tau \int_0^\tau d\tau' j(\tau) \tilde{G}_{\omega^2}(\tau, \tau') j(\tau'), \quad (3.225)$$

with

$$\tilde{G}_{\omega^2}(\tau, \tau') = \frac{1}{2\omega \sinh^3 \omega\hbar\beta} \left\{ \cosh \omega\hbar\beta [\sinh \omega(\hbar\beta - \tau) \sinh \omega(\hbar\beta - \tau') + \sinh \omega\tau \sinh \omega\tau'] \right. \\ \left. + \sinh \omega(\hbar\beta - \tau) \sinh \omega\tau' + \sinh \omega(\hbar\beta - \tau') \sinh \omega\tau \right\}. \quad (3.226)$$

By some trigonometric identities, this can be simplified to

$$\tilde{G}_{\omega^2}(\tau, \tau') = \frac{1}{\omega} \frac{\cosh \omega(\hbar\beta - \tau - \tau')}{\sinh \omega\hbar\beta}. \quad (3.227)$$

The first step is to rewrite the curly brackets in (3.226) as

$$\begin{aligned} & \sinh \omega \tau \left[\cosh \omega \hbar \beta \sinh \omega \tau' + \sinh \omega (\hbar \beta - \tau') \right] \\ & + \sinh \omega (\hbar \beta - \tau') \left[\cosh \omega \hbar \beta \sinh \omega (\hbar \beta - \tau) + \sinh \omega (\hbar \beta - ((\hbar \beta - \tau))) \right]. \end{aligned} \quad (3.228)$$

The first bracket is equal to $\sinh \beta \hbar \omega \cosh \omega \tau$, the second to $\sinh \beta \hbar \omega \cosh \omega (\hbar \beta - \tau')$, so that we arrive at

$$\sinh \omega \hbar \beta \left[\sinh \omega \tau \cosh \omega \tau' + \sinh \omega (\hbar \beta - \tau) \cosh \omega (\hbar \beta - \tau') \right]. \quad (3.229)$$

The bracket is now rewritten as

$$\frac{1}{2} \left[\sinh \omega (\tau + \tau') + \sinh \omega (\tau - \tau') + \sinh \omega (2\hbar \beta - \tau - \tau') + \sinh \omega (\tau' - \tau) \right], \quad (3.230)$$

which is equal to

$$\frac{1}{2} \left[\sinh \omega (\hbar \beta + \tau + \tau' - \hbar \beta) + \sinh \omega (\hbar \beta + \hbar \beta - \tau - \tau') \right], \quad (3.231)$$

and thus to

$$\frac{1}{2} \left[2 \sinh \omega \hbar \beta \cosh \omega (\hbar \beta - \tau - \tau') \right], \quad (3.232)$$

such that we arrive indeed at (3.227). The source action in the exponent in (3.224) is therefore:

$$(\mathcal{A}_{2,e}^j + \tilde{\mathcal{A}}_{2,e}^j) = -\frac{1}{M} \int_0^{\hbar \beta} d\tau \int_0^\tau d\tau' j(\tau) G_{\omega^2,e}^{\text{open}}(\tau, \tau') j(\tau'), \quad (3.233)$$

with (3.208)

$$\begin{aligned} G_{\omega^2,e}^{\text{open}}(\tau, \tau') &= \frac{\cosh \omega (\hbar \beta - |\tau - \tau'|) + \cosh \omega (\hbar \beta - \tau - \tau')}{2\omega \sinh \omega \hbar \beta} \\ &= \frac{\cosh \omega (\hbar \beta - \tau_>) \cosh \omega \tau_<}{\omega \sinh \omega \hbar \beta}. \end{aligned} \quad (3.234)$$

This Green function coincides precisely with the Euclidean version of Green function $G_{\omega^2}^{\text{N}}(t, t')$ in Eq. (3.151) using the relation (3.211). This coincidence should have been expected after having seen in Section 2.12 that the partition function of all paths with open ends can be calculated, up to a trivial factor $l_e(\hbar \beta)$ of Eq. (2.353), as a sum over all paths satisfying Neumann boundary conditions (2.451), which is calculated using the measure (2.454) for the Fourier components.

In the limit of small- ω , the Green function (3.234) reduces to

$$G_{\omega^2,e}^{\text{open}}(\tau, \tau') \underset{\omega^2 \approx 0}{\approx} \frac{1}{\beta \omega^2} + \frac{\beta}{3} - \frac{1}{2} |\tau - \tau'| - \frac{1}{2} (\tau + \tau') + \frac{1}{2\beta} (\tau^2 + \tau'^2), \quad (3.235)$$

which is the imaginary-time version of (3.157).

3.8.2 Calculation at Imaginary Time

Let us now see how the partition function with a source term is calculated directly in the imaginary-time formulation, where the periodic boundary condition is used from the outset. Thus we consider

$$Z_\omega[j] = \int \mathcal{D}x(\tau) e^{-\mathcal{A}_e[j]/\hbar}, \quad (3.236)$$

with the Euclidean action

$$\mathcal{A}_e[j] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) - j(\tau)x(\tau) \right]. \quad (3.237)$$

Since $x(\tau)$ satisfies the periodic boundary condition, we can perform a partial integration of the kinetic term without picking up a boundary term $x\dot{x}|_{t_a}^{t_b}$. The action becomes

$$\mathcal{A}_e[j] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} x(\tau)(-\partial_\tau^2 + \omega^2)x(\tau) - j(\tau)x(\tau) \right]. \quad (3.238)$$

Let $D_e(\tau, \tau')$ be the functional matrix

$$D_{\omega^2, e}(\tau, \tau') \equiv (-\partial_\tau^2 + \omega^2)\delta(\tau - \tau'), \quad \tau - \tau' \in [0, \hbar\beta]. \quad (3.239)$$

Its functional inverse is the Euclidean Green function,

$$G_{\omega^2, e}^p(\tau, \tau') = G_{\omega^2, e}^p(\tau - \tau') = D_{\omega^2, e}^{-1}(\tau, \tau') = (-\partial_\tau^2 + \omega^2)^{-1}\delta(\tau - \tau'), \quad (3.240)$$

with the periodic boundary condition.

Next we perform a quadratic completion by shifting the path:

$$x \rightarrow x' = x - \frac{1}{M} G_{\omega^2, e}^p j. \quad (3.241)$$

This brings the Euclidean action to the form

$$\mathcal{A}_e[j] = \int_0^{\hbar\beta} d\tau \frac{M}{2} x'(-\partial_\tau^2 + \omega^2)x' - \frac{1}{2M} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^p(\tau - \tau') j(\tau'). \quad (3.242)$$

The fluctuations over the periodic paths $x'(\tau)$ can now be integrated out and yield for $j(\tau) \equiv 0$

$$Z_\omega = \text{Det } D_{\omega^2, e}^{-1/2}. \quad (3.243)$$

As in Subsection 2.15.2, we find the functional determinant by rewriting the product of eigenvalues as

$$\text{Det } D_{\omega^2, e} = \prod_{m=-\infty}^{\infty} (\omega_m^2 + \omega^2) = \exp \left[\sum_{m=-\infty}^{\infty} \log(\omega_m^2 + \omega^2) \right], \quad (3.244)$$

and evaluating the sum in the exponent according to the rules of analytic regularization. This leads directly to the partition function of the harmonic oscillator as in Eq. (2.409):

$$Z_\omega = \frac{1}{2 \sinh(\beta \hbar \omega / 2)}. \quad (3.245)$$

The generating functional for $j(\tau) \neq 0$ is therefore

$$Z[j] = Z_\omega \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_e^j[j] \right\}, \quad (3.246)$$

with the source term:

$$\mathcal{A}_e^j[j] = -\frac{1}{2M} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^p(\tau - \tau') j(\tau'). \quad (3.247)$$

The Green function of imaginary time is calculated as follows. The eigenfunctions of the differential operator $-\partial_\tau^2$ are $e^{-i\omega_m \tau}$ with eigenvalues ω_m^2 , and the periodic boundary condition forces ω_m to be equal to the thermal Matsubara frequencies $\omega_m = 2\pi m / \hbar\beta$ with $m = 0, \pm 1, \pm 2, \dots$. Hence we have the Fourier expansion

$$G_{\omega^2, e}^p(\tau) = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^2 + \omega^2} e^{-i\omega_m \tau}. \quad (3.248)$$

In the zero-temperature limit, the Matsubara sum becomes an integral, yielding

$$G_{\omega^2, e}^p(\tau) \underset{T=0}{=} \int \frac{d\omega_m}{2\pi} \frac{1}{\omega_m^2 + \omega^2} e^{-i\omega_m \tau} = \frac{1}{2\omega} e^{-\omega|\tau|}. \quad (3.249)$$

The frequency sum in (3.248) may be written as such an integral over ω_m , provided the integrand contains an additional Poisson sum (3.81):

$$\sum_{\bar{m}=-\infty}^{\infty} \delta(m - \bar{m}) = \sum_{n=-\infty}^{\infty} e^{i2\pi n m} = \sum_{n=-\infty}^{\infty} e^{in\omega_m \hbar\beta}. \quad (3.250)$$

This implies that the finite-temperature Green function (3.248) is obtained from (3.249) by a periodic repetition:

$$\begin{aligned} G_{\omega^2, e}^p(\tau) &= \sum_{n=-\infty}^{\infty} \frac{1}{2\omega} e^{-\omega|\tau + n\hbar\beta|} \\ &= \frac{1}{2\omega} \frac{\cosh \omega(\tau - \hbar\beta/2)}{\sinh(\beta \hbar \omega / 2)}, \quad \tau \in [0, \hbar\beta]. \end{aligned} \quad (3.251)$$

A comparison with (3.97), (3.99) shows that $G_{\omega^2, e}^p(\tau)$ coincides with $G_{\omega^2}^p(t)$ at imaginary times, as it should.

Note that for small ω , the Green function has the expansion

$$G_{\omega^2, e}^p(\tau) = \frac{1}{\hbar\beta\omega^2} + \frac{\tau^2}{2\hbar\beta} - \frac{\tau}{2} + \frac{\hbar\beta}{12} + \dots \quad (3.252)$$

The first term diverges in the limit $\omega \rightarrow 0$. Comparison with the spectral representation (3.248) shows that it stems from the zero Matsubara frequency contribution to the sum. If this term is omitted, the subtracted Green function

$$G_{\omega^2,e}^{\text{P}'}(\tau) \equiv G_{\omega^2,e}^{\text{P}}(\tau) - \frac{1}{\hbar\beta\omega^2} \quad (3.253)$$

has a well-defined $\omega \rightarrow 0$ limit

$$G_{0,e}^{\text{P}'}(\tau) = \frac{1}{\hbar\beta} \sum_{m=\pm 1, \pm 2, \dots} \frac{1}{\omega_m^2} e^{-i\omega_m \tau} = \frac{\tau^2}{2\hbar\beta} - \frac{\tau}{2} + \frac{\hbar\beta}{12}, \quad (3.254)$$

the right-hand side being correct only for $\tau \in [0, \hbar\beta]$. Outside this interval it must be continued periodically. The subtracted Green function $G_{\omega^2,e}^{\text{P}'}(\tau)$ is plotted for different frequencies ω in Fig. 3.4.

Figure 3.4 Subtracted periodic Green function $G_{\omega^2,e}^{\text{P}'}(\tau) \equiv G_{\omega^2,e}^{\text{P}}(\tau) - 1/\hbar\beta\omega^2$ and antiperiodic Green function $G_{\omega^2,e}^{\text{a}}(\tau)$ for frequencies $\omega = (0, 5, 10)/\hbar\beta$ (with increasing dash length). Compare Fig. 3.2.

The limiting expression (3.254) can, incidentally, be derived using the methods developed in Subsection 2.15.6. We rewrite the sum as

$$\frac{1}{\hbar\beta} \sum_{m=\pm 1, \pm 2, \dots} \frac{(-1)^m}{\omega_m^2} e^{-i\omega_m(\tau - \hbar\beta/2)} \quad (3.255)$$

and expand

$$-\frac{2}{\hbar\beta} \left(\frac{\hbar\beta}{2\pi}\right)^2 \sum_{n=0,2,4,\dots} \frac{1}{n!} \left[-i\frac{2\pi}{\hbar\beta}(\tau - \hbar\beta/2)\right]^n \sum_{m=1}^{\infty} \frac{(-1)^{m-1}}{m^{2-n}}. \quad (3.256)$$

The sum over m on the right-hand side is Riemann's eta function¹

$$\eta(z) \equiv \sum_{m=1}^{\infty} \frac{(-1)^{m-1}}{m^z}, \quad (3.257)$$

¹M. Abramowitz and I. Stegun, op. cit., Formula 23.2.19.

which is related to the zeta function (2.521) by

$$\eta(z) = (1 - 2^{1-z})\zeta(z). \quad (3.258)$$

Since the zeta functions of negative integers are all zero [recall (2.587)], only the terms with $n = 0$ and 2 contribute in (3.256). Inserting

$$\eta(0) = -\zeta(0) = 1/2, \quad \eta(2) = \zeta(2)/2 = \pi^2/12, \quad (3.259)$$

we obtain

$$-\frac{2}{\hbar\beta} \left(\frac{\hbar\beta}{2\pi}\right)^2 \left[\frac{\pi^2}{12} - \frac{1}{4} \left(\frac{2\pi}{\hbar\beta}\right)^2 (\tau - \hbar\beta/2)^2 \right] = \frac{\tau^2}{2\hbar\beta} - \frac{\tau}{2} + \frac{\hbar\beta}{12}, \quad (3.260)$$

in agreement with (3.254).

It is worth remarking that the Green function (3.254) is directly proportional to the Bernoulli polynomial $B_2(z)$:

$$G_{0,e}^{p'}(\tau) = \frac{\hbar\beta}{2} B_2(\tau/\hbar\beta). \quad (3.261)$$

These polynomials are defined in terms of the Bernoulli numbers B_k as²

$$B_n(x) = \sum_{k=0}^n \binom{n}{k} B_k x^{n-k}. \quad (3.262)$$

They appear in the expansion of the generating function³

$$\frac{e^{zt}}{e^t - 1} = \sum_{n=0}^{\infty} B_n(z) \frac{t^{n-1}}{n!}, \quad (3.263)$$

and have the expansion

$$B_{2n}(z) = (-1)^{n-1} \frac{2(2n)!}{(2\pi)^{2n}} \sum_{k=0}^{\infty} \frac{\cos(2\pi kz)}{k^{2n}}, \quad (3.264)$$

with the special cases

$$B_1(z) = z - 1/2, \quad B_2(z) = z^2 - z + 1/6, \dots \quad (3.265)$$

By analogy with (3.251), the antiperiodic Green function can be obtained from an antiperiodic repetition

$$\begin{aligned} G_{\omega^2,e}^a(\tau) &= \sum_{n=-\infty}^{\infty} \frac{(-1)^n}{2\omega} e^{-\omega|\tau+n\hbar\beta|} \\ &= \frac{1}{2\omega} \frac{\sinh \omega(\tau - \hbar\beta/2)}{\cosh(\beta\hbar\omega/2)}, \quad \tau \in [0, \hbar\beta], \end{aligned} \quad (3.266)$$

²I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 9.620.

³ibid. Formula 9.621.

which is an analytic continuation of (3.113) to imaginary times. In contrast to (3.252), this has a finite $\omega \rightarrow 0$ limit

$$G_{\omega^2, e}^a(\tau) = \frac{\tau}{2} - \frac{\hbar\beta}{4}, \quad \tau \in [0, \hbar\beta]. \quad (3.267)$$

For a plot of the antiperiodic Green function for different frequencies ω see again Fig. 3.4.

The limiting expression (3.267) can again be derived using an expansion of the type (3.256). The spectral representation in terms of odd Matsubara frequencies (3.104)

$$G_{\omega^2, e}^a(\tau) \equiv \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^f} e^{-i\omega_m^f \tau} \quad (3.268)$$

is rewritten as

$$\frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^f} \cos(\omega_m^f \tau) = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{(-1)^m}{\omega_m^f} \sin[\omega_m^f (\tau - \hbar\beta/2)]. \quad (3.269)$$

Expanding the sin function yields

$$\frac{2}{\hbar\beta} \left(\frac{\hbar\beta}{2\pi} \right)^2 \sum_{n=1,3,5,\dots} \frac{(-1)^{(n-1)/2}}{n!} \left[\frac{2\pi}{\hbar\beta} (\tau - \hbar\beta/2) \right]^n \sum_{m=0}^{\infty} \frac{(-1)^m}{\left(m + \frac{1}{2}\right)^{2-n}}. \quad (3.270)$$

The sum over m at the end is 2^{2-n} times Riemann's beta function⁴ $\beta(2-n)$, which is defined as

$$\beta(z) \equiv \frac{1}{2^z} \sum_{m=0}^{\infty} \frac{(-1)^m}{\left(m + \frac{1}{2}\right)^z}, \quad (3.271)$$

and is related to Riemann's zeta function

$$\zeta(z, q) \equiv \sum_{m=0}^{\infty} \frac{1}{(m+q)^z}. \quad (3.272)$$

Indeed, we see immediately that

$$\sum_{m=0}^{\infty} \frac{(-1)^m}{(m+q)^z} = \zeta(z, q) - 2^{2-z} \zeta(z, (q+1)/2), \quad (3.273)$$

so that

$$\beta(z) \equiv \frac{1}{2^z} \left[\zeta(z, 1/2) - 2^{2-z} \zeta(z, 3/4) \right]. \quad (3.274)$$

Near $z = 1$, the function $\zeta(z, q)$ behaves like⁵

$$\zeta(z, q) = \frac{1}{z-1} - \psi(q) + \mathcal{O}(z-1), \quad (3.275)$$

⁴M. Abramowitz and I. Stegun, *op. cit.*, Formula 23.2.21.

⁵I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 9.533.2.

where $\psi(z)$ is the Digamma function (2.573). Thus we obtain in the limit $z \rightarrow 1$:

$$\beta(1) = \lim_{z \rightarrow 1} \frac{1}{2} [\zeta(z, 1/2) - 2^{1-z} \zeta(z, 3/4)] = \frac{1}{2} [-\psi(1/2) + \psi(3/4) + \log 2] = \frac{\pi}{4}. \quad (3.276)$$

The last result follows from the specific values [compare (2.575)]:

$$\psi(1/2) = -\gamma - 2 \log 2, \quad \psi(3/4) = -\gamma - 3 \log 2 + \frac{\pi}{2}. \quad (3.277)$$

For negative odd arguments, the beta function (3.271) vanishes, so that there are no further contributions. Inserting this into (3.270) the only surviving $n = 1$ -term yields once more (3.267).

Note that the relation (3.276) could also have been found directly from the expansion (2.574) of the Digamma function, which yields

$$\beta(1) = \frac{1}{4} [\psi(3/2) - \psi(1/4)], \quad (3.278)$$

and is equal to (3.276) due to $\psi(1/4) = -\gamma - 3 \log 2 - \pi/2$.

For currents $j(\tau)$, which are periodic in $\hbar\beta$, the source term (3.247) can also be written more simply:

$$\mathcal{A}_e^j[j] = -\frac{1}{4M\omega} \int_0^{\hbar\beta} d\tau \int_{-\infty}^{\infty} d\tau' e^{-\omega|\tau-\tau'|} j(\tau)j(\tau'). \quad (3.279)$$

This follows directly by rewriting (3.279), by analogy with (3.149), as a sum over all periodic repetitions of the zero-temperature Green function (3.249):

$$G_{\omega^2, e}^p(\tau) = \frac{1}{2\omega} \sum_{n=-\infty}^{\infty} e^{-\omega|\tau+n\hbar\beta|}. \quad (3.280)$$

When inserted into (3.247), the factors $e^{-n\beta\hbar\omega}$ can be removed by an irrelevant periodic temporal shift in the current $j(\tau') \rightarrow j(\tau' - n\hbar\beta)$ leading to (3.279).

For a time-dependent periodic or antiperiodic potential $\Omega(\tau)$, the Green function $G_{\omega^2, e}^{p, a}(\tau)$ solving the differential equation

$$[\partial_\tau^2 - \Omega^2(\tau)]G_{\omega^2, e}^{p, a}(\tau, \tau') = \delta^{p, a}(\tau - \tau'), \quad (3.281)$$

with the periodic or antiperiodic δ -function

$$\delta^{p, a}(\tau - \tau') = \sum_{n=-\infty}^{\infty} \delta(\tau - \tau' - n\hbar\beta) \left\{ \begin{array}{l} 1 \\ (-1)^n \end{array} \right\}, \quad (3.282)$$

can be expressed⁶ in terms of two arbitrary solutions $\xi(\tau)$ and $\eta(\tau)$ of the homogenous differential equation in the same way as the real-time Green functions in Section 3.5:

$$G_{\omega^2, e}^{p, a}(\tau, \tau') = G_{\omega^2, e}(\tau, \tau') \mp \frac{[\Delta(\tau, \tau_a) \pm \Delta(\tau_b, \tau)][\Delta(\tau', \tau_a) \pm \Delta(\tau_b, \tau')]}{\Delta^{p, a}(\tau_a, \tau_b)\Delta(\tau_a, \tau_b)}, \quad (3.283)$$

⁶See H. Kleinert and A. Chervyakov, Phys. Lett. A 245, 345 (1998) (quant-ph/9803016); J. Math. Phys. B 40, 6044 (1999) (physics/9712048).

where $G_{\omega^2,e}(\tau, \tau')$ is the imaginary-time Green function with Dirichlet boundary conditions corresponding to (3.209):

$$G_{\omega^2,e}(\tau, \tau') = \frac{\bar{\Theta}(\tau - \tau')\Delta(\tau_b, \tau)\Delta(\tau', \tau_a) + \bar{\Theta}(\tau - \tau')\Delta(\tau_b, \tau')\Delta(\tau, \tau_a)}{\Delta(\tau_a, \tau_b)}, \quad (3.284)$$

with

$$\Delta(\tau, \tau') = \frac{1}{W} [\xi(\tau)\eta(\tau') - \xi(\tau')\eta(\tau)], \quad W = \xi(\tau)\dot{\eta}(\tau) - \dot{\xi}(\tau)\eta(\tau), \quad (3.285)$$

and

$$\bar{\Delta}^{p,a}(\tau_a, \tau_b) = 2 \pm \partial_\tau \Delta(\tau_a, \tau_b) \pm \partial_\tau \Delta(\tau_b, \tau_a). \quad (3.286)$$

Let also write down the imaginary-time versions of the periodic or antiperiodic Green functions for time-dependent frequencies. Recall the expressions for constant frequency $G_\omega^p(t)$ and $G_\omega^a(t)$ of Eqs. (3.94) and (3.112) for $\tau \in (0, \hbar\beta)$:

$$\begin{aligned} G_{\omega,e}^p(\tau) &= \frac{1}{\hbar\beta} \sum_m e^{-i\omega_m \tau} \frac{-1}{i\omega_m - \omega} = e^{-\omega(\tau - \hbar\beta/2)} \frac{1}{2 \sinh(\beta\hbar\omega/2)} \\ &= (1 + n_\omega^b) e^{-\omega\tau}, \end{aligned} \quad (3.287)$$

and

$$\begin{aligned} G_{\omega,e}^a(\tau) &= \frac{1}{\hbar\beta} \sum_m e^{-i\omega_m^f \tau} \frac{-1}{i\omega_m^f - \omega} = e^{-\omega(\tau - \hbar\beta/2)} \frac{1}{2 \cosh(\beta\hbar\omega/2)} \\ &= (1 - n_\omega^f) e^{-\omega\tau}, \end{aligned} \quad (3.288)$$

the first sum extending over the even Matsubara frequencies, the second over the odd ones. The Bose and Fermi distribution functions $n_\omega^{b,f}$ were defined in Eqs. (3.93) and (3.111).

For $\tau < 0$, periodicity or antiperiodicity determine

$$G_{\omega,e}^{p,a}(\tau) = \pm G_{\omega,e}^{p,a}(\tau + \hbar\beta). \quad (3.289)$$

The generalization of these expressions to time-dependent periodic and antiperiodic frequencies $\Omega(\tau)$ satisfying the differential equations

$$[-\partial_\tau - \Omega(\tau)]G_{\Omega,e}^{p,a}(\tau, \tau') = \delta^{p,a}(\tau - \tau') \quad (3.290)$$

has for $\beta \rightarrow \infty$ the form

$$G_{\Omega,e}^{p,a}(\tau, \tau') = \bar{\Theta}(\tau - \tau') e^{-\int_0^\tau d\tau' \Omega(\tau')}. \quad (3.291)$$

Its periodic superposition yields for finite β a sum analogous to (3.280):

$$G_{\Omega,e}^{p,a}(\tau, \tau') = \sum_{n=0}^{\infty} e^{-\int_0^{\tau+n\hbar\beta} d\tau' \Omega(\tau')} \left\{ \begin{array}{c} 1 \\ (-1)^n \end{array} \right\}, \quad \hbar\beta > \tau > \tau' > 0, \quad (3.292)$$

which reduces to (3.287), (3.288) for a constant frequency $\Omega(\tau) \equiv \omega$.

3.9 Lattice Green Function

As in Chapter 2, it is easy to calculate the above results also on a sliced time axis. This is useful when it comes to comparing analytic results with Monte Carlo lattice simulations. We consider here only the Euclidean versions; the quantum-mechanical ones can be obtained by analytic continuation to real times.

The Green function $G_{\omega^2}(\tau, \tau')$ on an imaginary-time lattice with infinitely many lattice points of spacing ϵ reads [instead of the Euclidean version of (3.147)]:

$$G_{\omega^2}(\tau, \tau') = \frac{\epsilon}{2 \sinh \epsilon \tilde{\omega}_e} e^{-\tilde{\omega}_e |\tau - \tau'|} = \frac{1}{2\omega} \frac{1}{\cosh(\epsilon \tilde{\omega}_e / 2)} e^{-\tilde{\omega}_e |\tau - \tau'|}, \quad (3.293)$$

where $\tilde{\omega}_e$ is given, as in (2.406), by

$$\tilde{\omega}_e = \frac{2}{\epsilon} \operatorname{arsinh} \frac{\epsilon \omega}{2}. \quad (3.294) \quad \begin{array}{l} \text{ref(2.406)} \\ \text{lab(2.234)} \\ \text{est(2.277)} \end{array}$$

This is derived from the spectral representation

$$G_{\omega^2}(\tau, \tau') = G_{\omega^2}(\tau - \tau') = \int \frac{d\omega'}{2\pi} e^{-i\omega'(\tau - \tau')} \frac{\epsilon^2}{2(1 - \cos \epsilon \omega') + \epsilon^2 \omega'^2} \quad (3.295)$$

by rewriting it as

$$G_{\omega^2}(\tau, \tau') = \int_0^\infty ds \int \frac{d\omega'}{2\pi} e^{-i\omega' \epsilon n} e^{-s[2(1 - \cos \epsilon \omega') + \epsilon^2 \omega'^2]/\epsilon^2}, \quad (3.296)$$

with $n \equiv (\tau' - \tau)/\epsilon$, performing the ω' -integral which produces a Bessel function $I_{(\tau - \tau')/\epsilon}(2s/\epsilon^2)$, and subsequently the integral over s with the help of formula (2.475). The Green function (3.293) is defined only at discrete $\tau_n = n\hbar\beta/(N+1)$. If it is summed over all periodic repetitions $n \rightarrow n + k(N+1)$ with $k = 0, \pm 1, \pm 2, \dots$, one obtains the lattice analog of the periodic Green function (3.251):

$$\begin{aligned} G_e^p(\tau) &= \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{\epsilon^2}{2(1 - \cos \epsilon \omega_m) + \epsilon^2 \omega_m^2} e^{-i\omega_m \tau} \\ &= \frac{1}{2\omega} \frac{1}{\cosh(\epsilon \tilde{\omega}/2)} \frac{\cosh \tilde{\omega}(\tau - \hbar\beta/2)}{\sinh(\hbar \tilde{\omega} \beta/2)}, \quad \tau \in [0, \hbar\beta]. \end{aligned} \quad (3.297)$$

3.10 Correlation Functions, Generating Functional, and Wick Expansion

Equipped with the path integral of the harmonic oscillator in the presence of an external source it is easy to calculate the correlation functions of any number of position variables $x(\tau)$. We consider here only a system in thermal equilibrium and study the behavior at imaginary times. The real-time correlation functions can be discussed similarly. The precise relation between them will be worked out in Chapter 18.

In general, i.e., also for nonharmonic actions, the thermal correlation functions of n -variables $x(\tau)$ are defined as the functional averages

$$\begin{aligned} G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) &\equiv \langle x(\tau_1) x(\tau_2) \cdots x(\tau_n) \rangle \\ &\equiv Z^{-1} \int \mathcal{D}x x(\tau_1) x(\tau_2) \cdots x(\tau_n) \exp\left(-\frac{1}{\hbar} \mathcal{A}_e\right). \end{aligned} \quad (3.298)$$

They are also referred to as *n-point functions*. In operator quantum mechanics, the same quantities are obtained from the thermal expectation values of time-ordered products of Heisenberg position operators $\hat{x}_H(\tau)$:

$$G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) = Z^{-1} \text{Tr} \left\{ \hat{T}_\tau \left[\hat{x}_H(\tau_1) \hat{x}_H(\tau_2) \cdots \hat{x}_H(\tau_n) e^{-\hat{H}/k_B T} \right] \right\}, \quad (3.299)$$

where Z is the partition function

$$Z = e^{-F/k_B T} = \text{Tr}(e^{-\hat{H}/k_B T}) \quad (3.300)$$

and \hat{T}_τ is the time-ordering operator. Indeed, by slicing the imaginary-time evolution operator $e^{-\hat{H}\tau/\hbar}$ at discrete times in such a way that the times τ_i of the n position operators $x(\tau_i)$ are among them, we find that $G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n)$ has precisely the path integral representation (3.298).

By definition, the path integral with the product of $x(\tau_i)$ in the integrand is calculated as follows. First we sort the times τ_i according to their time order, denoting the reordered times by $\tau_{t(i)}$. We also set $\tau_b \equiv \tau_{t(n+1)}$ and $\tau_a \equiv \tau_{t(0)}$. Assuming that the times $\tau_{t(i)}$ are different from one another, we slice the time axis $\tau \in [\tau_a, \tau_b]$ into the intervals $[\tau_b, \tau_{t(n)}]$, $[\tau_{t(n)}, \tau_{t(n-1)}]$, $[\tau_{t(n-2)}, \tau_{t(n-3)}]$, \dots , $[\tau_{t(4)}, \tau_{t(3)}]$, $[\tau_{t(2)}, \tau_{t(1)}]$, $[\tau_{t(1)}, \tau_a]$. For each of these intervals we calculate the time evolution amplitude $(x_{t(i+1)}\tau_{t(i+1)} | x_{t(i)}\tau_{t(i)})$ as usual. Finally, we recombine the amplitudes by performing the intermediate $x(\tau_{t(i)})$ -integrations, with an extra factor $x(\tau_i)$ at each τ_i , i.e.,

$$\begin{aligned} G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) &= \prod_{i=1}^{n+1} \left[\int_{-\infty}^{\infty} dx_{\tau_{t(i)}} \right] (x_{t(n+1)}\tau_b | x_{t(n)}\tau_{t(n)}) \cdot x(\tau_{t(n)}) \cdot \dots \\ &\cdot (x_{t(i+1)}\tau_{t(i+1)} | x_{t(i)}\tau_{t(i)}) \cdot x(\tau_{t(i)}) \cdot (x_{t(i)}\tau_{t(i)} | x_{t(i-1)}\tau_{t(i-1)}) \cdot x(\tau_{t(i-1)}) \\ &\cdot \dots \cdot (x_{t(2)}\tau_{t(2)} | x_{t(1)}\tau_{t(1)}) \cdot x(\tau_{t(1)}) \cdot (x_{t(1)}\tau_{t(1)} | x_{t(0)}\tau_a). \end{aligned} \quad (3.301)$$

We have set $x_{t(n+1)} \equiv x_b = x_a \equiv x_{t(0)}$, in accordance with the periodic boundary condition. If two or more of the times τ_i are equal, the intermediate integrals are accompanied by the corresponding power of $x(\tau_i)$.

Fortunately, this rather complicated-looking expression can be replaced by a much simpler one involving functional derivatives of the thermal partition function $Z[j]$ in the presence of an external current j . From the definition of $Z[j]$ in (3.236) it is easy to see that all correlation functions of the system are obtained by the functional formula

$$G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) = \left[Z[j]^{-1} \hbar \frac{\delta}{\delta j(\tau_1)} \cdots \hbar \frac{\delta}{\delta j(\tau_n)} Z[j] \right]_{j=0}. \quad (3.302)$$

This is why $Z[j]$ is called the *generating functional* of the theory.

In the present case of a harmonic action, $Z[j]$ has the simple form (3.246), (3.247), and we can write

$$G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) = \left[\hbar \frac{\delta}{\delta j(\tau_1)} \cdots \hbar \frac{\delta}{\delta j(\tau_n)} \right] \quad (3.303)$$

$$\times \exp \left\{ \frac{1}{2\hbar M} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^p(\tau - \tau') j(\tau') \right\} \Big|_{j=0},$$

where $G_{\omega^2, e}^p(\tau - \tau')$ is the Euclidean Green function (3.251). Expanding the exponential into a Taylor series, the differentiations are easy to perform. Obviously, any odd number of derivatives vanishes. Differentiating (3.246) twice yields the two-point function [recall (3.251)]

$$G_{\omega^2}^{(2)}(\tau, \tau') = \langle x(\tau)x(\tau') \rangle = \frac{\hbar}{M} G_{\omega^2, e}^p(\tau - \tau'). \quad (3.304)$$

Thus, up to the constant prefactor, the two-point function coincides with the Euclidean Green function (3.251). Inserting (3.304) into (3.303), all n -point functions are expressed in terms of the two-point function $G_{\omega^2}^{(2)}(\tau, \tau')$: Expanding the exponential into a power series, the expansion term of order $n/2$ carries the numeric prefactors $1/(n/2)! \cdot 1/2^{n/2}$ and consists of a product of $n/2$ factors $\int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2}^{(2)}(\tau, \tau') j(\tau')/\hbar^2$. The n -point function is obtained by functionally differentiating this term n times. The result is a sum over products of $n/2$ factors $G_{\omega^2}^{(2)}(\tau, \tau')$ with $n!$ permutations of the n time arguments. Most of these products coincide, for symmetry reasons. First, $G_{\omega^2}^{(2)}(\tau, \tau')$ is symmetric in its arguments. Hence $2^{n/2}$ of the permutations correspond to identical terms, their number canceling one of the prefactors. Second, the $n/2$ Green functions $G_{\omega^2}^{(2)}(\tau, \tau')$ in the product are identical. Of the $n!$ permutations, subsets of $(n/2)!$ permutations produce identical terms, their number canceling the other prefactor. Only $n!/[(n/2)!2^{n/2}] = (n-1) \cdot (n-3) \cdots 1 = (n-1)!!$ terms are different. They all carry a unit prefactor and their sum is given by the so-called *Wick rule* or *Wick expansion*:

$$G_{\omega^2}^{(n)}(\tau_1, \dots, \tau_n) = \sum_{\text{pairs}} G_{\omega^2}^{(2)}(\tau_{p(1)}, \tau_{p(2)}) \cdots G_{\omega^2}^{(2)}(\tau_{p(n-1)}, \tau_{p(n)}). \quad (3.305)$$

Each term is characterized by a different pair configurations of the time arguments in the Green functions. These pair configurations are found most simply by the following rule: Write down all time arguments in the n -point function $\tau_1\tau_2\tau_3\tau_4 \dots \tau_n$. Indicate a pair by a common symbol, say $\dot{\tau}_{p(i)}\dot{\tau}_{p(i+1)}$, and call it a *pair contraction* to symbolize a Green function $G_{\omega^2}^{(2)}(\tau_{p(i)}, \tau_{p(i+1)})$. The desired $(n-1)!!$ pair configurations in the Wick expansion (3.305) are then found iteratively by forming $n-1$ single contractions

$$\dot{\tau}_1\dot{\tau}_2\tau_3\tau_4 \dots \tau_n + \dot{\tau}_1\tau_2\dot{\tau}_3\tau_4 \dots \tau_n + \dot{\tau}_1\tau_2\tau_3\dot{\tau}_4 \dots \tau_n + \dots + \dot{\tau}_1\tau_2\tau_3\tau_4 \dots \dot{\tau}_n, \quad (3.306)$$

and by treating the remaining $n-2$ uncontracted variables in each of these terms likewise, using a different contraction symbol. The procedure is continued until all variables are contracted.

In the literature, one sometimes another shorter formula under the name of Wick's rule, stating that a single harmonically fluctuating variable satisfies the equality of expectations:

$$\langle e^{Kx} \rangle = e^{K^2 \langle x^2 \rangle / 2}. \quad (3.307)$$

This follows from the observation that the generating functional (3.236) may also be viewed as Z_ω times the expectation value of the source exponential

$$Z_\omega[j] = Z_\omega \times \langle e^{\int d\tau j(\tau)x(\tau)/\hbar} \rangle. \quad (3.308)$$

Thus we can express the result (3.246) also as

$$\langle e^{\int d\tau j(\tau)x(\tau)/\hbar} \rangle = e^{(1/2M\hbar) \int d\tau \int d\tau' j(\tau)G_{\omega^2,e}^P(\tau,\tau')j(\tau')}. \quad (3.309)$$

Since $(\hbar/M)G_{\omega^2,e}^P(\tau,\tau')$ in the exponent is equal to the correlation function $G_{\omega^2}^{(2)}(\tau,\tau') = \langle x(\tau)x(\tau') \rangle$ by Eq. (3.304), we may also write

$$\langle e^{\int d\tau j(\tau)x(\tau)/\hbar} \rangle = e^{\int d\tau \int d\tau' j(\tau)\langle x(\tau)x(\tau') \rangle j(\tau')/2\hbar^2}. \quad (3.310)$$

Considering now a discrete time axis sliced at $t = t_n$, and inserting the special source current $j(\tau_n) = K\delta_{n,0}$, for instance, we find directly (3.307).

The Wick theorem in this form has an important physical application. The intensity of the sharp diffraction peaks observed in *Bragg scattering* of X-rays on crystal planes is reduced by thermal fluctuations of the atoms in the periodic lattice. The reduction factor is usually written as e^{-2W} and called the *Debye-Waller factor*. In the Gaussian approximation it is given by

$$e^{-W} \equiv \langle e^{-\nabla \cdot \mathbf{u}(\mathbf{x})} \rangle = e^{-\Sigma_{\mathbf{k}} \langle |\mathbf{k} \cdot \mathbf{u}(\mathbf{k})|^2 \rangle / 2}, \quad (3.311)$$

where $\mathbf{u}(\mathbf{x})$ is the atomic displacement field.

If the fluctuations take place around $\langle x(\tau) \rangle \neq 0$, then (3.307) goes obviously over into

$$\langle e^{Px} \rangle = e^{P\langle x(\tau) \rangle + P^2 \langle x - \langle x(\tau) \rangle \rangle^2 / 2}. \quad (3.312)$$

3.10.1 Real-Time Correlation Functions

The translation of these results to real times is simple. Consider, for example, the harmonic fluctuations $\delta x(t)$ with Dirichlet boundary conditions, which vanish at t_b and t_a . Their correlation functions can be found by using the amplitude (3.23) as a generating functional, if we replace $x(t) \rightarrow \delta x(t)$ and $x_b = x_a \rightarrow 0$. Differentiating twice with respect to the external currents $j(t)$ we obtain

$$G_{\omega^2}^{(2)}(t, t') = \langle x(t)x(t') \rangle = i \frac{\hbar}{M} G_{\omega^2}(t - t'), \quad (3.313)$$

with the Green function $G_{\omega^2}(t-t')$ of Eq. (3.36), which vanishes if $t = t_b$ or $t = t_a$. The correlation function of $\dot{x}(t)$ is

$$\langle \dot{x}(t)\dot{x}(t') \rangle = i \frac{\hbar}{M} \frac{\cos \omega(t_b - t_>) \cos \omega(t_< - t_a)}{\omega \sin \omega(t_b - t_a)}, \quad (3.314)$$

and has the value

$$\langle \dot{x}(t_b)\dot{x}(t_b) \rangle = i \frac{\hbar}{M} \cot \omega(t_b - t_a). \quad (3.315)$$

As an application, we use this result to calculate once more the time evolution amplitude $(\mathbf{x}_b t_b | \mathbf{x}_a t_a)$ in a way closely related to the operator method in Section 2.23. We observe that the time derivative of this amplitude has the path integral representation [compare (2.763)]

$$i\hbar \partial_{t_b} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = - \int \mathcal{D}^D x L(\mathbf{x}_b, \dot{\mathbf{x}}_b) e^{i \int_{t_a}^{t_b} dt L(\mathbf{x}, \dot{\mathbf{x}})/\hbar} = - \langle L(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle (\mathbf{x}_b t_b | \mathbf{x}_a t_a), \quad (3.316)$$

and calculate the expectation value $\langle L(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle$ as a sum of the classical Lagrangian $L(\mathbf{x}_{\text{cl}}(t_b), \dot{\mathbf{x}}_{\text{cl}}(t_b))$ and the expectation value of the fluctuating part of the Lagrangian $\langle L_{\text{fl}}(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle \equiv \langle [L(\mathbf{x}_b, \dot{\mathbf{x}}_b) - L(\mathbf{x}_{\text{cl}}(t_b), \dot{\mathbf{x}}_{\text{cl}}(t_b))] \rangle$. If the Lagrangian has the standard form $L = M\dot{\mathbf{x}}^2/2 - V(\mathbf{x})$, then only the kinetic term contributes to $\langle L_{\text{fl}}(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle$, so that

$$\langle L_{\text{fl}}(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle = \frac{M}{2} \langle \delta \dot{\mathbf{x}}_b^2 \rangle. \quad (3.317)$$

There is no contribution from $\langle V(\mathbf{x}_b) - V(\mathbf{x}_{\text{cl}}(t_b)) \rangle$, due to the Dirichlet boundary conditions.

The temporal integral over $-[L(\mathbf{x}_{\text{cl}}(t_b), \dot{\mathbf{x}}_{\text{cl}}(t_b)) - \langle L_{\text{fl}}(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle]$ agrees with the operator result (2.790), and we obtain the time evolution amplitude from the formula

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = C(\mathbf{x}_b, \mathbf{x}_a) e^{iA(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)/\hbar} \exp \left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt_b' \frac{M}{2} \langle \delta \dot{\mathbf{x}}_{b'}^2 \rangle \right), \quad (3.318)$$

where $A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)$ is the classical action $\mathcal{A}[\mathbf{x}_{\text{cl}}]$ expressed as a function of the endpoints [recall (4.87)]. The constant of integration $C(\mathbf{x}_b, \mathbf{x}_a)$ is fixed as in (2.776) by solving the differential equation

$$-i\hbar \nabla_b (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \langle \mathbf{p}_b \rangle (\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \mathbf{p}_{\text{cl}}(t_b) (\mathbf{x}_b t_b | \mathbf{x}_a t_a), \quad (3.319)$$

and a similar equation for \mathbf{x}_a [compare (2.777)]. Since the prefactor $\mathbf{p}_{\text{cl}}(t_b)$ on the right-hand side is obtained from the derivative of the exponential $e^{iA(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)/\hbar}$ in (3.318), due to the general relation (4.88), the constant of integration $C(\mathbf{x}_b, \mathbf{x}_a)$ is actually independent of \mathbf{x}_b and \mathbf{x}_a . Thus we obtain from (3.318) once more the known result (3.318).

As an example, take the harmonic oscillator. The terms linear in $\delta \mathbf{x}(t) = \mathbf{x}(t) - \mathbf{x}_{\text{cl}}(t)$ vanish since they are odd in $\delta \mathbf{x}(t)$ while the exponent in (3.316) is

even. Inserting on the right-hand side of (3.317) the correlation function (3.314), we obtain in D dimensions

$$\langle L_{\text{fl}}(\mathbf{x}_b, \dot{\mathbf{x}}_b) \rangle = \frac{M}{2} \langle \delta \dot{\mathbf{x}}_b^2 \rangle = i \frac{\hbar \omega}{2} D \cot \omega(t_b - t_a), \quad (3.320)$$

which is precisely the second term in Eq. (2.789), with the appropriate opposite sign.

3.11 Correlation Functions of Charged Particle in Magnetic Field and Harmonic Potential

It is straightforward to find the correlation functions of a charged particle in a magnetic and an extra harmonic potential discussed in Section 2.19. They are obtained by inverting the functional matrix (2.693):

$$\mathbf{G}_{\omega^2, B}^{(2)}(\tau, \tau') = \frac{\hbar}{M} \mathbf{D}_{\omega^2, B}^{-1}(\tau, \tau'). \quad (3.321)$$

By an ordinary matrix inversion of (2.696), we obtain the Fourier expansion

$$\mathbf{G}_B^{(2)}(\tau, \tau') = \frac{1}{\hbar \beta} \sum_{m=-\infty}^{\infty} \tilde{\mathbf{G}}_{\omega^2, B}(\omega_m) e^{-i\omega_m(\tau - \tau')}, \quad (3.322)$$

with

$$\tilde{\mathbf{G}}_{\omega^2, B}^{(2)}(\omega_m) = \frac{\hbar}{M} \frac{1}{(\omega_m^2 + \omega_+^2)(\omega_m^2 + \omega_-^2)} \begin{pmatrix} \omega_m^2 + \omega^2 - \omega_B^2 & 2\omega_B \omega_m \\ -2\omega_B \omega_m & \omega_m^2 + \omega^2 - \omega_B^2 \end{pmatrix}. \quad (3.323)$$

Since $\omega_+^2 + \omega_-^2 = 2(\omega^2 + \omega_B^2)$ and $\omega_+^2 - \omega_-^2 = 4\omega\omega_B$, the diagonal elements can be written as

$$\begin{aligned} & \frac{1}{2(\omega_m^2 + \omega_+^2)(\omega_m^2 + \omega_-^2)} [(\omega_m^2 + \omega_+^2) + (\omega_m^2 + \omega_-^2) - 4\omega_B^2] \\ &= \frac{1}{2} \left\{ \left[\frac{1}{\omega_m^2 + \omega_+^2} + \frac{1}{\omega_m^2 + \omega_-^2} \right] + \frac{\omega_B}{\omega} \left[\frac{1}{\omega_m^2 + \omega_+^2} - \frac{1}{\omega_m^2 + \omega_-^2} \right] \right\}. \end{aligned} \quad (3.324)$$

Recalling the Fourier expansion (3.248), we obtain directly the diagonal periodic correlation function

$$G_{\omega^2, B, xx}^{(2)} = \frac{\hbar}{4M\omega} \left[\frac{\cosh \omega_+(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_+ \hbar\beta/2)} + \frac{\cosh \omega_-(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_- \hbar\beta/2)} \right], \quad (3.325)$$

which is equal to $G_{\omega^2, B, yy}^{(2)}$. The off-diagonal correlation functions have the Fourier components

$$\frac{2\omega_B \omega_m}{(\omega_m^2 + \omega_+^2)(\omega_m^2 + \omega_-^2)} = \frac{\omega_m}{2\omega} \left[\frac{1}{\omega_m^2 + \omega_+^2} - \frac{1}{\omega_m^2 + \omega_-^2} \right]. \quad (3.326)$$

Since ω_m are the Fourier components of the derivative $i\partial_\tau$, we can write

$$G_{\omega^2, B, xy}^{(2)}(\tau, \tau') = -G_{\omega^2, B, yx}^{(2)}(\tau, \tau') = \frac{\hbar}{2M} i\partial_\tau \left[\frac{1}{2\omega_+} \frac{\cosh \omega_+(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_+\hbar\beta/2)} - \frac{1}{2\omega_-} \frac{\cosh \omega_-(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_-\hbar\beta/2)} \right]. \quad (3.327)$$

Performing the derivatives yields

$$G_{\omega^2, B, xy}^{(2)}(\tau, \tau') = G_{\omega^2, B, yx}^{(2)}(\tau, \tau') = \frac{\hbar\epsilon(\tau - \tau')}{2Mi} \left[\frac{1}{2\omega_+} \frac{\sinh \omega_+(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_+\hbar\beta/2)} - \frac{1}{2\omega_-} \frac{\sinh \omega_-(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega_-\hbar\beta/2)} \right], \quad (3.328)$$

where $\epsilon(\tau - \tau')$ is the step function (1.315).

For a charged particle in a magnetic field without an extra harmonic oscillator we have to take the limit $\omega \rightarrow \omega_B$ in these equations. Due to translational invariance of the limiting system, this exists only after removing the zero-mode in the Matsubara sum. This is done most simply in the final expressions by subtracting the high-temperature limits at $\tau = \tau'$. In the diagonal correlation functions (3.325) this yields

$$G_{\omega^2, B, xx}^{(2)'}(\tau, \tau') = G_{\omega^2, B, yy}^{(2)'}(\tau, \tau') = G_{\omega^2, B, xx}^{(2)} - \frac{1}{\beta M \omega_+ \omega_-}, \quad (3.329)$$

where the prime indicates the subtraction. Now one can easily go to the limit $\omega \rightarrow \omega_B$ with the result

$$G_{\omega^2, B, xx}^{(2)'}(\tau, \tau') = G_{\omega^2, B, yy}^{(2)'}(\tau, \tau') = \frac{\hbar}{4M\omega} \left[\frac{\cosh 2\omega(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\beta\hbar\omega)} - \frac{1}{\omega\hbar\beta} \right]. \quad (3.330)$$

For the subtracted off-diagonal correlation functions (3.328) we find

$$G_{\omega^2, B, xy}^{(2)'}(\tau, \tau') = -G_{\omega^2, B, yx}^{(2)'}(\tau, \tau') = G_{\omega^2, B, xy}^{(2)} + \frac{\hbar\omega_B}{2Mi\omega_+\omega_-} \epsilon(\tau - \tau'). \quad (3.331)$$

For more details see the literature.⁷

3.12 Correlation Functions in Canonical Path Integral

Sometimes it is desirable to know the correlation functions of position and momentum variables

$$\begin{aligned} G_{\omega^2}^{(m,n)}(\tau_1, \dots, \tau_m; \tau_1, \dots, \tau_n) &\equiv \langle x(\tau_1)x(\tau_2)\cdots x(\tau_m)p(\tau_1)p(\tau_2)\cdots p(\tau_n) \rangle \\ &\equiv Z^{-1} \int \mathcal{D}x(\tau) \int \frac{\mathcal{D}p(\tau)}{2\pi} x(\tau_1)x(\tau_2)\cdots x(\tau_m)p(\tau_1)p(\tau_2)\cdots p(\tau_n) \exp\left(-\frac{1}{\hbar}\mathcal{A}_e\right). \end{aligned} \quad (3.332)$$

These can be obtained from a direct extension of the generating functional (3.236) by another source $k(\tau)$ coupled linearly to the momentum variable $p(\tau)$:

$$Z[j, k] = \int \mathcal{D}x(\tau) e^{-\mathcal{A}_e[j, k]/\hbar}. \quad (3.333)$$

⁷M. Bachmann, H. Kleinert, and A. Pelster, Phys. Rev. A 62, 52509 (2000) (quant-ph/0005074); Phys. Lett. A 279, 23 (2001) (quant-ph/0005100).

3.12.1 Harmonic Correlation Functions

For the harmonic oscillator, the generating functional (3.333) is denoted by $Z_\omega[j, k]$ and its Euclidean action reads

$$\mathcal{A}_e[j, k] = \int_0^{\hbar\beta} d\tau \left[-ip(\tau)\dot{x}(\tau) + \frac{1}{2M}p^2 + \frac{M}{2}\omega^2 x^2 - j(\tau)x(\tau) - k(\tau)p(\tau) \right], \quad (3.334)$$

the partition function is denoted by $Z_\omega[j, k]$. Introducing the vectors in phase space $\mathbf{V}(\tau) = (p(\tau), x(\tau))$ and $\mathbf{J}(\tau) = (j(\tau), k(\tau))$, this can be written in matrix form as

$$\mathcal{A}_e[\mathbf{J}] = \int_0^{\hbar\beta} d\tau \left(\frac{1}{2} \mathbf{V}^T \mathbf{D}_{\omega^2, e} \mathbf{V} - \mathbf{V}^T \mathbf{J} \right), \quad (3.335)$$

where $\mathbf{D}_{\omega^2, e}(\tau, \tau')$ is the functional matrix

$$\mathbf{D}_{\omega^2, e}(\tau, \tau') \equiv \begin{pmatrix} M\omega^2 & i\partial_\tau \\ -i\partial_\tau & M^{-1} \end{pmatrix} \delta(\tau - \tau'), \quad \tau - \tau' \in [0, \hbar\beta]. \quad (3.336)$$

Its functional inverse is the Euclidean Green function,

$$\begin{aligned} \mathbf{G}_{\omega^2, e}^p(\tau, \tau') &= \mathbf{G}_{\omega^2, e}^p(\tau - \tau') = \mathbf{D}_{\omega^2, e}^{-1}(\tau, \tau') \\ &= \begin{pmatrix} M^{-1} & -i\partial_\tau \\ i\partial_\tau & M\omega^2 \end{pmatrix} (-\partial_\tau^2 + \omega^2)^{-1} \delta(\tau - \tau'), \end{aligned} \quad (3.337)$$

with the periodic boundary condition. After performing a quadratic completion as in (3.241) by shifting the path:

$$\mathbf{V} \rightarrow \mathbf{V}' = \mathbf{V} + \mathbf{G}_{\omega^2, e}^p \mathbf{J}, \quad (3.338)$$

the Euclidean action takes the form

$$\mathcal{A}_e[\mathbf{J}] = \int_0^{\hbar\beta} d\tau \frac{1}{2} \mathbf{V}'^T \mathbf{D}_{\omega^2, e} \mathbf{V}' - \frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \mathbf{J}^T(\tau') \mathbf{G}_{\omega^2, e}^p(\tau - \tau') \mathbf{J}(\tau'). \quad (3.339)$$

The fluctuations over the periodic paths $\mathbf{V}'(\tau)$ can now be integrated out and yield for $\mathbf{J}(\tau) \equiv 0$ the oscillator partition function

$$Z_\omega = \text{Det } \mathbf{D}_{\omega^2, e}^{-1/2}. \quad (3.340)$$

A Fourier decomposition into Matsubara frequencies

$$\mathbf{D}_{\omega^2, e}(\tau, \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \mathbf{D}_{\omega^2, e}^p(\omega_m) e^{-i\omega_m(\tau - \tau')}, \quad (3.341)$$

has the components

$$\mathbf{D}_{\omega^2, e}^p(\omega_m) = \begin{pmatrix} M^{-1} & \omega_m \\ -\omega_m & M\omega^2 \end{pmatrix}, \quad (3.342)$$

with the determinants

$$\det \mathbf{D}_{\omega^2, e}^p(\omega_m) = \omega_m^2 + \omega^2, \quad (3.343)$$

and the inverses

$$\mathbf{G}_e^p(\omega_m) = [\mathbf{D}_{\omega^2, e}^p(\omega_m)]^{-1} = \begin{pmatrix} M\omega^2 & -\omega_m \\ \omega_m & M^{-1} \end{pmatrix} \frac{1}{\omega_m^2 + \omega^2}. \quad (3.344)$$

The product of determinants (3.343) for all ω_m required in the functional determinant of Eq. (3.340) is calculated with the rules of analytic regularization in Section 2.15, and yields the same partition function as in (3.244), and thus the same partition function (3.245):

$$Z_\omega = \frac{1}{\prod_{m=1}^{\infty} \sqrt{\omega_m^2 + \omega^2}} = \frac{1}{2 \sinh(\beta \hbar \omega / 2)}. \quad (3.345)$$

We therefore obtain for arbitrary sources $\mathbf{J}(\tau) = (j(\tau), k(\tau)) \neq 0$ the generating functional

$$Z[\mathbf{J}] = Z_\omega \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_e^{\mathbf{J}}[\mathbf{J}] \right\}, \quad (3.346)$$

with the source term

$$\mathcal{A}_e^{\mathbf{J}}[\mathbf{J}] = -\frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \mathbf{J}^T(\tau) \mathbf{G}_{\omega^2, e}^{\text{P}}(\tau, \tau') \mathbf{J}(\tau'). \quad (3.347)$$

The Green function $\mathbf{G}_{\omega^2, e}^{\text{P}}(\tau, \tau')$ follows immediately from Eq. (3.337) and (3.240):

$$\mathbf{G}_{\omega^2, e}^{\text{P}}(\tau, \tau') = \mathbf{G}_{\omega^2, e}^{\text{P}}(\tau - \tau') = \mathbf{D}_{\omega^2, e}^{-1}(\tau, \tau') = \begin{pmatrix} M^{-1} & -i\partial_\tau \\ i\partial_\tau & M\omega^2 \end{pmatrix} G_{\omega^2, e}^{\text{P}}(\tau - \tau'), \quad (3.348)$$

where $G_{\omega^2, e}^{\text{P}}(\tau - \tau')$ is the simple periodic Green function (3.251). From the functional derivatives of (3.346) with respect to $j(\tau)/\hbar$ and $k(\tau)/\hbar$ as in (3.302), we now find the correlation functions

$$G_{\omega^2, e, xx}^{(2)}(\tau, \tau') \equiv \langle x(\tau)x(\tau') \rangle = \frac{\hbar}{M} G_{\omega^2, e}^{\text{P}}(\tau - \tau'), \quad (3.349)$$

$$G_{\omega^2, e, xp}^{(2)}(\tau, \tau') \equiv \langle x(\tau)p(\tau') \rangle = -i\hbar \dot{G}_{\omega^2, e}^{\text{P}}(\tau - \tau'), \quad (3.350)$$

$$G_{\omega^2, e, px}^{(2)}(\tau, \tau') \equiv \langle p(\tau)x(\tau') \rangle = i\hbar \dot{G}_{\omega^2, e}^{\text{P}}(\tau - \tau'), \quad (3.351)$$

$$G_{\omega^2, e, pp}^{(2)}(\tau, \tau') \equiv \langle p(\tau)p(\tau') \rangle = \hbar M \omega^2 G_{\omega^2, e}^{\text{P}}(\tau - \tau'). \quad (3.352)$$

The correlation function $\langle x(\tau)x(\tau') \rangle$ is the same as in the pure configuration space formulation (3.304). The mixed correlation function $\langle p(\tau)x(\tau') \rangle$ is understood immediately by rewriting the current-free part of the action (3.334) as

$$\mathcal{A}_e[0, 0] = \int_0^{\hbar\beta} d\tau \left[\frac{1}{2M} (p - iM\dot{x})^2 + \frac{M}{2} (\dot{x}^2 + \omega^2 x^2) \right], \quad (3.353)$$

which shows that $p(\tau)$ fluctuates harmonically around the classical momentum for imaginary time $iM\dot{x}(\tau)$. It is therefore not surprising that the correlation function $\langle p(\tau)x(\tau') \rangle$ comes out to be the same as that of $iM\langle \dot{x}(\tau)x(\tau') \rangle$. Such an analogy is no longer true for the correlation function $\langle p(\tau)p(\tau') \rangle$. In fact, the correlation function $\langle \dot{x}(\tau)\dot{x}(\tau') \rangle$ is equal to

$$\langle \dot{x}(\tau)\dot{x}(\tau') \rangle = -\hbar M \partial_\tau^2 G_{\omega^2, e}^{\text{P}}(\tau - \tau'). \quad (3.354)$$

Comparison with (3.352) reveals the relation

$$\begin{aligned} \langle p(\tau)p(\tau') \rangle &= \langle \dot{x}(\tau)\dot{x}(\tau') \rangle + \frac{\hbar}{M} (-\partial_\tau^2 + \omega^2) G_{\omega^2, e}^{\text{P}}(\tau - \tau') \\ &= \langle \dot{x}(\tau)\dot{x}(\tau') \rangle + \frac{\hbar}{M} \delta(\tau - \tau'). \end{aligned} \quad (3.355)$$

The additional δ -function on the right-hand side is the consequence of the fact that $p(\tau)$ is not equal to $iM\dot{x}$, but fluctuates around it harmonically.

For the canonical path integral of a particle in a uniform magnetic field solved in Section 2.18, there are analogous relations. Here we write the canonical action (2.643) with a vector potential (2.640) in the Euclidean form as

$$\mathcal{A}_e[\mathbf{p}, \mathbf{x}] = \int_0^{\hbar\beta} d\tau \left\{ \frac{1}{2M} \left[\mathbf{p} - \frac{e}{c} \mathbf{B} \times \mathbf{x} - iM\dot{\mathbf{x}} \right]^2 + \frac{M}{2} \omega^2 \mathbf{x}^2 \right\}, \quad (3.356)$$

showing that $\mathbf{p}(\tau)$ fluctuates harmonically around the classical momentum $\mathbf{p}_{cl}(\tau) = (e/c)\mathbf{B} \times \mathbf{x} - iM\dot{\mathbf{x}}$. For a magnetic field pointing in the z -direction we obtain, with the frequency $\omega_B = \omega_L/2$ of Eq. (2.648), the following relations between the correlation functions involving momenta and those involving only coordinates given in (3.325), (3.327), (3.327):

$$G_{\omega^2, B, xp_x}^{(2)}(\tau, \tau') \equiv \langle x(\tau)p_x(\tau') \rangle = iM\partial_{\tau'} G_{\omega^2, B, xx}^{(2)}(\tau, \tau') - M\omega_B G_{\omega^2, B, xy}^{(2)}(\tau, \tau'), \quad (3.357)$$

$$G_{\omega^2, B, xp_y}^{(2)}(\tau, \tau') \equiv \langle x(\tau)p_y(\tau') \rangle = iM\partial_{\tau'} G_{\omega^2, B, xy}^{(2)}(\tau, \tau') + M\omega_B G_{\omega^2, B, xx}^{(2)}(\tau, \tau'), \quad (3.358)$$

$$G_{\omega^2, B, zp_z}^{(2)}(\tau, \tau') \equiv \langle z(\tau)p_z(\tau') \rangle = iM\partial_{\tau'} G_{\omega^2, B, zz}^{(2)}(\tau, \tau'), \quad (3.359)$$

$$G_{\omega^2, B, p_x p_x}^{(2)}(\tau, \tau') \equiv \langle p_x(\tau)p_x(\tau') \rangle = -M^2\partial_{\tau}\partial_{\tau'} G_{\omega^2, B, xx}^{(2)}(\tau, \tau') - 2iM^2\omega_B\partial_{\tau} G_{\omega^2, B, xy}^{(2)}(\tau, \tau') \\ + M^2\omega_B^2 G_{\omega^2, B, xx}^{(2)}(\tau, \tau') + \hbar M\delta(\tau - \tau'), \quad (3.360)$$

$$G_{\omega^2, B, p_x p_y}^{(2)}(\tau, \tau') \equiv \langle p_x(\tau)p_y(\tau') \rangle = -M^2\partial_{\tau}\partial_{\tau'} G_{\omega^2, B, xy}^{(2)}(\tau, \tau') + iM^2\partial_{\tau} G_{\omega^2, B, xx}^{(2)}(\tau, \tau') \\ + M^2\omega_B^2 G_{\omega^2, B, xy}^{(2)}(\tau, \tau'), \quad (3.361)$$

$$G_{\omega^2, B, p_z p_z}^{(2)}(\tau, \tau') \equiv \langle p_z(\tau)p_z(\tau') \rangle = -M^2\partial_{\tau}\partial_{\tau'} G_{\omega^2, B, zz}^{(2)}(\tau, \tau') + \hbar M\delta(\tau - \tau'). \quad (3.362)$$

Only diagonal correlations between momenta contain the extra δ -function on the right-hand side according to the rule (3.355). Note that $\partial_{\tau}\partial_{\tau'} G_{\omega^2, B, ab}^{(2)}(\tau, \tau') = -\partial_{\tau}^2 G_{\omega^2, B, ab}^{(2)}(\tau, \tau')$. Each correlation function is, of course, invariant under time translations, depending only on the time difference $\tau - \tau'$.

The correlation functions $\langle x(\tau)x(\tau') \rangle$ and $\langle x(\tau)y(\tau') \rangle$ are the same as before in Eqs. (3.327) and (3.328).

3.12.2 Relations between Various Amplitudes

A slight generalization of the generating functional (3.333) contains paths with fixed endpoints rather than all periodic paths. If the endpoints are held fixed in configuration space, one defines

$$(x_b \hbar\beta | x_a 0)[j, k] = \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} Dx \frac{Dp}{2\pi\hbar} \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_e[j, k] \right\}. \quad (3.363)$$

If the endpoints are held fixed in momentum space, one defines

$$(p_b \hbar\beta | p_a 0)[j, k] = \int_{p(0)=p_a}^{p(\hbar\beta)=p_b} Dx \frac{Dp}{2\pi\hbar} \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_e[j, k] \right\}. \quad (3.364)$$

The two are related by a Fourier transformation

$$(p_b \hbar\beta | p_a 0)[j, k] = \int_{-\infty}^{+\infty} dx_a \int_{-\infty}^{+\infty} dx_b e^{-i(p_b x_b - p_a x_a)/\hbar} (x_b \hbar\beta | x_a 0)[j, k]. \quad (3.365)$$

We now observe that in the canonical path integral, the amplitudes (3.363) and (3.364) with fixed endpoints can be reduced to those with vanishing endpoints with modified sources. The modification consists in shifting the current $k(\tau)$ in the action by the source term $ix_b\delta(\tau_b - \tau) -$

$ix_a\delta(\tau - \tau_a)$ and observe that this produces in (3.364) an overall phase factor in the limit $\tau_b \uparrow \hbar\beta$ and $\tau_a \downarrow 0$:

$$\begin{aligned} & \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} (p_b \hbar\beta | p_a 0) [j(\tau), k(\tau) + ix_b\delta(\tau_b - \tau) - ix_a\delta(\tau - \tau_a)] \\ &= \exp \left\{ \frac{i}{\hbar} (p_b x_b - p_a x_a) \right\} (p_b \hbar\beta | p_a 0) [j(\tau), k(\tau)]. \end{aligned} \quad (3.366)$$

By inserting (3.366) into the inverse of the Fourier transformation (3.365),

$$(x_b \hbar\beta | x_a 0) [j, k] = \int_{-\infty}^{+\infty} \frac{dp_a}{2\pi\hbar} \int_{-\infty}^{+\infty} \frac{dp_b}{2\pi\hbar} e^{i(p_b x_b - p_a x_a)/\hbar} (p_b \hbar\beta | p_a 0) [j, k], \quad (3.367)$$

we obtain

$$(x_b \hbar\beta | x_a 0) [j, k] = \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} (0 \hbar\beta | 0 0) [j(\tau), k(\tau) + ix_b\delta(\tau_b - \tau) - ix_a\delta(\tau - \tau_a)]. \quad (3.368)$$

In this way, the fixed-endpoint path integral (3.363) can be reduced to a path integral with vanishing endpoints but additional δ -terms in the current $k(\tau)$ coupled to the momentum $p(\tau)$.

There is also a simple relation between path integrals with fixed equal endpoints and periodic path integrals. The measures of integration are related by

$$\int_{x(0)=x}^{x(\hbar\beta)=x} \frac{\mathcal{D}x\mathcal{D}p}{2\pi\hbar} = \oint \frac{\mathcal{D}x\mathcal{D}p}{2\pi\hbar} \delta(x(0) - x). \quad (3.369)$$

Using the Fourier decomposition of the delta function, we rewrite (3.369) as

$$\int_{x(0)=x}^{x(\hbar\beta)=x} \frac{\mathcal{D}x\mathcal{D}p}{2\pi\hbar} = \lim_{\tau'_a \downarrow 0} \int_{-\infty}^{+\infty} \frac{dp_a}{2\pi\hbar} e^{ip_a x/\hbar} \oint \frac{\mathcal{D}x\mathcal{D}p}{2\pi\hbar} e^{-i \int_0^{\hbar\beta} d\tau p_a \delta(\tau - \tau'_a) x(\tau)/\hbar}. \quad (3.370)$$

Inserting now (3.370) into (3.368) leads to the announced desired relation

$$\begin{aligned} (x_b \hbar\beta | x_a 0) [k, j] &= \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} \lim_{\tau'_a \downarrow 0} \int_{-\infty}^{+\infty} \frac{dp_a}{2\pi\hbar} \\ &\times Z [j(\tau) - ip_a \delta(\tau - \tau'_a), k(\tau) + ix_b \delta(\tau_b - \tau) - ix_a \delta(\tau - \tau_a)], \end{aligned} \quad (3.371)$$

where $Z[j, k]$ is the thermodynamic partition function (3.333) summing all periodic paths. When using (3.371) we must be careful in evaluating the three limits. The limit $\tau'_a \downarrow 0$ has to be evaluated prior to the other limits $\tau_b \uparrow \hbar\beta$ and $\tau_a \downarrow 0$.

3.12.3 Harmonic Generating Functionals

Here we write down explicitly the harmonic generating functionals with the above shifted source terms:

$$\tilde{k}(\tau) = k(\tau) + ix_b \delta(\tau_b - \tau) - ix_a \delta(\tau - \tau_a), \quad \tilde{j}(\tau) = j(\tau) - ip \delta(\tau - \tau'_a), \quad (3.372)$$

leading to the factorized generating functional

$$Z_\omega[\tilde{k}, \tilde{j}] = Z_\omega^{(0)}[0, 0] Z_\omega^{(1)}[k, j] Z_\omega^p[k, j]. \quad (3.373)$$

The respective terms on the right-hand side of (3.373) read in detail

$$Z_\omega^{(0)}[0, 0] = Z_\omega \exp \left(\frac{1}{2\hbar^2} \left\{ -p^2 G_{xx}^p(\tau'_a, \tau'_a) - 2p [x_a G_{xp}^p(\tau'_a, \tau_a) + x_b G_{xp}^p(\tau'_a, \tau_b)] \right\} \right)$$

$$-x_a^2 G_{pp}^p(\tau_a, \tau_a) - x_b^2 G_{pp}^p(\tau_b, \tau_b) + 2x_a x_b G_{pp}^p(\tau_a, \tau_b)\}, \quad (3.374)$$

$$Z_\omega^{(1)}[k, j] = \exp\left(\frac{1}{\hbar^2} \int_0^{\hbar\beta} d\tau \{j(\tau)[-ipG_{xx}^p(\tau, \tau'_a) + ix_b G_{xp}^p(\tau, \tau_b) - ix_a G_{xp}^p(\tau, \tau_a)]\right. \\ \left.+ k(\tau)[-ipG_{xp}^p(\tau, \tau'_a) + ix_b G_{pp}^p(\tau, \tau_b) - ix_a G_{pp}^p(\tau, \tau_a)]\}\right), \quad (3.375)$$

$$Z_\omega^p[k, j] = \exp\left\{\frac{1}{2\hbar^2} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 [(j(\tau_1), k(\tau_2))\right. \\ \left.\times \begin{pmatrix} G_{xx}^p(\tau_1, \tau_1) & G_{xp}^p(\tau_1, \tau_2) \\ G_{px}^p(\tau_1, \tau_2) & G_{pp}^p(\tau_1, \tau_2) \end{pmatrix} \begin{pmatrix} j(\tau_2) \\ k(\tau_2) \end{pmatrix})\right\}, \quad (3.376)$$

where Z_ω is given by (3.345) and $G_{xp}^p(\tau_1, \tau_2)$ etc. are the periodic Euclidean Green functions $G_{\omega^2, e, ab}^{(2)}(\tau_1, \tau_2)$ defined in Eqs. (3.349)–(3.352) in an abbreviated notation. Inserting (3.373) into (3.371) and performing the Gaussian momentum integration, over the exponentials in $Z_\omega^{(0)}[0, 0]$ and $Z_\omega^{(1)}[k, j]$, the result is

$$(x_b \hbar\beta | x_a 0)[k, j] = (x_b \hbar\beta | x_a 0)[0, 0] \times \exp\left\{\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau [x_{cl}(\tau)j(\tau) + p_{cl}(\tau)k(\tau)]\right\} \\ \times \exp\left\{\frac{1}{2\hbar^2} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 [(j(\tau_1), k(\tau_2)) \begin{pmatrix} G_{xx}^{(D)}(\tau_1, \tau_2) & G_{xp}^{(D)}(\tau_1, \tau_2) \\ G_{px}^{(D)}(\tau_1, \tau_2) & G_{pp}^{(D)}(\tau_1, \tau_2) \end{pmatrix} \begin{pmatrix} j(\tau_2) \\ k(\tau_2) \end{pmatrix})\right\}, \quad (3.377)$$

where the Green functions $G_{ab}^{(D)}(\tau_1, \tau_2)$ have now Dirichlet boundary conditions. In particular, the Green function $G_{ab}^{(D)}(\tau_1, \tau_2)$ is equal to (3.36) continued to imaginary time. The Green functions $G_{xp}^{(D)}(\tau_1, \tau_2)$ and $G_{pp}^{(D)}(\tau_1, \tau_2)$ are Dirichlet versions of Eqs. (3.349)–(3.352) which arise from the above Gaussian momentum integrals.

After performing the integrals, the first factor without currents is

$$(x_b \hbar\beta | x_a 0)[0, 0] = \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} \lim_{\tau'_a \downarrow 0} \frac{Z_\omega}{2\pi\hbar} \sqrt{\frac{2\pi\hbar^2}{G_{xx}^p(\tau'_a, \tau'_a)}} \\ \times \exp\left[\frac{1}{2\hbar^2} \left(x_a^2 \left\{\frac{G_{xp}^p(\tau'_a, \tau_a)}{G_{xx}^p(\tau'_a, \tau'_a)} - G_{pp}^p(\tau_a, \tau_a)\right\} + x_b^2 \left\{\frac{G_{xp}^p(\tau'_a, \tau_b)}{G_{xx}^p(\tau'_a, \tau'_a)} - G_{pp}^p(\tau_b, \tau_b)\right\}\right. \right. \\ \left. \left. - 2x_a x_b \left\{\frac{G_{xp}^p(\tau'_a, \tau_a)G_{xp}^p(\tau'_a, \tau_b)}{G_{xx}^p(\tau'_a, \tau'_a)} - G_{pp}^p(\tau_a, \tau_b)\right\}\right)\right]. \quad (3.378)$$

Performing the limits using

$$\lim_{\tau_a \downarrow 0} \lim_{\tau'_a \downarrow 0} G_{xp}^p(\tau'_a, \tau_a) = -i\frac{\hbar}{2}, \quad (3.379)$$

where the order of the respective limits turns out to be important, we obtain the amplitude (2.411):

$$(x_b \hbar\beta | x_a 0)[0, 0] = \sqrt{\frac{M\omega}{2\pi\hbar \sinh \hbar\beta\omega}} \\ \times \exp\left\{-\frac{M\omega}{2\hbar \sinh \hbar\beta\omega} [(x_a^2 + x_b^2) \cosh \hbar\beta\omega - 2x_a x_b]\right\}. \quad (3.380)$$

The first exponential in (3.377) contains a complicated representation of the classical path

$$x_{cl}(\tau) = \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} \lim_{\tau'_a \downarrow 0} \frac{i}{\hbar} \left\{x_a \left[\frac{G_{xp}^p(\tau'_a, \tau_a)G_{xx}^p(\tau, \tau'_a)}{G_{xx}^p(\tau'_a, \tau'_a)} + G_{xp}^p(\tau_a, \tau)\right]\right\}$$

$$-x_b \left[\frac{G_{xp}^p(\tau'_a, \tau_b) G_{xx}^p(\tau, \tau'_a)}{G_{xx}^p(\tau'_a, \tau'_a)} + G_{xp}^p(\tau_b, \tau) \right] \Big\} , \quad (3.381)$$

and of the classical momentum

$$p_{cl}(\tau) = \lim_{\tau_b \uparrow \hbar\beta} \lim_{\tau_a \downarrow 0} \lim_{\tau'_a \downarrow 0} \frac{i}{\hbar} \left\{ x_a \left[\frac{G_{xp}^p(\tau'_a, \tau_a) G_{xp}^p(\tau'_a, \tau)}{G_{xx}^p(\tau'_a, \tau'_a)} - G_{pp}^p(\tau_a, \tau) \right] - x_b \left[\frac{G_{xp}^p(\tau'_a, \tau_b) G_{xp}^p(\tau'_a, \tau)}{G_{xx}^p(\tau'_a, \tau'_a)} - G_{pp}^p(\tau_b, \tau) \right] \right\} . \quad (3.382)$$

Indeed, inserting the explicit periodic Green functions (3.349)–(3.352) and going to the limits we obtain

$$x_{cl}(\tau) = \frac{x_a \sinh \omega(\hbar\beta - \tau) + x_b \sinh \omega\tau}{\sinh \hbar\beta\omega} \quad (3.383)$$

and

$$p_{cl}(\tau) = iM\omega \frac{-x_a \cosh \omega(\hbar\beta - \tau) + x_b \cosh \omega\tau}{\sinh \hbar\beta\omega} , \quad (3.384)$$

the first being the imaginary-time version of the classical path (3.6), the second being related to it by the classical relation $p_{cl}(\tau) = iM dx_{cl}(\tau)/d\tau$.

The second exponential in (3.377) quadratic in the currents contains the Green functions with Dirichlet boundary conditions

$$G_{xx}^{(D)}(\tau_1, \tau_2) = G_{xx}^p(\tau_1, \tau_2) - \frac{G_{xx}^p(\tau_1, 0) G_{xx}^p(\tau_2, 0)}{G_{xx}^p(\tau_1, \tau_1)} , \quad (3.385)$$

$$G_{xp}^{(D)}(\tau_1, \tau_2) = G_{xp}^p(\tau_1, \tau_2) + \frac{G_{xx}^p(\tau_1, 0) G_{xp}^p(\tau_2, 0)}{G_{xx}^p(\tau_1, \tau_1)} , \quad (3.386)$$

$$G_{px}^{(D)}(\tau_1, \tau_2) = G_{px}^p(\tau_1, \tau_2) + \frac{G_{xp}^p(\tau_1, 0) G_{xx}^p(\tau_2, 0)}{G_{xx}^p(\tau_1, \tau_1)} , \quad (3.387)$$

$$G_{pp}^{(D)}(\tau_1, \tau_2) = G_{pp}^p(\tau_1, \tau_2) - \frac{G_{xp}^p(\tau_1, 0) G_{xp}^p(\tau_2, 0)}{G_{xx}^p(\tau_1, \tau_1)} . \quad (3.388)$$

After applying some trigonometric identities, these take the form

$$G_{xx}^{(D)}(\tau_1, \tau_2) = \frac{\hbar}{2M\omega \sinh \hbar\beta\omega} [\cosh \omega(\hbar\beta - |\tau_1 - \tau_2|) - \cosh \omega(\hbar\beta - \tau_1 - \tau_2)] , \quad (3.389)$$

$$G_{xp}^{(D)}(\tau_1, \tau_2) = \frac{i\hbar}{2 \sinh \hbar\beta\omega} \{ \theta(\tau_1 - \tau_2) \sinh \omega(\hbar\beta - |\tau_1 - \tau_2|) - \theta(\tau_2 - \tau_1) \sinh \omega(\hbar\beta - |\tau_2 - \tau_1|) + \sinh \omega(\hbar\beta - \tau_1 - \tau_2) \} , \quad (3.390)$$

$$G_{px}^{(D)}(\tau_1, \tau_2) = -\frac{i\hbar}{2 \sinh \hbar\beta\omega} \{ \theta(\tau_1 - \tau_2) \sinh \omega(\hbar\beta - |\tau_1 - \tau_2|) - \theta(\tau_2 - \tau_1) \sinh \omega(\hbar\beta - |\tau_2 - \tau_1|) - \sinh \omega(\hbar\beta - \tau_1 - \tau_2) \} , \quad (3.391)$$

$$G_{pp}^{(D)}(\tau_1, \tau_2) = \frac{M\hbar\omega}{2 \sinh \hbar\beta\omega} [\cosh \omega(\hbar\beta - |\tau_1 - \tau_2|) + \cosh \omega(\hbar\beta - \tau_1 - \tau_2)] . \quad (3.392)$$

The first correlation function is, of course, the imaginary-time version of the Green function (3.209). Observe the symmetry properties under interchange of the time arguments:

$$G_{xx}^{(D)}(\tau_1, \tau_2) = G_{xx}^{(D)}(\tau_2, \tau_1) , \quad G_{xp}^{(D)}(\tau_1, \tau_2) = -G_{xp}^{(D)}(\tau_2, \tau_1) , \quad (3.393)$$

$$G_{px}^{(D)}(\tau_1, \tau_2) = -G_{px}^{(D)}(\tau_2, \tau_1) , \quad G_{pp}^{(D)}(\tau_1, \tau_2) = G_{pp}^{(D)}(\tau_2, \tau_1) , \quad (3.394)$$

and the identity

$$G_{xp}^{(D)}(\tau_1, \tau_2) = G_{px}^{(D)}(\tau_2, \tau_1). \quad (3.395)$$

In addition, there are the following derivative relations between the Green functions with Dirichlet boundary conditions:

$$G_{xp}^{(D)}(\tau_1, \tau_2) = -iM \frac{\partial}{\partial \tau_1} G_{xx}^{(D)}(\tau_1, \tau_2) = iM \frac{\partial}{\partial \tau_2} G_{xx}^{(D)}(\tau_1, \tau_2), \quad (3.396)$$

$$G_{px}^{(D)}(\tau_1, \tau_2) = iM \frac{\partial}{\partial \tau_1} G_{xx}^{(D)}(\tau_1, \tau_2) = -iM \frac{\partial}{\partial \tau_2} G_{xx}^{(D)}(\tau_1, \tau_2), \quad (3.397)$$

$$G_{pp}^{(D)}(\tau_1, \tau_2) = \hbar M \delta(\tau_1 - \tau_2) - M^2 \frac{\partial^2}{\partial \tau_1 \partial \tau_2} G_{xx}^{(D)}(\tau_1 - \tau_2). \quad (3.398)$$

Note that Eq. (3.385) is a nonlinear alternative to the additive decomposition (3.142) of a Green function with Dirichlet boundary conditions: into Green functions with periodic boundary conditions.

3.13 Particle in Heat Bath

The results of Section 3.8 are the key to understanding the behavior of a quantum-mechanical particle moving through a dissipative medium at a fixed temperature T . We imagine the coordinate $x(t)$ a particle of mass M to be coupled linearly to a *heat bath* consisting of a great number of harmonic oscillators $X_i(\tau)$ ($i = 1, 2, 3, \dots$) with various masses M_i and frequencies Ω_i . The imaginary-time path integral in this heat bath is given by

$$\begin{aligned} (x_b \hbar\beta | x_a 0) &= \prod_i \oint \mathcal{D}X_i(\tau) \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} \mathcal{D}x(\tau) \\ &\times \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \sum_i \left[\frac{M_i}{2} (\dot{X}_i^2 + \Omega_i^2 X_i^2) \right] \right\} \\ &\times \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2 + V(x(\tau)) - \sum_i c_i X_i(\tau) x(\tau) \right] \right\} \times \frac{1}{\prod_i Z_i}, \end{aligned} \quad (3.399)$$

where we have allowed for an arbitrary potential $V(x)$. The partition functions of the individual bath oscillators

$$\begin{aligned} Z_i &\equiv \oint \mathcal{D}X_i(\tau) \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M_i}{2} (\dot{X}_i^2 + \Omega_i^2 X_i^2) \right] \right\} \\ &= \frac{1}{2 \sinh(\hbar\beta\Omega_i/2)} \end{aligned} \quad (3.400)$$

have been divided out, since their thermal behavior is trivial and will be of no interest in the sequel. The path integrals over $X_i(\tau)$ can be performed as in Section 3.1 leading for each oscillator label i to a source expression like (3.246), in which $c_i x(\tau)$ plays the role of a current $j(\tau)$. The result can be written as

$$(x_b \hbar\beta | x_a 0) = \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} \mathcal{D}x(\tau) \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2 + V(x(\tau)) \right] - \frac{1}{\hbar} \mathcal{A}_{\text{bath}}[x] \right\}, \quad (3.401)$$

where $\mathcal{A}_{\text{bath}}[x]$ is a *nonlocal* action for the particle motion generated by the bath

$$\mathcal{A}_{\text{bath}}[x] = -\frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' x(\tau) \alpha(\tau - \tau') x(\tau'). \quad (3.402)$$

The function $\alpha(\tau - \tau')$ is the weighted periodic correlation function (3.251):

$$\begin{aligned} \alpha(\tau - \tau') &= \sum_i c_i^2 \frac{1}{M_i} G_{\Omega_i^2, e}^{\text{p}}(\tau - \tau') \\ &= \sum_i \frac{c_i^2}{2M_i\Omega_i} \frac{\cosh \Omega_i(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\Omega_i\hbar\beta/2)}. \end{aligned} \quad (3.403)$$

Its Fourier expansion has the Matsubara frequencies $\omega_m = 2\pi k_B T / \hbar$

$$\alpha(\tau - \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \alpha_m e^{-i\omega_m(\tau - \tau')}, \quad (3.404)$$

with the coefficients

$$\alpha_m = \sum_i \frac{c_i^2}{M_i} \frac{1}{\omega_m^2 + \omega_i^2}. \quad (3.405)$$

Alternatively, we can write the bath action in the form corresponding to (3.279) as

$$\mathcal{A}_{\text{bath}}[x] = -\frac{1}{2} \int_0^{\hbar\beta} d\tau \int_{-\infty}^{\infty} d\tau' x(\tau) \alpha_0(\tau - \tau') x(\tau'), \quad (3.406)$$

with the weighted nonperiodic correlation function [recall (3.280)]

$$\alpha_0(\tau - \tau') = \sum_i \frac{c_i^2}{2M_i\Omega_i} e^{-\Omega_i|\tau - \tau'|}. \quad (3.407)$$

The bath properties are conveniently summarized by the *spectral density of the bath*

$$\rho_{\text{b}}(\omega') \equiv 2\pi \sum_i \frac{c_i^2}{2M_i\Omega_i} \delta(\omega' - \Omega_i). \quad (3.408)$$

The frequencies Ω_i are by definition positive numbers. The spectral density allows us to express $\alpha_0(\tau - \tau')$ as the spectral integral

$$\alpha_0(\tau - \tau') = \int_0^{\infty} \frac{d\omega'}{2\pi} \rho_{\text{b}}(\omega') e^{-\omega'|\tau - \tau'|}, \quad (3.409)$$

and similarly

$$\alpha(\tau - \tau') = \int_0^{\infty} \frac{d\omega'}{2\pi} \rho_{\text{b}}(\omega') \frac{\cosh \omega'(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega'\hbar\beta/2)}. \quad (3.410)$$

For the Fourier coefficients (3.405), the spectral integral reads

$$\alpha_m = \int_0^\infty \frac{d\omega'}{2\pi} \rho_b(\omega') \frac{2\omega'}{\omega_m^2 + \omega'^2}. \quad (3.411)$$

It is useful to subtract from these coefficients the first term α_0 , and to invert the sign of the remainder making it positive definite. Thus we split

$$\alpha_m = 2 \int_0^\infty \frac{d\omega'}{2\pi} \frac{\rho_b(\omega')}{\omega'} \left(1 - \frac{\omega_m^2}{\omega_m^2 + \omega'^2} \right) = \alpha_0 - g_m. \quad (3.412)$$

Then the Fourier expansion (3.404) separates as

$$\alpha(\tau - \tau') = \alpha_0 \delta^p(\tau - \tau') - g(\tau - \tau'), \quad (3.413)$$

where $\delta^p(\tau - \tau')$ is the periodic δ -function (3.282):

$$\delta^p(\tau - \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} e^{-i\omega_m(\tau - \tau')} = \sum_{n=-\infty}^{\infty} \delta(\tau - \tau' - n\hbar\beta), \quad (3.414)$$

the right-hand sum following from Poisson's summation formula (1.197). The subtracted correlation function

$$g(\tau - \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} g(\omega_m) e^{-i\omega_m(\tau - \tau')}, \quad (3.415)$$

has the coefficients

$$g_m = \sum_i \frac{c_i^2}{M_i} \frac{\omega_m^2}{\omega_m^2 + \Omega_i^2} = \int_0^\infty \frac{d\omega'}{2\pi} \frac{\rho_b(\omega')}{\omega'} \frac{2\omega_m^2}{\omega_m^2 + \omega'^2}. \quad (3.416)$$

The corresponding decomposition of the bath action (3.402) is

$$\mathcal{A}_{\text{bath}}[x] = \mathcal{A}_{\text{loc}} + \mathcal{A}'_{\text{bath}}[x], \quad (3.417)$$

where

$$\mathcal{A}'_{\text{bath}}[x] = \frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' x(\tau) g(\tau - \tau') x(\tau'), \quad (3.418)$$

and

$$\mathcal{A}_{\text{loc}} = -\frac{\alpha_0}{2} \int_0^{\hbar\beta} d\tau x^2(\tau), \quad (3.419)$$

is a local action which can be added to the original action in Eq. (3.401), changing merely the curvature of the potential $V(x)$. Because of this effect, it is useful to introduce a *frequency shift* $\Delta\omega^2$ via the equation

$$M\Delta\omega^2 \equiv -\alpha_0 = -2 \int_0^\infty \frac{d\omega'}{2\pi} \frac{\rho_b(\omega')}{\omega'} = -\sum_i \frac{c_i^2}{M_i \Omega_i^2}. \quad (3.420)$$

Then the local action (3.419) becomes

$$\mathcal{A}_{\text{loc}} = \frac{M}{2} \Delta\omega^2 \int_0^{\hbar\beta} d\tau x^2(\tau). \quad (3.421)$$

This can be absorbed into the potential of the path integral (3.401), yielding a *renormalized potential*

$$V_{\text{ren}}(x) = V(x) + \frac{M}{2} \Delta\omega^2 x^2. \quad (3.422)$$

With the decomposition (3.417), the path integral (3.401) acquires the form

$$(x_b \hbar\beta | x_a 0) = \int_{x(0)=x_a}^{x(\hbar\beta)=x_b} \mathcal{D}x(\tau) \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2 + V_{\text{ren}}(x(\tau)) \right] - \frac{1}{\hbar} \mathcal{A}'_{\text{bath}}[x] \right\}. \quad (3.423)$$

The subtracted correlation function (3.415) has the property

$$\int_0^{\hbar\beta} d\tau g(\tau - \tau') = 0. \quad (3.424)$$

Thus, if we rewrite in (3.418)

$$x(\tau)x(\tau') = \frac{1}{2} \{ x^2(\tau) + x^2(\tau') - [x(\tau) - x(\tau')]^2 \}, \quad (3.425)$$

the first two terms do not contribute, and we remain with

$$\mathcal{A}'_{\text{bath}}[x] = -\frac{1}{4} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' g(\tau - \tau') [x(\tau) - x(\tau')]^2. \quad (3.426)$$

If the oscillator frequencies Ω_i are densely distributed, the function $\rho_b(\omega')$ is continuous. As will be shown later in Eqs. (18.208) and (18.317), an oscillator bath introduces in general a *friction force* into classical equations of motion. If this is to have the usual form $-M\gamma\dot{x}(t)$, the spectral density of the bath must have the approximation

$$\rho_b(\omega') \approx 2M\gamma\omega' \quad (3.427)$$

[see Eqs. (18.208), (18.317)]. This approximation is characteristic for *Ohmic dissipation*. In general, a typical friction force increases with ω only for small frequencies; for larger ω , it decreases again. An often applicable phenomenological approximation is the so-called *Drude form*

$$\rho_b(\omega') \approx 2M\gamma\omega' \frac{\omega_D^2}{\omega_D^2 + \omega'^2}, \quad (3.428)$$

where $1/\omega_D \equiv \tau_D$ is *Drude's relaxation time*. For times much shorter than the Drude time τ_D , there is no dissipation. In the limit of large ω_D , the Drude form describes again Ohmic dissipation.

ref(18.208)
lab(x18.199)
est(18.199)
ref(18.317)
lab(18.396)
est(18.208)

Inserting (3.428) into (3.416), we obtain the Fourier coefficients for Drude dissipation

$$g_m = 2M\gamma\omega_D^2 \int_0^\infty \frac{d\omega}{2\pi} \frac{1}{\omega_D^2 + \omega^2} \frac{2\omega_m^2}{\omega_m^2 + \omega^2} = M|\omega_m|\gamma \frac{\omega_D}{|\omega_m| + \omega_D}. \quad (3.429)$$

It is customary, to factorize

$$g_m \equiv M|\omega_m|\gamma_m, \quad (3.430)$$

so that Drude dissipation corresponds to

$$\gamma_m = \gamma \frac{\omega_D}{|\omega_m| + \omega_D}, \quad (3.431)$$

and Ohmic dissipation to $\gamma_m \equiv \gamma$.

The Drude form of the spectral density gives rise to a frequency shift (3.420)

$$\Delta\omega^2 = -\gamma\omega_D, \quad (3.432)$$

which goes to infinity in the Ohmic limit $\omega_D \rightarrow \infty$.

3.14 Heat Bath of Photons

The heat bath in the last section was a convenient phenomenological tool to reproduce the Ohmic friction observed in many physical systems. In nature, there can be various different sources of dissipation. The most elementary of these is the deexcitation of atoms by radiation, which at zero temperature gives rise to the natural line width of atoms. The photons may form a thermally equilibrated gas, the most famous example being the cosmic black-body radiation which is a gas of the photons of 3 K left over from the big bang 15 billion years ago (and which create a sizable fraction of the blips on our television screens).

The theoretical description is quite simple. We decompose the vector potential $\mathbf{A}(\mathbf{x}, t)$ of electromagnetism into Fourier components of wave vector \mathbf{k}

$$\mathbf{A}(\mathbf{x}, t) = \sum_{\mathbf{k}} c_{\mathbf{k}}(\mathbf{x}) \mathbf{X}_{\mathbf{k}}(t), \quad c_{\mathbf{k}} = \frac{e^{i\mathbf{k}\mathbf{x}}}{\sqrt{2\Omega_{\mathbf{k}}V}}, \quad \sum_{\mathbf{k}} = \int \frac{d^3kV}{(2\pi)^3}. \quad (3.433)$$

The Fourier components $\mathbf{X}_{\mathbf{k}}(t)$ can be considered as a sum of harmonic oscillators of frequency $\Omega_{\mathbf{k}} = c|\mathbf{k}|$, where c is the light velocity. A photon of wave vector \mathbf{k} is a quantum of $\mathbf{X}_{\mathbf{k}}(t)$. A certain number N of photons with the same wave vector can be described as the N th excited state of the oscillator $\mathbf{X}_{\mathbf{k}}(t)$. The statistical sum of these harmonic oscillators led Planck to his famous formula for the energy of black-body radiation for photons in an otherwise empty cavity whose walls have a temperature T . These will form the bath, and we shall now study its effect on the quantum mechanics of a charged point particle. Its coupling to the vector potential is given by the interaction (2.634). Comparison with the coupling to the

heat bath in Eq. (3.399) shows that we simply have to replace $-\sum_i c_i X_i(\tau)x(\tau)$ by $-\sum_{\mathbf{k}} c_{\mathbf{k}} \mathbf{X}_{\mathbf{k}}(\tau)\dot{\mathbf{x}}(\tau)$. The bath action (3.402) takes then the form

$$\mathcal{A}_{\text{bath}}[x] = -\frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \dot{x}^i(\tau) \alpha^{ij}(\mathbf{x}(\tau), \tau; \mathbf{x}(\tau'), \tau') \dot{x}^j(\tau'), \quad (3.434)$$

where $\alpha^{ij}(\mathbf{x}, \tau; \mathbf{x}', \tau')$ is a 3×3 matrix generalization of the correlation function (3.403):

$$\alpha^{ij}(\mathbf{x}, \tau; \mathbf{x}', \tau') = \frac{e^2}{\hbar c^2} \sum_{\mathbf{k}} c_{-\mathbf{k}}(\mathbf{x}) c_{\mathbf{k}}(\mathbf{x}') \langle X_{-\mathbf{k}}^i(\tau) X_{\mathbf{k}}^j(\tau') \rangle. \quad (3.435)$$

We now have to account for the fact that there are two polarization states for each photon, which are transverse to the momentum direction. We therefore introduce a transverse Kronecker symbol

$$T_{\mathbf{k}}^{ij} \equiv (\delta^{ij} - k^i k^j / \mathbf{k}^2) \quad (3.436)$$

and write the correlation function of a single oscillator $X_{-\mathbf{k}}^i(\tau)$ as

$$G_{-\mathbf{k}\mathbf{k}'}^{ij}(\tau - \tau') = \langle \hat{X}_{-\mathbf{k}}^i(\tau) \hat{X}_{\mathbf{k}'}^j(\tau') \rangle = \hbar T_{\mathbf{k}}^{ij} \delta_{\mathbf{k}\mathbf{k}'} G_{\omega^2, \mathbf{e}\mathbf{k}}^{\text{p}}(\tau - \tau'), \quad (3.437)$$

with

$$G_{\omega^2, \mathbf{e}\mathbf{k}}^{\text{p}}(\tau - \tau') \equiv \frac{1}{2\Omega_{\mathbf{k}}} \frac{\cosh \Omega_{\mathbf{k}}(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\Omega_{\mathbf{k}}\hbar\beta/2)}. \quad (3.438)$$

Thus we find

$$\alpha^{ij}(\mathbf{x}, \tau; \mathbf{x}', \tau') = \frac{e^2}{c^2} \int \frac{d^3k}{(2\pi)^3} T_{\mathbf{k}}^{ij} \frac{e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')}}{2\Omega_{\mathbf{k}}} \frac{\cosh \Omega_{\mathbf{k}}(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\Omega_{\mathbf{k}}\hbar\beta/2)}. \quad (3.439)$$

At zero temperature, and expressing $\Omega_{\mathbf{k}} = c|\mathbf{k}|$, this simplifies to

$$\alpha^{ij}(\mathbf{x}, \tau; \mathbf{x}', \tau') = \frac{e^2}{c^3} \int \frac{d^3k}{(2\pi)^3} T_{\mathbf{k}}^{ij} \frac{e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}') - c|\mathbf{k}||\tau - \tau'|}}{2|\mathbf{k}|}. \quad (3.440)$$

Forgetting for a moment the transverse Kronecker symbol and the prefactor e^2/c^2 , the integral yields

$$G_e^R(\mathbf{x}, \tau; \mathbf{x}', \tau') = \frac{1}{4\pi^2 c^2} \frac{1}{(\tau - \tau')^2 + (\mathbf{x} - \mathbf{x}')^2 / c^2}, \quad (3.441)$$

which is the imaginary-time version of the well-known retarded Green function used in electromagnetism. If the system is small compared to the average wavelengths in the bath we can neglect the retardation and omit the term $(\mathbf{x} - \mathbf{x}')^2 / c^2$. In the finite-temperature expression (3.440) this amounts to neglecting the \mathbf{x} -dependence.

The transverse Kronecker symbol can then be averaged over all directions of the wave vector and yields simply $2\delta^{ij}/3$, and we obtain the approximate function

$$\alpha^{ij}(\mathbf{x}, \tau; \mathbf{x}', \tau') = \frac{2e^2}{3c^2} \delta^{ij} \frac{1}{2\pi c^2} \int \frac{d\omega}{2\pi} \omega \frac{\cosh \omega(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\omega\hbar\beta/2)}. \quad (3.442)$$

This has the generic form (3.410) with the spectral function of the photon bath

$$\rho_{\text{pb}}(\omega') = \frac{e^2}{3c^2\pi} \omega'. \quad (3.443)$$

This has precisely the Ohmic form (3.427), but there is now an important difference: the bath action (3.434) contains now the time derivatives of the paths $\mathbf{x}(\tau)$. This gives rise to an extra factor ω'^2 in (3.427), so that we may define a spectral density for the photon bath:

$$\rho_{\text{pb}}(\omega') \approx 2M\gamma\omega'^3, \quad \gamma = \frac{e^2}{6c^2\pi M}. \quad (3.444)$$

In contrast to the usual friction constant γ in the previous section, this has the dimension 1/frequency.

3.15 Harmonic Oscillator in Ohmic Heat Bath

For a harmonic oscillator in an Ohmic heat bath, the partition function can be calculated as follows. Setting

$$V_{\text{ren}}(x) = \frac{M}{2} \omega^2 x^2, \quad (3.445)$$

the Fourier decomposition of the action (3.423) reads

$$\mathcal{A}_e = \frac{M\hbar}{k_B T} \left\{ \frac{\omega^2}{2} x_0^2 + \sum_{m=1}^{\infty} [\omega_m^2 + \omega^2 + \omega_m \gamma_m] |x_m|^2 \right\}. \quad (3.446)$$

The harmonic potential is the full renormalized potential (3.422). Performing the Gaussian integrals using the measure (2.447), we obtain the partition function for the damped harmonic oscillator of frequency ω [compare (2.408)]

$$Z_{\omega}^{\text{damp}} = \frac{k_B T}{\hbar\omega} \left\{ \prod_{m=1}^{\infty} \left[\frac{\omega_m^2 + \omega^2 + \omega_m \gamma_m}{\omega_m^2} \right] \right\}^{-1}. \quad (3.447)$$

For the Drude dissipation (3.429), this can be written as

$$Z_{\omega}^{\text{damp}} = \frac{k_B T}{\hbar\omega} \prod_{m=1}^{\infty} \frac{\omega_m^2 (\omega_m + \omega_D)}{\omega_m^3 + \omega_m^2 \omega_D + \omega_m (\omega^2 + \gamma \omega_D) + \omega_D \omega^2}. \quad (3.448)$$

Let w_1, w_2, w_3 be the roots of the cubic equation

$$w^3 - w^2 \omega_D + w(\omega^2 + \gamma \omega_D) - \omega^2 \omega_D = 0. \quad (3.449)$$

Then we can rewrite (3.448) as

$$Z_\omega^{\text{damp}} = \frac{k_B T}{\hbar \omega} \prod_{m=1}^{\infty} \frac{\omega_m}{\omega_m + w_1} \frac{\omega_m}{\omega_m + w_2} \frac{\omega_m}{\omega_m + w_3} \frac{\omega_m + \omega_D}{\omega_m}. \quad (3.450)$$

Using the product representation of the Gamma function⁸

$$\Gamma(z) = \lim_{n \rightarrow \infty} \frac{n^z}{z} \prod_{m=1}^n \frac{m}{m+z} \quad (3.451)$$

and the fact that

$$w_1 + w_2 + w_3 - \omega_D = 0, \quad w_1 w_2 w_3 = \omega^2 \omega_D, \quad (3.452)$$

the partition function (3.450) becomes

$$Z_\omega^{\text{damp}} = \frac{1}{2\pi} \frac{\omega}{\omega_1} \frac{\Gamma(w_1/\omega_1) \Gamma(w_2/\omega_1) \Gamma(w_3/\omega_1)}{\Gamma(\omega_D/\omega_1)}, \quad (3.453)$$

where $\omega_1 = 2\pi k_B T / \hbar$ is the first Matsubara frequency, such that $w_i/\omega_1 = w_i \beta / 2\pi$.

In the Ohmic limit $\omega_D \rightarrow \infty$, the roots w_1, w_2, w_3 reduce to

$$w_1 = \gamma/2 + i\delta, \quad w_2 = \gamma/2 - i\delta, \quad w_3 = \omega_D - \gamma, \quad (3.454)$$

with

$$\delta \equiv \sqrt{\omega^2 - \gamma^2/4}, \quad (3.455)$$

and (3.453) simplifies further to

$$Z_\omega^{\text{damp}} = \frac{1}{2\pi} \frac{\omega}{\omega_1} \Gamma(w_1/\omega_1) \Gamma(w_2/\omega_1). \quad (3.456)$$

For vanishing friction, the roots w_1 and w_2 become simply $w_1 = i\omega$, $w_2 = -i\omega$, and the formula⁹

$$\Gamma(1-z)\Gamma(z) = \frac{\pi}{\sin \pi z} \quad (3.457)$$

can be used to calculate

$$\Gamma(i\omega/\omega_1)\Gamma(-i\omega/\omega_1) = \frac{\omega_1}{\omega} \frac{\pi}{\sinh(\pi\omega/\omega_1)} = \frac{\omega_1}{\omega} \frac{\pi}{\sinh(\omega\hbar/2k_B T)}, \quad (3.458)$$

showing that (3.453) goes properly over into the partition function (3.217) of the undamped harmonic oscillator.

The free energy of the system is

$$F(T) = -k_B T [\log(\omega/2\pi\omega_1) - \log \Gamma(\omega_D/\omega_1) + \log \Gamma(w_1/\omega_1) + \log \Gamma(w_2/\omega_1) + \log \Gamma(w_3/\omega_1)]. \quad (3.459)$$

⁸I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 8.322.

⁹*ibid.*, Formula 8.334.3.

Using the large- z behavior of $\log \Gamma(z)$ ¹⁰

$$\log \Gamma(z) = \left(z - \frac{1}{2}\right) \log z - z + \frac{1}{2} \log 2\pi + \frac{1}{12z} - \frac{1}{360z^3} - \mathcal{O}(1/z^5), \quad (3.460)$$

we find the free energy at low temperature

$$F(T) \sim E_0 - \left(\frac{1}{w_1} + \frac{1}{w_2} + \frac{1}{w_3} - \frac{\omega^2}{w_1 w_2 w_3}\right) \frac{\pi}{6\hbar} (k_B T)^2 = E_0 - \frac{\gamma\pi}{6\omega^2\hbar} (k_B T)^2, \quad (3.461)$$

where

$$E_0 = -\frac{\hbar}{2\pi} [w_1 \log(w_1/\omega_D) + w_2 \log(w_2/\omega_D) + w_3 \log(w_3/\omega_D)] \quad (3.462)$$

is the ground state energy.

For small friction, this reduces to

$$E_0 = \frac{\hbar\omega}{2} + \frac{\gamma}{2\pi} \log \frac{\omega_D}{\omega} - \frac{\gamma^2}{16\omega} \left(1 + \frac{4\omega}{\pi\omega_D}\right) + \mathcal{O}(\gamma^3). \quad (3.463)$$

The T^2 -behavior of $F(T)$ in Eq. (3.461) is typical for Ohmic dissipation.

At zero temperature, the Matsubara frequencies $\omega_m = 2\pi m k_B T / \hbar$ move arbitrarily close together, so that Matsubara sums become integrals according to the rule

$$\frac{1}{\hbar\beta} \sum_m \xrightarrow{T \rightarrow 0} \int_0^\infty \frac{d\omega_m}{2\pi}. \quad (3.464)$$

Applying this limiting procedure to the logarithm of the product formula (3.448), the ground state energy can also be written as an integral

$$E_0 = \frac{\hbar}{2\pi} \int_0^\infty d\omega_m \log \left[\frac{\omega_m^3 + \omega_m^2 \omega_D + \omega_m (\omega^2 + \gamma \omega_D) + \omega_D \omega^2}{\omega_m^2 (\omega_m + \omega_D)} \right], \quad (3.465)$$

which shows that the energy E_0 increases with the friction coefficient γ .

It is instructive to calculate the density of states defined in (1.583). Inverting the Laplace transform (1.582), we have to evaluate

$$\rho(\varepsilon) = \frac{1}{2\pi i} \int_{\eta-i\infty}^{\eta+i\infty} d\beta e^{i\varepsilon\beta} Z_\omega^{\text{damp}}(\beta), \quad (3.466)$$

where η is an infinitesimally small positive number. In the absence of friction, the integral over $Z_\omega(\beta) = \sum_{n=0}^\infty e^{-\beta\hbar\omega(n+1/2)}$ yields

$$\rho(\varepsilon) = \sum_{n=0}^\infty \delta(\varepsilon - (n+1/2)\hbar\omega). \quad (3.467)$$

In the presence of friction, we expect the sharp δ -function spikes to be broadened. The calculation is done as follows: The vertical line of integration in the complex β -plane in (3.466) is moved all the way to the left, thereby picking up the poles

Figure 3.5 Poles in complex β -plane of Fourier integral (3.466) coming from the Gamma functions of (3.453)

of the Gamma functions which lie at negative integer values of $w_i\beta/2\pi$. From the representation of the Gamma function¹¹

$$\Gamma(z) = \int_1^\infty dt t^{z-1} e^{-t} + \sum_{n=0}^{\infty} \frac{(-1)^n}{n!(z+n)} \quad (3.468)$$

we see the size of the residues. Thus we obtain the sum

$$\rho(\varepsilon) = \frac{1}{\omega} \sum_{n=1}^{\infty} \sum_{i=1}^3 R_{n,i} e^{-2\pi n\varepsilon/w_i}, \quad (3.469)$$

$$R_{n,1} = \frac{\omega}{w_1^2} \frac{(-1)^{n-1}}{(n-1)!} \frac{\Gamma(-nw_2/w_1)\Gamma(-nw_3/w_1)}{\Gamma(-n\omega_D/w_1)}, \quad (3.470)$$

with analogous expressions for $R_{n,2}$ and $R_{n,3}$. The sum can be done numerically and yields the curves shown in Fig. 3.6 for typical underdamped and overdamped situations. There is an isolated δ -function at the ground state energy E_0 of (3.462) which is not widened by the friction. Right above E_0 , the curve continues from a finite value $\rho(E_0 + 0) = \gamma\pi/6\omega^2$ determined by the first expansion term in (3.461).

3.16 Harmonic Oscillator in Photon Heat Bath

It is straightforward to extend this result to a photon bath where the spectral density is given by (3.444) and (3.471) becomes

$$Z_\omega^{\text{damp}} = \frac{k_B T}{\hbar\omega} \left\{ \prod_{m=1}^{\infty} \left[\frac{\omega_m^2 + \omega^2 + \omega_m^3 \gamma}{\omega_m^2} \right] \right\}^{-1}, \quad (3.471)$$

¹⁰ *ibid.*, Formula 8.327.

¹¹ *ibid.*, Formula 8.314.

Figure 3.6 Density of states for weak and strong damping in natural units. On the left, the parameters are $\gamma/\omega = 0.2$, $\omega_D/\omega = 10$, on the right $\gamma/\omega = 5$, $\omega_D/\omega = 10$. For more details see Hanke and Zwerger in Notes and References.

with $\gamma = e^2/6c^2\pi M$. The power of ω_m accompanying the friction constant is increased by two units. Adding a Drude correction for the high-frequency behavior we replace γ by $\omega_m/(\omega_m + \omega_D)$ and obtain instead of (3.448)

$$Z_\omega^{\text{damp}} = \frac{k_B T}{\hbar\omega} \prod_{m=1}^{\infty} \frac{\omega_m^2(\omega_m + \omega_D)(1 + \gamma\omega_D)}{\omega_m^3(1 + \gamma\omega_D) + \omega_m^2\omega_D + \omega_m\omega^2 + \omega_D\omega^2}. \quad (3.472)$$

The resulting partition function has again the form (3.453), except that w_{123} are the solutions of the cubic equation

$$w^3(1 + \gamma\omega_D) - w^2\omega_D + w\omega^2 - \omega^2\omega_D = 0. \quad (3.473)$$

Since the electromagnetic coupling is small, we can solve this equation to lowest order in γ . If we also assume ω_D to be large compared to ω , we find the roots

$$w_1 \approx \gamma_{\text{pb}}^{\text{eff}}/2 + i\omega, \quad w_2 \approx \gamma_{\text{pb}}^{\text{eff}}/2 - i\omega, \quad w_3 \approx \omega_D/(1 + \gamma_{\text{pb}}^{\text{eff}}\omega_D/\omega^2), \quad (3.474)$$

where we have introduced an effective friction constant of the photon bath

$$\gamma_{\text{pb}}^{\text{eff}} = \frac{e^2}{6c^2\pi M}\omega^2, \quad (3.475)$$

which has the dimension of a frequency, just as the usual friction constant γ in the previous heat bath equations (3.454).

3.17 Perturbation Expansion of Anharmonic Systems

If a harmonic system is disturbed by an additional anharmonic potential $V(x)$, to be called *interaction*, the path integral can be solved exactly only in exceptional cases. These will be treated in Chapters 8, 13, and 14. For sufficiently smooth and small potentials $V(x)$, it is always possible to expand the full partition in powers of the interaction strength. The result is the so-called *perturbation series*. Unfortunately, it only renders reliable numerical results for very small $V(x)$ since, as we shall prove

in Chapter 17, the expansion coefficients grow for large orders k like $k!$, making the series strongly divergent. The can only be used for extremely small perturbations. Such expansions are called *asymptotic* (more in Subsection 17.10.1). For this reason we are forced to develop a more powerful technique of studying anharmonic systems in Chapter 5. It combines the perturbation series with a variational approach and will yield very accurate energy levels up to arbitrarily large interaction strengths. It is therefore worthwhile to find the formal expansion in spite of its divergence.

Consider the quantum-mechanical amplitude

$$(x_b t_b | x_a t_a) = \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{x}^2 - M \frac{\omega^2}{2} x^2 - V(x) \right] \right\}, \quad (3.476)$$

and expand the integrand in powers of $V(x)$, which leads to the series

$$\begin{aligned} (x_b t_b | x_a t_a) &= \int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \left[1 - \frac{i}{\hbar} \int_{t_a}^{t_b} dt V(x(t)) \right. \\ &\quad - \frac{1}{2! \hbar^2} \int_{t_a}^{t_b} dt_2 V(x(t_2)) \int_{t_a}^{t_b} dt_1 V(x(t_1)) \\ &\quad + \frac{i}{3! \hbar^3} \int_{t_a}^{t_b} dt_3 V(x(t_3)) \int_{t_a}^{t_b} dt_2 V(x(t_2)) \int_{t_a}^{t_b} dt_1 V(x(t_1)) + \dots \left. \right] \\ &\quad \times \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{x}^2 - \omega^2 x^2) \right]. \end{aligned} \quad (3.477)$$

If we decompose the path integral in the n th term into a product (2.4), the expansion can be rewritten as

$$\begin{aligned} (x_b t_b | x_a t_a) &= (x_b t_b | x_a t_a) - \frac{i}{\hbar} \int_{t_a}^{t_b} dt_1 \int dx_1 (x_b t_b | x_1 t_1) V(x_1) (x_1 t_1 | x_a t_a) \\ &\quad - \frac{1}{2! \hbar^2} \int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_b} dt_1 \int dx_1 dx_2 (x_b t_b | x_2 t_2) V(x_2) (x_2 t_2 | x_1 t_1) V(x_1) (x_1 t_1 | x_a t_a) + \dots \end{aligned} \quad (3.478)$$

A similar expansion can be given for the Euclidean path integral of a partition function

$$Z = \oint \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) + V(x) \right] \right\}, \quad (3.479)$$

where we obtain

$$\begin{aligned} Z &= \int \mathcal{D}x \left[1 - \frac{1}{\hbar} \int_0^{\hbar\beta} d\tau V(x(\tau)) + \frac{1}{2! \hbar^2} \int_0^{\hbar\beta} d\tau_2 V(x(\tau_2)) \int_0^{\hbar\beta} d\tau_1 V(x(\tau_1)) \right. \\ &\quad - \frac{1}{3! \hbar^3} \int_0^{\hbar\beta} d\tau_3 V(x(\tau_3)) \int_0^{\hbar\beta} d\tau_2 V(x(\tau_2)) \int_0^{\hbar\beta} d\tau_1 V(x(\tau_1)) + \dots \left. \right] \\ &\quad \times \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} dt \left[\frac{M}{2} \dot{x}^2 + M \frac{\omega^2}{2} x^2 \right] \right\}. \end{aligned} \quad (3.480)$$

The individual terms are obviously expectation values of powers of the Euclidean interaction

$$\mathcal{A}_{\text{int,e}} \equiv \int_0^{\hbar\beta} d\tau V(x(\tau)), \quad (3.481)$$

calculated within the harmonic-oscillator partition function Z_ω . The expectation values are defined by

$$\langle \dots \rangle_\omega \equiv Z_\omega^{-1} \int \mathcal{D}x \dots \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) \right] \right\}. \quad (3.482)$$

With these, the perturbation series can be written in the form

$$Z = \left(1 - \frac{1}{\hbar} \langle \mathcal{A}_{\text{int},e} \rangle_\omega + \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_\omega - \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int},e}^3 \rangle_\omega + \dots \right) Z_\omega. \quad (3.483)$$

As we shall see immediately, it is preferable to resum the prefactor into an exponential of a series

$$\begin{aligned} & 1 - \frac{1}{\hbar} \langle \mathcal{A}_{\text{int},e} \rangle_\omega + \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_\omega - \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int},e}^3 \rangle_\omega + \dots \\ &= \exp \left\{ -\frac{1}{\hbar} \langle \mathcal{A}_{\text{int},e} \rangle_\omega + \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_{\omega,c} - \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int},e}^3 \rangle_{\omega,c} + \dots \right\}. \end{aligned} \quad (3.484)$$

The expectation values $\langle \rangle_{\omega,c}$ are called *cumulants*. They are related to the original expectation values by the *cumulant expansion*:¹²

$$\langle \mathcal{A}_{\text{int},e}^2 \rangle_{\omega,c} \equiv \langle \mathcal{A}_{\text{int},e}^2 \rangle_\omega - \langle \mathcal{A}_{\text{int},e} \rangle_\omega^2 \quad (3.485)$$

$$= \langle [\mathcal{A}_{\text{int},e} - \langle \mathcal{A}_{\text{int},e} \rangle_\omega]^2 \rangle_\omega,$$

$$\langle \mathcal{A}_{\text{int},e}^3 \rangle_{\omega,c} \equiv \langle \mathcal{A}_{\text{int},e}^3 \rangle_\omega - 3 \langle \mathcal{A}_{\text{int},e}^2 \rangle_\omega \langle \mathcal{A}_{\text{int},e} \rangle_\omega + 2 \langle \mathcal{A}_{\text{int},e} \rangle_\omega^3 \quad (3.486)$$

$$= \langle [\mathcal{A}_{\text{int},e} - \langle \mathcal{A}_{\text{int},e} \rangle_\omega]^3 \rangle_\omega,$$

$$\vdots \quad .$$

The cumulants contribute directly to the free energy $F = -(1/\beta) \log Z$. From (3.484) and (3.483) we conclude that the anharmonic potential $V(x)$ shifts the free energy of the harmonic oscillator $F_\omega = (1/\beta) \log[2 \sinh(\hbar\beta\omega/2)]$ by

$$\Delta F = \frac{1}{\beta} \left(\frac{1}{\hbar} \langle \mathcal{A}_{\text{int},e} \rangle_\omega - \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_{\omega,c} + \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int},e}^3 \rangle_{\omega,c} + \dots \right). \quad (3.487)$$

Whereas the original expectation values $\langle \mathcal{A}_{\text{int},e}^n \rangle_\omega$ grow for large β with the n th power of β , due to contributions of n disconnected diagrams of first order in g which are integrated independently over τ from 0 to $\hbar\beta$, the cumulants $\langle \mathcal{A}_{\text{int},e}^n \rangle_{\omega,c}$ are proportional to β , thus ensuring that the free energy F has a finite limit, the ground state energy E_0 . In comparison with the ground state energy of the unperturbed harmonic system, the energy E_0 is shifted by

$$\Delta E_0 = \lim_{\beta \rightarrow \infty} \frac{1}{\beta} \left(\frac{1}{\hbar} \langle \mathcal{A}_{\text{int},e} \rangle_\omega - \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_{\omega,c} + \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int},e}^3 \rangle_{\omega,c} + \dots \right). \quad (3.488)$$

¹²Note that the subtracted expressions in the second lines of these equations are particularly simple only for the lowest two cumulants given here.

There exists a simple functional formula for the perturbation expansion of the partition function in terms of the generating functional $Z_\omega[j]$ of the unperturbed harmonic system. Adding a source term into the action of the path integral (3.479), we define the generating functional of the interacting theory:

$$Z[j] = \oint \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) + V(x) - jx \right] \right\}. \quad (3.489)$$

The interaction can be brought outside the path integral in the form

$$Z[j] = e^{-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau V(\delta/\delta j(\tau))} Z_\omega[j]. \quad (3.490)$$

The interacting partition function is obviously

$$Z = Z[0]. \quad (3.491)$$

Indeed, after inserting on the right-hand side the explicit path integral expression for $Z[j]$ from (3.236):

$$Z_\omega[j] = \int \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) - jx \right] \right\}, \quad (3.492)$$

and expanding the exponential in the prefactor

$$\begin{aligned} e^{-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau V(\delta/\delta j(\tau))} &= 1 - \frac{1}{\hbar} \int_0^{\hbar\beta} d\tau V(\delta/\delta j(\tau)) \\ &+ \frac{1}{2!\hbar^2} \int_0^{\hbar\beta} d\tau_2 V(\delta/\delta j(\tau_2)) \int_0^{\hbar\beta} d\tau_1 V(\delta/\delta j(\tau_1)) \\ &- \frac{1}{3!\hbar^3} \int_0^{\hbar\beta} d\tau_3 V(\delta/\delta j(\tau_3)) \int_0^{\hbar\beta} d\tau_2 V(\delta/\delta j(\tau_2)) \int_0^{\hbar\beta} d\tau_1 V(\delta/\delta j(\tau_1)) + \dots, \end{aligned} \quad (3.493)$$

the functional derivatives of $Z[j]$ with respect to the source $j(\tau)$ generate inside the path integral precisely the expansion (3.483), whose cumulants lead to formula (3.487) for the shift in the free energy.

Before continuing, let us mention that the partition function (3.479) can, of course, be viewed as a generating functional for the calculation of the expectation values of the action and its powers. We simply have to form the derivatives with respect to \hbar^{-1} :

$$\langle \mathcal{A}^n \rangle = Z^{-1} \frac{\partial^n}{\partial \hbar^{-1n}} Z_\omega[j] \Big|_{\hbar^{-1}=0}. \quad (3.494)$$

For a harmonic oscillator where Z is given by (3.245), this yields

$$\langle \mathcal{A} \rangle = \lim_{\hbar \rightarrow \infty} Z_\omega^{-1} \hbar^2 \frac{\partial}{\partial \hbar} Z_\omega = \lim_{\hbar \rightarrow \infty} \hbar \frac{\hbar\omega\beta}{2 \sinh \hbar\omega\beta/2} = 0. \quad (3.495)$$

The same result is, incidentally, obtained by calculating the expectation value of the action with analytic regularization:

$$\langle \dot{x}^2(\tau) \rangle_\omega + \omega^2 \langle x^2(\tau) \rangle_\omega = \int \frac{d\omega'}{2\pi} \frac{\omega'^2}{\omega'^2 + \omega^2} + \int \frac{d\omega'}{2\pi} \frac{\omega^2}{\omega'^2 + \omega^2} = \int \frac{d\omega'}{2\pi} = 0. \quad (3.496)$$

The integral vanishes by Veltman's rule (2.508).

3.18 Rayleigh-Schrödinger and Brillouin-Wigner Perturbation Expansion

The expectation values in formula (3.487) can be evaluated by means of the so-called *Rayleigh-Schrödinger perturbation expansion*, also referred to as *old-fashioned perturbation expansion*. This expansion is particularly useful if the potential $V(x)$ is not a polynomial in x . Examples are $V(x) = \delta(x)$ and $V(x) = 1/x$. In these two cases the perturbation expansions can be summed to all orders, as will be shown for the first example in Section 9.5. For the second example the reader is referred to the literature.¹³ We shall explicitly demonstrate the procedure for the ground state and the excited energies of an anharmonic oscillator. Later we shall also give expansions for scattering amplitudes.

To calculate the free-energy shift ΔF in Eq. (3.487) to first order in $V(x)$, we need the expectation

$$\langle \mathcal{A}_{\text{int},e} \rangle_\omega \equiv Z_\omega^{-1} \int_0^{\hbar\beta} d\tau_1 \int dx dx_1 (x | \hbar\beta | x_1 \tau_1)_\omega V(x_1) (x_1 \tau_1 | x 0)_\omega. \quad (3.497)$$

The time evolution amplitude on the right describes the temporal development of the harmonic oscillator located initially at the point x , from the imaginary time 0 up to τ_1 . At the time τ_1 , the state is subject to the interaction depending on its position $x_1 = x(\tau_1)$ with the amplitude $V(x_1)$. After that, the state is carried to the final state at the point x by the other time evolution amplitude.

To second order we have to calculate the expectation in $V(x)$:

$$\begin{aligned} \frac{1}{2} \langle \mathcal{A}_{\text{int},e}^2 \rangle_\omega &\equiv Z_\omega^{-1} \int_0^{\hbar\beta} d\tau_2 \int_0^{\hbar\beta} d\tau_1 \int dx dx_2 dx_1 (x | \hbar\beta | x_2 \tau_2)_\omega V(x_2) \\ &\quad \times (x_2 \tau_2 | x_1 \tau_1)_\omega V(x_1) (x_1 \tau_1 | x 0)_\omega. \end{aligned} \quad (3.498)$$

The integration over τ_1 is taken only up to τ_2 since the contribution with $\tau_1 > \tau_2$ would merely render a factor 2.

The explicit evaluation of the integrals is facilitated by the spectral expansion (2.300). The time evolution amplitude at imaginary times is given in terms of the eigenstates $\psi_n(x)$ of the harmonic oscillator with the energy $E_n = \hbar\omega(n + 1/2)$:
ref(2.300) (2.300). The time evolution amplitude at imaginary times is given in terms of the lab(x2.206)eigenstates $\psi_n(x)$ of the harmonic oscillator with the energy $E_n = \hbar\omega(n + 1/2)$:
 est(2.206)

$$(x_b \tau_b | x_a \tau_a)_\omega = \sum_{n=0}^{\infty} \psi_n(x_b) \psi_n^*(x_a) e^{-E_n(\tau_b - \tau_a)/\hbar}. \quad (3.499)$$

The same type of expansion exists also for the real-time evolution amplitude. This leads to the Rayleigh-Schrödinger perturbation expansion for the energy shifts of all excited states, as we now show.

The amplitude can be projected onto the eigenstates of the harmonic oscillator. For this, the two sides are multiplied by the harmonic wave functions $\psi_n^*(x_b)$ and

¹³M.J. Goovaerts and J.T. Devreese, *J. Math. Phys.* 13, 1070 (1972).

$\psi_n(x_a)$ of quantum number n and integrated over x_b and x_a , respectively, resulting in the expansion

$$\int dx_b dx_a \psi_n^*(x_b)(x_b t_b | x_a t_a) \psi_n(x_a) = \int dx_b dx_a \psi_n^*(x_b)(x_b t_b | x_a t_a)_\omega \psi_n(x_a) \times \left(1 + \frac{i}{\hbar} \langle n | \mathcal{A}_{\text{int}} | n \rangle_\omega - \frac{1}{2! \hbar^2} \langle n | \mathcal{A}_{\text{int}}^2 | n \rangle_\omega - \frac{i}{3! \hbar^3} \langle n | \mathcal{A}_{\text{int}}^3 | n \rangle_\omega + \dots \right), \quad (3.500)$$

with the interaction

$$\mathcal{A}_{\text{int}} \equiv - \int_{t_a}^{t_b} dt V(x(t)). \quad (3.501)$$

The expectation values are defined by

$$\langle n | \dots | n \rangle_\omega \equiv Z_{\text{QM},\omega,n}^{-1} \int dx_b dx_a \psi_n^*(x_b) \left(\int_{x(t_a)=x_a}^{x(t_b)=x_b} \mathcal{D}x \dots e^{i\mathcal{A}_\omega/\hbar} \right) \psi_n(x_a), \quad (3.502)$$

where

$$Z_{\text{QM},\omega,n} \equiv e^{-i\omega(n+1/2)(t_b-t_a)} \quad (3.503)$$

is the projection of the quantum-mechanical partition function of the harmonic oscillator

$$Z_{\text{QM},\omega} = \sum_{n=0}^{\infty} e^{-i\omega(n+1/2)(t_b-t_a)}$$

[see (2.42)] onto the n th excited state.

The expectation values are calculated as in (3.497), (3.498). To first order in $V(x)$, one has ref(2.42)
lab(2.24)
est(2.26)

$$\langle n | \mathcal{A}_{\text{int}} | n \rangle_\omega \equiv -Z_{\text{QM},\omega,n}^{-1} \int_{t_a}^{t_b} dt_1 \int dx_b dx_a dx_1 \psi_n^*(x_b)(x_b t_b | x_1 t_1)_\omega \times V(x_1)(x_1 t_1 | x_a t_a)_\omega \psi_n(x_a). \quad (3.504)$$

The time evolution amplitude on the right-hand side describes the temporal development of the initial state $\psi_n(x_a)$ from the time t_a to the time t_1 , where the interaction takes place with an amplitude $-V(x_1)$. After that, the time evolution amplitude on the left-hand side carries the state to $\psi_n^*(x_b)$.

To second order in $V(x)$, the expectation value is given by the double integral

$$\frac{1}{2} \langle n | \mathcal{A}_{\text{int}}^2 | n \rangle_\omega \equiv Z_{\text{QM},\omega,n}^{-1} \int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_2} dt_1 \int dx_b dx_a dx_2 dx_1 \times \psi_n^*(x_b)(x_b t_b | x_2 t_2)_\omega V(x_2)(x_2 t_2 | x_1 t_1)_\omega V(x_1)(x_1 t_1 | x_a t_a)_\omega \psi_n(x_a). \quad (3.505)$$

As in (3.498), the integral over t_1 ends at t_2 .

By analogy with (3.484), we resum the corrections in (3.500) to bring them into the exponent:

$$1 + \frac{i}{\hbar} \langle n | \mathcal{A}_{\text{int}} | n \rangle_\omega - \frac{1}{2! \hbar^2} \langle n | \mathcal{A}_{\text{int}}^2 | n \rangle_\omega - \frac{i}{3! \hbar^3} \langle n | \mathcal{A}_{\text{int}}^3 | n \rangle_\omega + \dots \quad (3.506) \\ = \exp \left\{ \frac{i}{\hbar} \langle n | \mathcal{A}_{\text{int}} | n \rangle_\omega - \frac{1}{2! \hbar^2} \langle n | \mathcal{A}_{\text{int}}^2 | n \rangle_{\omega,c} - \frac{i}{3! \hbar^3} \langle n | \mathcal{A}_{\text{int}}^3 | n \rangle_{\omega,c} + \dots \right\}.$$

The cumulants in the exponent are

$$\begin{aligned}\langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega,c} &\equiv \langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega} - \langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega}^2 \\ &= \langle n|[\mathcal{A}_{\text{int}} - \langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega}]^2|n\rangle_{\omega},\end{aligned}\quad (3.507)$$

$$\begin{aligned}\langle n|\mathcal{A}_{\text{int}}^3|n\rangle_{\omega,c} &\equiv \langle n|\mathcal{A}_{\text{int}}^3|n\rangle_{\omega} - 3\langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega}\langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega} + 2\langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega}^3 \\ &= \langle n|[\mathcal{A}_{\text{int}} - \langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega}]^3|n\rangle_{\omega},\end{aligned}\quad (3.508)$$

\vdots

\cdot

From (3.506), we obtain the energy shift of the n th oscillator energy

$$\begin{aligned}\Delta E_n = \lim_{t_b-t_a \rightarrow \infty} \frac{i\hbar}{t_b-t_a} \left\{ \frac{i}{\hbar} \langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega} - \frac{1}{2!\hbar^2} \langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega,c} \right. \\ \left. - \frac{i}{3!\hbar^3} \langle n|\mathcal{A}_{\text{int}}^3|n\rangle_{\omega,c} + \dots \right\},\end{aligned}\quad (3.509)$$

which is a generalization of formula (3.488) which was valid only for the ground state energy. At $n = 0$, the new formula goes over into (3.488), after the usual analytic continuation of the time variable.

The cumulants can be evaluated further with the help of the real-time version of the spectral expansion (3.499):

$$(x_b t_b | x_a t_a)_{\omega} = \sum_{n=0}^{\infty} \psi_n(x_b) \psi_n^*(x_a) e^{-iE_n(t_b-t_a)/\hbar}.\quad (3.510)$$

To first order in $V(x)$, it leads to

$$\langle n|\mathcal{A}_{\text{int}}|n\rangle_{\omega} \equiv - \int_{t_a}^{t_b} dt \int dx \psi_n^*(x) V(x) \psi_n(x) \equiv -(t_b - t_a) V_{nn}.\quad (3.511)$$

To second order in $V(x)$, it yields

$$\begin{aligned}\frac{1}{2} \langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega} &\equiv Z_{\text{QM},\omega,n}^{-1} \int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_2} dt_1 \\ &\times \sum_k e^{-iE_n(t_b-t_2)/\hbar - iE_k(t_2-t_1)/\hbar - iE_n(t_1-t_a)/\hbar} V_{nk} V_{kn}.\end{aligned}\quad (3.512)$$

The right-hand side can also be written as

$$\int_{t_a}^{t_b} dt_2 \int_{t_a}^{t_2} dt_1 \sum_k e^{i(E_n - E_k)t_2/\hbar + i(E_k - E_n)t_1/\hbar} V_{nk} V_{kn}\quad (3.513)$$

and becomes, after the time integrations,

$$- \sum_k \frac{V_{nk} V_{kn}}{E_k - E_n} \left\{ i\hbar(t_b - t_a) - \frac{\hbar^2}{E_n - E_k} \left[e^{i(E_n - E_k)(t_b - t_a)/\hbar} - 1 \right] \right\}.\quad (3.514)$$

As it stands, the sum makes sense only for the $E_k \neq E_n$ -terms. In these, the second term in the curly brackets can be neglected in the limit of large time differences $t_b - t_a$. The term with $E_k = E_n$ must be treated separately by doing the integral directly in (3.513). This yields

$$V_{nn}V_{nn}\frac{(t_b - t_a)^2}{2}, \quad (3.515)$$

so that

$$\frac{1}{2}\langle n|\mathcal{A}_{\text{int}}^2|n\rangle_\omega = -\sum_{m \neq n} \frac{V_{nm}V_{mn}}{E_m - E_n} i\hbar(t_b - t_a) + V_{nn}V_{nn}\frac{(t_b - t_a)^2}{2}. \quad (3.516)$$

The same result could have been obtained without the special treatment of the $E_k = E_n$ -term by introducing artificially an infinitesimal energy difference $E_k - E_n = \epsilon$ in (3.514), and by expanding the curly brackets in powers of $t_b - t_a$.

When going over to the cumulants $\frac{1}{2}\langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega,c}$ according to (3.507), the $k = n$ -term is eliminated and we obtain

$$\frac{1}{2}\langle n|\mathcal{A}_{\text{int}}^2|n\rangle_{\omega,c} = -\sum_{k \neq n} \frac{V_{nk}V_{kn}}{E_k - E_n} i\hbar(t_b - t_a). \quad (3.517)$$

For the energy shifts up to second order in $V(x)$, we thus arrive at the simple formula

$$\Delta_1 E_n + \Delta_2 E_n = V_{nn} - \sum_{k \neq n} \frac{V_{nk}V_{kn}}{E_k - E_n}. \quad (3.518)$$

The higher expansion coefficients become rapidly complicated. The correction of third order in $V(x)$, for example, is

$$\Delta_3 E_n = \sum_{k \neq n} \sum_{l \neq n} \frac{V_{nk}V_{kl}V_{ln}}{(E_k - E_n)(E_l - E_n)} - V_{nn} \sum_{k \neq n} \frac{V_{nk}V_{kn}}{(E_k - E_n)^2}. \quad (3.519)$$

For comparison, we recall the well-known formula of *Brillouin-Wigner equation*¹⁴

$$\Delta E_n = \bar{R}_{nn}(E_n + \Delta E_n), \quad (3.520)$$

where $\bar{R}_{nn}(E)$ are the diagonal matrix elements $\langle n|\hat{R}(E)|n\rangle$ of the *level shift operator* $\hat{R}(E)$ which solves the integral equation

$$\hat{R}(E) = \hat{V} + \hat{V} \frac{1 - \hat{P}_n}{E - \hat{H}_\omega} \hat{R}(E). \quad (3.521)$$

The operator $\hat{P}_n \equiv |n\rangle\langle n|$ is the projection operator onto the state $|n\rangle$. The factors $1 - \hat{P}_n$ ensure that the sums over the intermediate states exclude the quantum

¹⁴L. Brillouin and E.P. Wigner, J. Phys. Radium **4**, 1 (1933); M.L. Goldberger and K.M. Watson, *Collision Theory*, John Wiley & Sons, New York, 1964, pp. 425–430.

number n of the state under consideration. The integral equation is solved by the series expansion in powers of \hat{V} :

$$\hat{R}(E) = \hat{V} + \hat{V} \frac{1 - \hat{P}_n}{E - \hat{H}_\omega} \hat{V} + \hat{V} \frac{1 - \hat{P}_n}{E - \hat{H}_\omega} \hat{V} \frac{1 - \hat{P}_n}{E - \hat{H}_\omega} \hat{V} + \dots \quad (3.522)$$

Up to the third order in \hat{V} , Eq. (3.520) leads to the *Brillouin-Wigner perturbation expansion*

$$E - E_n = R_{nn}(E) = V_{nn} + \sum_{k \neq n} \frac{V_{nk} V_{kn}}{E - E_k} + \sum_{k \neq n} \sum_{l \neq n} \frac{V_{nk} V_{kl} V_{ln}}{(E - E_k)(E - E_l)} + \dots, \quad (3.523)$$

which is an implicit equation for $\Delta E_n = E - E_n$. The Brillouin-Wigner equation (3.520) may be converted into an explicit equation for the level shift ΔE_n :

$$\begin{aligned} \Delta E_n = & R_{nn}(E_n) + R_{nn}(E_n)R'_{nn}(E_n) + [R_{nn}(E_n)R'_{nn}(E_n)]^2 + \frac{1}{2}R_{nn}^2(E_n)R''_{nn}(E_n) \\ & + [R_{nn}(E_n)R'_{nn}(E_n)]^3 + \frac{3}{2}R_{nn}^2(E_n)R'_{nn}(E_n)R''_{nn}(E_n) + \frac{1}{6}R_{nn}^3(E_n)R'''_{nn}(E_n) + \dots \end{aligned} \quad (3.524)$$

Inserting (3.523) on the right-hand side, we recover the standard *Rayleigh-Schrödinger perturbation expansion* of quantum mechanics, which coincides precisely with the above perturbation expansion of the path integral whose first three terms were given in (3.518) and (3.519). Note that starting from the third order, the explicit solution (3.524) for the level shift introduces more and more extra disconnected terms with respect to the simple systematics in the Brillouin-Wigner expansion (3.523).

For arbitrary potentials, the calculation of the matrix elements V_{nk} can become quite tedious. A simple technique to find them is presented in Appendix 3A.

The calculation of the energy shifts for the particular interaction $V(x) = gx^4/4$ is described in Appendix 3B. Up to order g^3 , the result is

$$\begin{aligned} \Delta E_n = & \frac{\hbar\omega}{2}(2n+1) + \frac{g}{4}3(2n^2+2n+1)a^4 \\ & - \left(\frac{g}{4}\right)^2 2(34n^3+51n^2+59n+21)a^8 \frac{1}{\hbar\omega} \\ & + \left(\frac{g}{4}\right)^3 4 \cdot 3(125n^4+250n^3+472n^2+347n+111)a^{12} \frac{1}{\hbar^2\omega^2}. \end{aligned} \quad (3.525)$$

The perturbation series for this as well as arbitrary polynomial potentials can be carried out to high orders via recursion relations for the expansion coefficients. This is done in Appendix 3C.

3.19 Level-Shifts and Perturbed Wave Functions from Schrödinger Equation

It is instructive to rederive the perturbation expansion from ordinary operator Schrödinger theory. This derivation provides us also with the perturbed eigenstates to any desired order.

The Hamiltonian operator \hat{H} is split into a free and an interacting part

$$\hat{H} = \hat{H}_0 + \hat{V}. \quad (3.526)$$

Let $|n\rangle$ be the eigenstates of \hat{H}_0 and $|\psi^{(n)}\rangle$ those of \hat{H} :

$$\hat{H}_0|n\rangle = E_0^{(n)}|n\rangle, \quad \hat{H}|\psi^{(n)}\rangle = E^{(n)}|\psi^{(n)}\rangle. \quad (3.527)$$

We shall assume that the two sets of states $|n\rangle$ and $|\psi^{(n)}\rangle$ are orthogonal sets, the first with unit norm, the latter normalized by scalar products

$$a_n^{(n)} \equiv \langle n|\psi^{(n)}\rangle = 1. \quad (3.528)$$

Due to the completeness of the states $|n\rangle$, the states $|\psi^{(n)}\rangle$ can be expanded as

$$|\psi^{(n)}\rangle = |n\rangle + \sum_{m \neq n} a_m^{(n)}|m\rangle, \quad (3.529)$$

where

$$a_m^{(n)} \equiv \langle m|\psi^{(n)}\rangle \quad (3.530)$$

are the components of the interacting states in the free basis. Projecting the right-hand Schrödinger equation in (3.527) onto $\langle m|$ and using (3.530), we obtain

$$E_0^{(m)} a_m^{(n)} + \langle m|\hat{V}|\psi^{(n)}\rangle = E^{(n)} a_m^{(n)}. \quad (3.531)$$

Inserting here (3.529), this becomes

$$E_0^{(m)} a_m^{(n)} + \langle m|\hat{V}|n\rangle + \sum_{k \neq n} a_k^{(n)} \langle m|\hat{V}|k\rangle = E^{(n)} a_m^{(n)}, \quad (3.532)$$

and for $m = n$, due to the special normalization (3.528),

$$E_0^{(n)} + \langle n|\hat{V}|n\rangle + \sum_{k \neq n} a_k^{(n)} \langle n|\hat{V}|k\rangle = E^{(n)}. \quad (3.533)$$

Multiplying this equation with $a_m^{(n)}$ and subtracting it from (3.532), we eliminate the unknown exact energy $E^{(n)}$, and obtain a set of coupled algebraic equations for $a_m^{(n)}$:

$$a_m^{(n)} = \frac{1}{E_0^{(n)} - E_0^{(m)}} \left[\langle m - a_m^{(n)}n|\hat{V}|n\rangle + \sum_{k \neq n} a_k^{(n)} \langle m - a_m^{(n)}n|\hat{V}|k\rangle \right], \quad (3.534)$$

where we have introduced the notation $\langle m - a_m^{(n)}n|$ for the combination of states $\langle m| - a_m^{(n)}\langle n|$, for brevity.

This equation can now easily be solved perturbatively order by order in powers of the interaction strength. To count these, we replace \hat{V} by $g\hat{V}$ and expand $a_m^{(n)}$ as well as the energies $E^{(n)}$ in powers of g as:

$$a_m^{(n)}(g) = \sum_{l=1}^{\infty} a_{m,l}^{(n)} (-g)^l \quad (m \neq n), \quad (3.535)$$

and

$$E^{(n)} = E_0^{(n)} - \sum_{l=1}^{\infty} (-g)^l E_l^{(n)}. \quad (3.536)$$

Inserting these expansions into (3.533), and equating the coefficients of g , we immediately find the perturbation expansion of the energy of the n th level

$$E_1^{(n)} = \langle n | \hat{V} | n \rangle, \quad (3.537)$$

$$E_l^{(n)} = \sum_{k \neq n} a_{k,l-1}^{(n)} \langle n | \hat{V} | k \rangle \quad l > 1. \quad (3.538)$$

The expansion coefficients $a_{m,l}^{(n)}$ are now determined by inserting the ansatz (3.535) into (3.534). This yields

$$a_{m,1}^{(n)} = \frac{\langle m | \hat{V} | n \rangle}{E_0^{(m)} - E_0^{(n)}}, \quad (3.539)$$

and for $l > 1$:

$$a_{m,l}^{(n)} = \frac{1}{E_0^{(m)} - E_0^{(n)}} \left[-a_{m,l-1}^{(n)} \langle n | \hat{V} | n \rangle + \sum_{k \neq n} a_{k,l-1}^{(n)} \langle m | \hat{V} | k \rangle - \sum_{l'=1}^{l-2} a_{m,l'}^{(n)} \sum_{k \neq n} a_{k,l-1-l'}^{(n)} \langle n | \hat{V} | k \rangle \right]. \quad (3.540)$$

Using (3.537) and (3.538), this can be simplified to

$$a_{m,l}^{(n)} = \frac{1}{E_0^{(m)} - E_0^{(n)}} \left[\sum_{k \neq n} a_{k,l-1}^{(n)} \langle m | \hat{V} | k \rangle - \sum_{l'=1}^{l-1} a_{m,l'}^{(n)} E_{l-l'}^{(n)} \right]. \quad (3.541)$$

Together with (3.537), (3.538), and (3.539), this is a set of recursion relations for the coefficients $a_{m,l}^{(n)}$ and $E_l^{(n)}$.

The recursion relations allow us to recover the perturbation expansions (3.518) and (3.519) for the energy shift. The second-order result (3.518), for example, follows directly from (3.540) and (3.541), the latter giving

$$E_2^{(n)} = \sum_{k \neq n} a_{k,1}^{(n)} \langle n | \hat{V} | k \rangle = \sum_{k \neq n} \frac{\langle k | \hat{V} | n \rangle \langle n | \hat{V} | k \rangle}{E_0^{(k)} - E_0^{(n)}}. \quad (3.542)$$

If the potential $\hat{V} = V(\hat{x})$ is a polynomial in \hat{x} , its matrix elements $\langle n | \hat{V} | k \rangle$ are nonzero only for n in a finite neighborhood of k , and the recursion relations consist of finite sums which can be solved exactly.

3.20 Calculation of Perturbation Series via Feynman Diagrams

The expectation values in formula (3.487) can be evaluated also in another way which can be applied to all potentials which are simple polynomials of x . Then the partition function can be expanded into a sum of integrals associated with certain *Feynman diagrams*.

The procedure is rooted in the Wick expansion of correlation functions in Section 3.10. To be specific, we assume the anharmonic potential to have the form

$$V(x) = \frac{g}{4} x^4. \quad (3.543)$$

The graphical expansion terms to be found will be typical for all so-called φ^4 -theories of quantum field theory.

To calculate the free energy shift (3.487) to first order in g , we have to evaluate the harmonic expectation of $\mathcal{A}_{\text{int,e}}$. This is written as

$$\langle \mathcal{A}_{\text{int,e}} \rangle_{\omega} = \frac{g}{4} \int_0^{\hbar\beta} d\tau \langle x^4(\tau) \rangle_{\omega}. \quad (3.544)$$

The integrand contains the correlation function

$$\langle x(\tau_1)x(\tau_2)x(\tau_3)x(\tau_4) \rangle_{\omega} = G_{\omega^2}^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4)$$

at identical time arguments. According to the Wick rule (3.305), this can be expanded into the sum of three pair terms

$$G_{\omega^2}^{(2)}(\tau_1, \tau_2)G_{\omega^2}^{(2)}(\tau_3, \tau_4) + G_{\omega^2}^{(2)}(\tau_1, \tau_3)G_{\omega^2}^{(2)}(\tau_2, \tau_4) + G_{\omega^2}^{(2)}(\tau_1, \tau_4)G_{\omega^2}^{(2)}(\tau_2, \tau_3),$$

where $G_{\omega^2}^{(2)}(\tau, \tau')$ are the periodic Euclidean Green functions of the harmonic oscillator [see (3.304) and (3.251)]. The expectation (3.544) is therefore equal to the integral

$$\langle \mathcal{A}_{\text{int,e}} \rangle_{\omega} = 3 \frac{g}{4} \int_0^{\hbar\beta} d\tau G_{\omega^2}^{(2)}(\tau, \tau)^2. \quad (3.545)$$

The right-hand side is pictured by the Feynman diagram

Because of its shape this is called a two-loop diagram. In general, a Feynman diagram consists of lines meeting at points called *vertices*. A line connecting two points represents the Green function $G_{\omega^2}^{(2)}(\tau_1, \tau_2)$. A vertex indicates a factor $g/4\hbar$ and a variable τ to be integrated over the interval $(0, \hbar\beta)$. The present simple diagram has only one point, and the τ -arguments of the Green functions coincide. The number underneath counts how often the integral occurs. It is called the *multiplicity* of the diagram.

To second order in $V(x)$, the harmonic expectation to be evaluated is

$$\langle \mathcal{A}_{\text{int,e}}^2 \rangle_{\omega} = \left(\frac{g}{4}\right)^2 \int_0^{\hbar\beta} d\tau_2 \int_0^{\hbar\beta} d\tau_1 \langle x^4(\tau_2)x^4(\tau_1) \rangle_{\omega}. \quad (3.546)$$

The integral now contains the correlation function $G_{\omega^2}^{(8)}(\tau_1, \dots, \tau_8)$ with eight time arguments. According to the Wick rule, it decomposes into a sum of $7!! = 105$ products of four Green functions $G_{\omega^2}^{(2)}(\tau, \tau')$. Due to the coincidence of the time arguments, there are only three different types of contributions to the integral (3.546):

$$\begin{aligned} \langle \mathcal{A}_{\text{int,e}}^2 \rangle_{\omega} = \left(\frac{g}{4}\right)^2 \int_0^{\hbar\beta} d\tau_2 \int_0^{\hbar\beta} d\tau_1 & \left[72 G_{\omega^2}^{(2)}(\tau_2, \tau_2) G_{\omega^2}^{(2)}(\tau_2, \tau_1)^2 G_{\omega^2}^{(2)}(\tau_1, \tau_1) \right. \\ & \left. + 24 G_{\omega^2}^{(2)}(\tau_2, \tau_1)^4 + 9 G_{\omega^2}^{(2)}(\tau_2, \tau_2)^2 G_{\omega^2}^{(2)}(\tau_1, \tau_1)^2 \right]. \end{aligned} \quad (3.547)$$

The integrals are pictured by the following Feynman diagrams composed of three loops:

They contain two vertices indicating two integration variables τ_1, τ_2 . The first two diagrams with the shape of three bubbles in a chain and of a watermelon, respectively, are *connected* diagrams, the third is *disconnected*. When going over to the cumulant $\langle \mathcal{A}_{\text{int,e}}^2 \rangle_{\omega,c}$, the disconnected diagram is eliminated.

To higher orders, the counting becomes increasingly tedious and it is worth developing computer-algebraic techniques for this purpose. Figure 3.7 shows the diagrams for the free-energy shift up to four loops. The cumulants eliminate precisely all disconnected diagrams. This diagram-rearranging property of the logarithm is very general and happens to every order in g , as can be shown with the help of functional differential equations.

$$\beta F = \beta F_\omega + \underbrace{\text{diagram}}_3 - \frac{1}{2!} \left(\underbrace{\text{diagram}}_{72} + \underbrace{\text{diagram}}_{24} \right) + \frac{1}{3!} \left(\underbrace{\text{diagram}}_{2592} + \underbrace{\text{diagram}}_{1728} + \underbrace{\text{diagram}}_{3456} + \underbrace{\text{diagram}}_{1728} \right) + \dots$$

Figure 3.7 Perturbation expansion of free energy up to order g^3 (four loops).

The lowest-order term βF_ω containing the free energy of the harmonic oscillator [recall Eqs. (3.245) and (2.526)]

$$F_\omega = \frac{1}{\beta} \log \left(2 \sinh \frac{\beta \hbar \omega}{2} \right) \tag{3.548}$$

is often represented by the one-loop diagram

$$\beta F_\omega = -\frac{1}{2} \text{Tr} \log G_{\omega^2}^{(2)} = -\frac{1}{2\hbar\beta} \int_0^{\hbar\beta} d\tau [\log G_{\omega^2}^{(2)}](\tau, \tau) = -\frac{1}{2} \text{diagram} \tag{3.549}$$

With it, the graphical expansion in Fig. 3.7 starts more systematically with one loop rather than two. The systematics is, however, not perfect since the line in the one-loop diagram does not show that integrand contains a logarithm. In addition, the line is not connected to any vertex.

All τ -variables in the diagrams are integrated out. The diagrams have no open lines and are called *vacuum diagrams*.

The calculation of the diagrams in Fig. 3.7 is simplified with the help of a factorization property: If a diagram consists of two subdiagrams touching each other

at a single vertex, its Feynman integral factorizes into those of the subdiagrams. Thanks to this property, we only have to evaluate the following integrals (omitting the factors $g/4\hbar$ for each vertex)

$$\begin{aligned}
 \text{○} &= \int_0^{\hbar\beta} d\tau G_{\omega^2}^{(2)}(\tau, \tau) = \hbar\beta a^2, \\
 \text{⊙} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 G_{\omega^2}^{(2)}(\tau_1, \tau_2)^2 \equiv \hbar\beta \frac{1}{\omega} a_2^4, \\
 \text{⊚} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 d\tau_3 G_{\omega^2}^{(2)}(\tau_1, \tau_2) G_{\omega^2}^{(2)}(\tau_2, \tau_3) G_{\omega^2}^{(2)}(\tau_3, \tau_1) \\
 &\equiv \hbar\beta \left(\frac{1}{\omega}\right)^2 a_3^6, \\
 \text{⊕} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 G_{\omega^2}^{(2)}(\tau_1, \tau_2)^4 \equiv \hbar\beta \frac{1}{\omega} a_2^8, \\
 \text{⊗} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 d\tau_3 G_{\omega^2}^{(2)}(\tau_1, \tau_2) G_{\omega^2}^{(2)}(\tau_2, \tau_3) G_{\omega^2}^{(2)}(\tau_3, \tau_1)^3 \\
 &\equiv \hbar\beta \left(\frac{1}{\omega}\right)^2 a_3^{10}, \\
 \text{⊘} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 d\tau_3 G_{\omega^2}^{(2)}(\tau_1, \tau_2)^2 G_{\omega^2}^{(2)}(\tau_2, \tau_3)^2 G_{\omega^2}^{(2)}(\tau_3, \tau_1)^2 \\
 &\equiv \hbar\beta \left(\frac{1}{\omega}\right)^2 a_3^{12}. \tag{3.550}
 \end{aligned}$$

Note that in each expression, the last τ -integral yields an overall factor $\hbar\beta$, due to the translational invariance along the τ -axis. The others give rise to a factor $1/\omega$, for dimensional reasons. The temperature-dependent quantities a_V^{2L} are labeled by the number of vertices V and lines L of the associated diagrams. Their dimension is length to the n th power [corresponding to the dimension of the n $x(\tau)$ -variables in the diagram]. For more than four loops, there can be more than one diagram for each V and L , such that one needs an additional label in a_V^{2L} to specify the diagram uniquely. Each a_V^{2L} may be written as a product of the basic length scale $(\hbar/M\omega)^L$ multiplied by a function of the dimensionless variable $x \equiv \beta\hbar\omega$:

$$a_V^{2L} = \left(\frac{\hbar}{M\omega}\right)^L \alpha_V^{2L}(x). \tag{3.551}$$

The functions $\alpha_V^{2L}(x)$ are listed in Appendix 3D.

As an example for the application of the factorization property, take the Feynman integral of the second third-order diagram in Fig. 3.7 (called a “daisy” diagram

because of its shape):

$$\begin{aligned}
 \text{Diagram} &= \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 d\tau_3 G_{\omega^2}^{(2)}(\tau_1, \tau_2) G_{\omega^2}^{(2)}(\tau_2, \tau_3) G_{\omega^2}^{(2)}(\tau_3, \tau_1) \\
 &\quad \times G_{\omega^2}^{(2)}(\tau_1, \tau_1) G_{\omega^2}^{(2)}(\tau_2, \tau_2) G_{\omega^2}^{(2)}(\tau_3, \tau_3).
 \end{aligned}$$

It decomposes into a product between the third integral in (3.550) and three powers of the first integral:

$$\text{Diagram} \rightarrow \text{Diagram}_1 \times \text{Diagram}_2^3.$$

Thus we can immediately write

$$\text{Diagram} = \hbar\beta \left(\frac{1}{\omega}\right)^2 a_3^6 (a^2)^3.$$

In terms of a_V^{2L} , the free energy becomes

$$\begin{aligned}
 F &= F_\omega + \frac{g}{4} 3a^4 - \frac{1}{2!\hbar\omega} \left(\frac{g}{4}\right)^2 (72a^2 a_2^4 a^2 + 24a_2^8) \\
 &\quad + \frac{1}{3!\hbar^2\omega^2} \left(\frac{g}{4}\right)^3 [2592a^2 (a_2^4)^2 a^2 + 1728a_3^6 (a^2)^3 + 3456a_3^{10} a^2 + 1728a_3^{12}] + \dots
 \end{aligned} \tag{3.552}$$

In the limit $T \rightarrow 0$, the integrals (3.550) behave like

$$\begin{aligned}
 a_2^4 &\rightarrow a^4, & a_3^6 &\rightarrow \frac{3}{2}a^6, \\
 a_2^8 &\rightarrow \frac{1}{2}a^8, & a_3^{10} &\rightarrow \frac{5}{8}a^{10}, \\
 a_3^{12} &\rightarrow \frac{3}{8}a^{12},
 \end{aligned} \tag{3.553}$$

and the free energy reduces to

$$F = \frac{\hbar\omega}{2} + \frac{g}{4} 3a^4 - \left(\frac{g}{4}\right)^2 42a^8 \frac{1}{\hbar\omega} + \left(\frac{g}{4}\right)^3 4 \cdot 333a^{12} \left(\frac{1}{\hbar\omega}\right)^2 + \dots \tag{3.554}$$

In this limit, it is simpler to calculate the integrals (3.550) directly with the zero-temperature limit of the Green function (3.304), which is $G_{\omega^2}^{(2)}(\tau, \tau') = a^2 e^{-\omega|\tau-\tau'|}$ with $a^2 = \hbar/2\omega M$ [see (3.251)]. The limits of integration must, however, be shifted by half a period to $\int_{-\hbar\beta/2}^{\hbar\beta/2} d\tau$ before going to the limit, so that one evaluates $\int_{-\infty}^{\infty} d\tau$ rather than $\int_0^{\infty} d\tau$ (the latter would give the wrong limit since it misses the left-hand side of the peak at $\tau = 0$). Before integration, the integrals are conveniently split as in Eq. (3D.1).

3.21 Perturbative Definition of Interacting Path Integrals

In Section 2.15 we have seen that it is possible to define a harmonic path integral without time slicing by dimensional regularization. With the techniques developed so far, this definition can trivially be extended to path integrals with interactions, if these can be treated perturbatively. We recall that in Eq. (3.483), the partition function of an interacting system can be expanded in a series of harmonic expectation values of powers of the interaction. The procedure is formulated most conveniently in terms of the generating functional (3.489) using formula (3.490) for the generating functional with interactions and Eq. (3.491) for the associated partition. The harmonic generating functional on the right-hand side of (3.490),

$$Z_\omega[j] = \oint \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) - jx \right] \right\}, \quad (3.555)$$

can be evaluated with analytic regularization as described in Section (2.15) and yields, after a quadratic completion [recall (3.246), (3.247)]:

$$Z_\omega[j] = \frac{1}{2 \sin(\omega\hbar\beta/2)} \exp \left\{ \frac{1}{2M\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^p(\tau - \tau') j(\tau') \right\}, \quad (3.556)$$

where $G_{\omega^2, e}^p(\tau)$ is the periodic Green function (3.251)

$$G_{\omega^2, e}^p(\tau) = \frac{1}{2\omega} \frac{\cosh \omega(\tau - \hbar\beta/2)}{\sinh(\beta\hbar\omega/2)}, \quad \tau \in [0, \hbar\beta]. \quad (3.557)$$

As a consequence, Formula (3.490) for the generating functional of an interacting theory

$$Z[j] = e^{-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau V(\hbar\delta/\delta j(\tau))} Z_\omega[j], \quad (3.558)$$

is completely defined by analytic regularization. By expanding the exponential prefactor as in Eq. (3.493), the full generating functional is obtained from the harmonic one without any further path integration. Only functional differentiations are required to find the generating functional of all interacting correlation functions $Z[j]$ from the harmonic one $Z_\omega[j]$.

This procedure yields the perturbative definition of arbitrary path integrals. It is widely used in the quantum field theory of particle physics¹⁵ and critical phenomena¹⁶ It is also the basis for an important extension of the theory of distributions to be discussed in detail in Sections 10.6–10.11.

It must be realized, however, that the perturbative definition is not a complete definition. Important contributions to the path integral may be missing: all those

¹⁵C. Itzykson and J.-B. Zuber, *Quantum Field Theory*, McGraw-Hill (1985).

¹⁶H. Kleinert and V. Schulte-Frohlinde, *Critical Properties of ϕ^4 -Theories*, World Scientific, Singapore 2001, pp. 1–487 (www.physik.fu-berlin.de/~kleinert/re.html#b8).

which are not expandable in powers of the interaction strength g . Such contributions are essential in understanding many physical phenomena, for example, tunneling, to be discussed in Chapter 17. Interestingly, however, information on such phenomena can, with appropriate resummation techniques to be developed in Chapter 5, also be extracted from the large-order behavior of the perturbation expansions, as will be shown in Subsection 17.10.4.

3.22 Generating Functional of Connected Correlation Functions

In Section 3.10 we have seen that the correlation functions obtained from the functional derivatives of $Z[j]$ via relation (3.298) contain many disconnected parts. The physically relevant free energy $F[j] = -k_B T \log Z[j]$, on the other hand, contains only in the connected parts of $Z[j]$. In fact, from statistical mechanics we know that meaningful description of a very large thermodynamic system can only be given in terms of the free energy which is directly proportional to the total volume V . The partition function $Z = e^{-F/k_B T}$ has no meaningful infinite-volume limit, also called the *thermodynamic limit*, since it contains a power series in V . Only the free energy density $f \equiv F/V$ has an infinite-volume limit. The expansion of $Z[j]$ diverges therefore for $V \rightarrow \infty$. This is why in thermodynamics we always go over to the free energy density by taking the logarithm of the partition function. This is calculated entirely from the connected diagrams.

Due to this thermodynamic experience we expect the logarithm of $Z[j]$ to provide us with a generating functional for all connected correlation functions. To avoid factors $k_B T$ we define this functional as

$$W[j] = \log Z[j], \quad (3.559)$$

and shall now prove that the functional derivatives of $W[j]$ produce precisely the connected parts of the Feynman diagrams for each correlation function.

Consider the connected correlation functions $G_c^{(n)}(\tau_1, \dots, \tau_n)$ defined by the functional derivatives

$$G_c^{(n)}(\tau_1, \dots, \tau_n) = \frac{\delta}{\delta j(\tau_1)} \cdots \frac{\delta}{\delta j(\tau_n)} W[j]. \quad (3.560)$$

Ultimately, we shall be interested only in these functions with zero external current, where they reduce to the physically relevant connected correlation functions. For the general development in this section, however, we shall consider them as functionals of $j(\tau)$, and set $j = 0$ only at the end.

Of course, given all connected correlation functions $G_c^{(n)}(\tau_1, \dots, \tau_n)$, the full correlation functions $G^{(n)}(\tau_1, \dots, \tau_n)$ in Eq. (3.298) can be recovered via simple composition laws from the connected ones. In order to see this clearly, we shall derive the general relationship between the two types of correlation functions in Section 3.22.2. First, we shall prove the connectedness property of the derivatives (3.560).

3.22.1 Connectedness Structure of Correlation Functions

We first prove that the generating functional $W[j]$ collects *only* connected diagrams in its Taylor coefficients $\delta^n W / \delta j(\tau_1) \dots \delta j(\tau_n)$. Later, after Eq. (3.588), we shall see that these functional derivatives comprise *all* connected diagrams in $G^{(n)}(\tau_1, \dots, \tau_n)$.

Let us write the path integral for the generating functional $Z[j]$ as follows (here we use natural units with $\hbar = 1$):

$$Z[j] = \int \mathcal{D}x e^{-\mathcal{A}_e[x,j]/\hbar}, \quad (3.561)$$

with the action

$$\mathcal{A}_e[x, j] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) + V(x) - j(\tau)x(\tau) \right]. \quad (3.562)$$

In the following structural considerations we shall use natural physical units in which $\hbar = 1$, for simplicity of the formulas. By analogy with the integral identity

$$\int dx \frac{d}{dx} e^{-F(x)} = 0,$$

which holds by partial integration for any function $F(x)$ which goes to infinity for $x \rightarrow \pm\infty$, the functional integral satisfies the identity

$$\int \mathcal{D}x \frac{\delta}{\delta x(\tau)} e^{-\mathcal{A}_e[x,j]} = 0, \quad (3.563)$$

since the action $\mathcal{A}_e[x, j]$ goes to infinity for $x \rightarrow \pm\infty$. Performing the functional derivative, we obtain

$$\int \mathcal{D}x \frac{\delta \mathcal{A}_e[x, j]}{\delta x(\tau)} e^{-\mathcal{A}_e[x,j]} = 0. \quad (3.564)$$

To be specific, let us consider the anharmonic oscillator with potential $V(x) = \lambda x^4/4!$. We have chosen a coupling constant $\lambda/4!$ instead of the previous g in (3.543) since this will lead to more systematic numeric factors. The functional derivative of the action yields the classical equation of motion

$$\frac{\delta \mathcal{A}_e[x, j]}{\delta x(\tau)} = M(-\ddot{x} + \omega^2 x) + \frac{\lambda}{3!} x^3 - j = 0, \quad (3.565)$$

which we shall write as

$$\frac{\delta \mathcal{A}_e[x, j]}{\delta x(\tau)} = G_0^{-1} x + \frac{\lambda}{3!} x^3 - j = 0, \quad (3.566)$$

where we have set $G_0(\tau, \tau') \equiv G^{(2)}$ to get free space for upper indices. With this notation, Eq. (3.564) becomes

$$\int \mathcal{D}x \left\{ G_0^{-1} x(\tau) + \frac{\lambda}{3!} x^3(\tau) - j(\tau) \right\} e^{-\mathcal{A}_e[x,j]} = 0. \quad (3.567)$$

We now express the paths $x(\tau)$ as functional derivatives with respect to the source current $j(\tau)$, such that we can pull the curly brackets in front of the integral. This leads to the functional differential equation for the generating functional $Z[j]$:

$$\left\{ G_0^{-1} \frac{\delta}{\delta j(\tau)} + \frac{\lambda}{3!} \left[\frac{\delta}{\delta j(\tau)} \right]^3 - j(\tau) \right\} Z[j] = 0. \quad (3.568)$$

With the short-hand notation

$$Z_{j(\tau_1)j(\tau_2)\dots j(\tau_n)}[j] \equiv \frac{\delta}{\delta j(\tau_1)} \frac{\delta}{\delta j(\tau_2)} \cdots \frac{\delta}{\delta j(\tau_n)} Z[j], \quad (3.569)$$

where the arguments of the currents will eventually be suppressed, this can be written as

$$G_0^{-1} Z_{j(\tau)} + \frac{\lambda}{3!} Z_{j(\tau)j(\tau)j(\tau)} - j(\tau) = 0. \quad (3.570)$$

Inserting here (3.559), we obtain a functional differential equation for $W[j]$:

$$G_0^{-1} W_j + \frac{\lambda}{3!} (W_{jjj} + 3W_{jj}W_j + W_j^3) - j = 0. \quad (3.571)$$

We have employed the same short-hand notation for the functional derivatives of $W[j]$ as in (3.569) for $Z[j]$,

$$W_{j(\tau_1)j(\tau_2)\dots j(\tau_n)}[j] \equiv \frac{\delta}{\delta j(\tau_1)} \frac{\delta}{\delta j(\tau_2)} \cdots \frac{\delta}{\delta j(\tau_n)} W[j], \quad (3.572)$$

suppressing the arguments τ_1, \dots, τ_n of the currents, for brevity. Multiplying (3.571) functionally by G_0 gives

$$W_j = -\frac{\lambda}{3!} G_0 (W_{jjj} + 3W_{jj}W_j + W_j^3) + G_0 j. \quad (3.573)$$

We have omitted the integral over the intermediate τ 's, for brevity. More specifically, we have written $G_0 j$ for $\int d\tau' G_0(\tau, \tau') j(\tau')$. Similar expressions abbreviate all functional products. This corresponds to a functional version of *Einstein's summation convention*.

Equation (3.573) may now be expressed in terms of the one-point correlation function

$$G_c^{(1)} = W_j, \quad (3.574)$$

defined in (3.560), as

$$G_c^{(1)} = -\frac{\lambda}{3!} G_0 \left\{ G_{cjj}^{(1)} + 3G_{cj}^{(1)} G_c^{(1)} + [G_c^{(1)}]^3 \right\} + G_0 j. \quad (3.575)$$

The solution to this equation is conveniently found by a diagrammatic procedure displayed in Fig. 3.8. To lowest, zeroth, order in λ we have

$$G_c^{(1)} = G_0 j. \tag{3.576}$$

From this we find by functional integration the zeroth order generating functional $W_0[j]$

$$W_0[j] = \int \mathcal{D}j G_c^{(1)} = \frac{1}{2} j G_0 j, \tag{3.577}$$

up to a j -independent constant. Subscripts of $W[j]$ indicate the order in the interaction strength λ .

Reinserting (3.576) on the right-hand side of (3.575) gives the first-order expression

$$G_c^{(1)} = -G_0 \frac{\lambda}{3!} [3G_0 G_0 j + (G_0 j)^3] + G_0 j, \tag{3.578}$$

represented diagrammatically in the second line of Fig. 3.8. Equation (3.578) can be integrated functionally in j to obtain $W[j]$ up to first order in λ . Diagrammatically, this process amounts to multiplying each open lines in a diagram by a current j , and dividing the arising j^n s by n . Thus we arrive at

$$W_0[j] + W_1[j] = \frac{1}{2} j G_0 j - \frac{\lambda}{4} G_0 (G_0 j)^2 - \frac{\lambda}{24} (G_0 j)^4, \tag{3.579}$$

Figure 3.8 Diagrammatic solution of recursion relation (3.573) for the generating functional $W[j]$ of all connected correlation functions. First line represents Eq. (3.575), second (3.578), third (3.579). The remaining lines define the diagrammatic symbols.

as illustrated in the third line of Fig. 3.8. This procedure can be continued to any order in λ .

The same procedure allows us to prove that the generating functional $W[j]$ collects *only* connected diagrams in its Taylor coefficients $\delta^n W / \delta j(x_1) \dots \delta j(x_n)$. For the lowest two orders we can verify the connectedness by inspecting the third line in Fig. 3.8. The diagrammatic form of the recursion relation shows that this topological property remains true for all orders in λ , by induction. Indeed, if we suppose it to be true for some n , then all $G_c^{(1)}$ inserted on the right-hand side are connected, and so are the diagrams constructed from these when forming $G_c^{(1)}$ to the next, $(n+1)$ st, order.

Note that this calculation is unable to recover the value of $W[j]$ at $j = 0$ which is an unknown integration constant of the functional differential equation. For the purpose of generating correlation functions, this constant is irrelevant. We have seen in Fig. 3.7 that $W[0]$, which is equal to $-F/k_B T$, consists of the sum of all connected vacuum diagrams contained in $Z[0]$.

3.22.2 Correlation Functions versus Connected Correlation Functions

Using the logarithmic relation (3.559) between $W[j]$ and $Z[j]$ we can now derive general relations between the n -point functions and their connected parts. For the one-point function we find

$$G^{(1)}(\tau) = Z^{-1}[j] \frac{\delta}{\delta j(\tau)} Z[j] = \frac{\delta}{\delta j(\tau)} W[j] = G_c^{(1)}(\tau). \quad (3.580)$$

This equation implies that the one-point function representing the ground state expectation value of the path $x(\tau)$ is always connected:

$$\langle x(\tau) \rangle \equiv G^{(1)}(\tau) = G_c^{(1)}(\tau) = X. \quad (3.581)$$

Consider now the two-point function, which decomposes as follows:

$$\begin{aligned} G^{(2)}(\tau_1, \tau_2) &= Z^{-1}[j] \frac{\delta}{\delta j(\tau_1)} \frac{\delta}{\delta j(\tau_2)} Z[j] \\ &= Z^{-1}[j] \frac{\delta}{\delta j(\tau_1)} \left\{ \left(\frac{\delta}{\delta j(\tau_2)} W[j] \right) Z[j] \right\} \\ &= Z^{-1}[j] \left\{ W_{j(\tau_1)j(\tau_2)} + W_{j(\tau_1)} W_{j(\tau_2)} \right\} Z[j] \\ &= G_c^{(2)}(\tau_1, \tau_2) + G_c^{(1)}(\tau_1) G_c^{(1)}(\tau_2). \end{aligned} \quad (3.582)$$

In addition to the connected diagrams with two ends there are two connected diagrams ending in a single line. These are absent in a x^4 -theory at $j = 0$ because of the symmetry of the potential, which makes all odd correlation functions vanish. In that case, the two-point function is automatically connected.

For the three-point function we find

$$\begin{aligned}
G^{(3)}(\tau_1, \tau_2, \tau_3) &= Z^{-1}[j] \frac{\delta}{\delta j(\tau_1)} \frac{\delta}{\delta j(\tau_2)} \frac{\delta}{\delta j(\tau_3)} Z[j] \\
&= Z^{-1}[j] \frac{\delta}{\delta j(\tau_1)} \frac{\delta}{\delta j(\tau_2)} \left\{ \left[\frac{\delta}{\delta j(\tau_3)} W[j] \right] Z[j] \right\} \\
&= Z^{-1}[j] \frac{\delta}{\delta j(\tau_1)} \left\{ \left[W_{j(\tau_3)j(\tau_2)} + W_{j(\tau_2)} W_{j(\tau_3)} \right] Z[j] \right\} \\
&= Z^{-1}[j] \left\{ W_{j(\tau_1)j(\tau_2)j(\tau_3)} + \left(W_{j(\tau_1)} W_{j(\tau_2)j(\tau_3)} + W_{j(\tau_2)} W_{j(\tau_1)j(\tau_3)} \right. \right. \\
&\quad \left. \left. + W_{j(\tau_3)} W_{j(\tau_1)j(\tau_2)} \right) + W_{j(\tau_1)} W_{j(\tau_2)} W_{j(\tau_3)} \right\} Z[j] \\
&= G_c^{(3)}(\tau_1, \tau_2, \tau_3) + \left[G_c^{(1)}(\tau_1) G_c^{(2)}(\tau_2, \tau_3) + 2 \text{ perm} \right] + G_c^{(1)}(\tau_1) G_c^{(1)}(\tau_2) G_c^{(1)}(\tau_3),
\end{aligned} \tag{3.583}$$

and for the four-point function

$$\begin{aligned}
G^{(4)}(\tau_1, \dots, \tau_4) &= G_c^{(4)}(\tau_1, \dots, \tau_4) + \left[G_c^{(3)}(\tau_1, \tau_2, \tau_3) G_c^{(1)}(\tau_4) + 3 \text{ perm} \right] \\
&\quad + \left[G_c^{(2)}(\tau_1, \tau_2) G_c^{(2)}(\tau_3, \tau_4) + 2 \text{ perm} \right] \\
&\quad + \left[G_c^{(2)}(\tau_1, \tau_2) G_c^{(1)}(\tau_3) G_c^{(1)}(\tau_4) + 5 \text{ perm} \right] \\
&\quad + G_c^{(1)}(\tau_1) \cdots G_c^{(1)}(\tau_4).
\end{aligned} \tag{3.584}$$

In the pure x^4 -theory there are no odd correlation functions, because of the symmetry of the potential.

For the general correlation function $G^{(n)}$, the total number of terms is most easily retrieved by dropping all indices and differentiating with respect to j (the arguments τ_1, \dots, τ_n of the currents are again suppressed):

$$\begin{aligned}
G^{(1)} &= e^{-W} \left(e^W \right)_j = W_j = G_c^{(1)} \\
G^{(2)} &= e^{-W} \left(e^W \right)_{jj} = W_{jj} + W_j^2 = G_c^{(2)} + G_c^{(1)2} \\
G^{(3)} &= e^{-W} \left(e^W \right)_{jjj} = W_{jjj} + 3W_{jj}W_j + W_j^3 = G_c^{(3)} + 3G_c^{(2)}G_c^{(1)} + G_c^{(1)3} \\
G^{(4)} &= e^{-W} \left(e^W \right)_{jjjj} = W_{jjjj} + 4W_{jjj}W_j + 3W_{jj}^2 + 6W_{jj}W_j^2 + W_j^4 \\
&= G_c^{(4)} + 4G_c^{(3)}G_c^{(1)} + 3G_c^{(2)2} + 6G_c^{(2)}G_c^{(1)2} + G_c^{(1)4}.
\end{aligned} \tag{3.585}$$

All equations follow from the recursion relation

$$G^{(n)} = G_j^{(n-1)} + G^{(n-1)}G_c^{(1)}, \quad n \geq 2, \tag{3.586}$$

if one uses $G_j^{(n-1)} = G_c^{(n)}$ and the initial relation $G^{(1)} = G_c^{(1)}$. By comparing the first four relations with the explicit expressions (3.582)–(3.584) we see that the numerical factors on the right-hand side of (3.585) refer to the permutations of the arguments $\tau_1, \tau_2, \tau_3, \dots$ of otherwise equal expressions. Since there is no problem in

reconstructing the explicit permutations we shall henceforth write all composition laws in the short-hand notation (3.585).

The formula (3.585) and its generalization is often referred to as *cluster decomposition*, or also as the *cumulant expansion*, of the correlation functions.

We can now prove that the connected correlation functions collect precisely all connected diagrams in the n -point functions. For this we observe that the decomposition rules can be inverted by repeatedly differentiating both sides of the equation $W[j] = \log Z[j]$ functionally with respect to the current j :

$$\begin{aligned} G_c^{(1)} &= G^{(1)} \\ G_c^{(2)} &= G^{(2)} - G^{(1)}G^{(1)} \\ G_c^{(3)} &= G^{(3)} - 3G^{(2)}G^{(1)} + 2G^{(1)3} \\ G_c^{(4)} &= G^{(4)} - 4G^{(3)}G^{(1)} + 12G^{(2)}G^{(1)2} - 3G^{(2)2} - 6G^{(1)4}. \end{aligned} \quad (3.587)$$

Each equation follows from the previous one by one more derivative with respect to j , and by replacing the derivatives on the right-hand side according to the rule

$$G_j^{(n)} = G^{(n+1)} - G^{(n)}G^{(1)}. \quad (3.588)$$

Again the numerical factors imply different permutations of the arguments and the subscript j denotes functional differentiations with respect to j .

Note that Eqs. (3.587) for the connected correlation functions are valid for symmetric as well as asymmetric potentials $V(x)$. For symmetric potentials, the equations simplify, since all terms involving $G^{(1)} = X = \langle x \rangle$ vanish.

It is obvious that any connected diagram contained in $G^{(n)}$ must also be contained in $G_c^{(n)}$, since all the terms added or subtracted in (3.587) are products of $G_j^{(n)}$ s, and thus necessarily disconnected. Together with the proof in Section 3.22.1 that the correlation functions $G_c^{(n)}$ contain *only* the connected parts of $G^{(n)}$, we can now be sure that $G_c^{(n)}$ contains precisely the connected parts of $G^{(n)}$.

3.22.3 Functional Generation of Vacuum Diagrams

The functional differential equation (3.573) for $W[j]$ contains all information on the connected correlation functions of the system. However, it does not tell us anything about the vacuum diagrams of the theory. These are contained in $W[0]$, which remains an undetermined constant of functional integration of these equations.

In order to gain information on the vacuum diagrams, we consider a modification of the generating functional (3.561), in which we set the external source j equal to zero, but generalize the source $j(\tau)$ in (3.561) coupled linearly to $x(\tau)$ to a bilocal form $K(\tau, \tau')$ coupled linearly to $x(\tau)x(\tau')$:

$$Z[K] = \int \mathcal{D}x(\tau) e^{-\mathcal{A}_e[x, K]}, \quad (3.589)$$

where $\mathcal{A}_e[x, K]$ is the Euclidean action

$$\mathcal{A}_e[x, K] \equiv \mathcal{A}_0[x] + \mathcal{A}^{\text{int}}[x] + \frac{1}{2} \int d\tau \int d\tau' x(\tau) K(\tau, \tau') x(\tau'). \quad (3.590)$$

When forming the functional derivative with respect to $K(\tau, \tau')$ we obtain the correlation function in the presence of $K(\tau, \tau')$:

$$G^{(2)}(\tau, \tau') = -2Z^{-1}[K] \frac{\delta Z}{\delta K(\tau, \tau')}. \quad (3.591)$$

At the end we shall set $K(\tau, \tau') = 0$, just as previously the source j . When differentiating $Z[K]$ twice, we obtain the four-point function

$$G^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4) = 4Z^{-1}[K] \frac{\delta^2 Z}{\delta K(\tau_1, \tau_2) \delta K(\tau_3, \tau_4)}. \quad (3.592)$$

As before, we introduce the functional $W[K] \equiv \log Z[K]$. Inserting this into (3.591) and (3.592), we find

$$G^{(2)}(\tau, \tau') = 2 \frac{\delta W}{\delta K(\tau, \tau')}, \quad (3.593)$$

$$G^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4) = 4 \left[\frac{\delta^2 W}{\delta K(\tau_1, \tau_2) \delta K(\tau_3, \tau_4)} + \frac{\delta W}{\delta K(\tau_1, \tau_2)} \frac{\delta W}{\delta K(\tau_3, \tau_4)} \right]. \quad (3.594)$$

With the same short notation as before, we shall use again a subscript K to denote functional differentiation with respect to K , and write

$$G^{(2)} = 2W_K, \quad G^{(4)} = 4[W_{KK} + W_K W_K] = 4W_{KK} + G^{(2)} G^{(2)}. \quad (3.595)$$

From Eq. (3.585) we know that in the absence of a source j and for a symmetric potential, $G^{(4)}$ has the connectedness structure

$$G^{(4)} = G_c^{(4)} + 3G_c^{(2)} G_c^{(2)}. \quad (3.596)$$

This shows that in contrast to W_{jjjj} , the derivative W_{KK} does not directly yield a connected four-point function, but two disconnected parts:

$$4W_{KK} = G_c^{(4)} + 2G_c^{(2)} G_c^{(2)}, \quad (3.597)$$

the two-point functions being automatically connected for a symmetric potential. More explicitly, (3.597) reads

$$\begin{aligned} & \frac{4\delta^2 W}{\delta K(\tau_1, \tau_2) \delta K(\tau_3, \tau_4)} \\ &= G_c^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4) + G_c^{(2)}(\tau_1, \tau_3) G_c^{(2)}(\tau_2, \tau_4) + G_c^{(2)}(\tau_1, \tau_4) G_c^{(2)}(\tau_2, \tau_3). \end{aligned} \quad (3.598)$$

Let us derive functional differential equations for $Z[K]$ and $W[K]$. By analogy with (3.563) we start out with the trivial functional differential equation

$$\int \mathcal{D}x \, x(\tau) \frac{\delta}{\delta x(\tau')} e^{-\mathcal{A}_e[x, K]} = -\delta(\tau - \tau') Z[K], \quad (3.599)$$

which is immediately verified by a functional integration by parts. Performing the functional derivative yields

$$\int \mathcal{D}x x(\tau) \frac{\delta \mathcal{A}_e[x, K]}{\delta x(\tau')} e^{-\mathcal{A}_e[x, K]} = \delta(\tau - \tau') Z[K], \tag{3.600}$$

or

$$\int \mathcal{D}x \int d\tau \int d\tau' \left\{ x(\tau) G_0^{-1}(\tau, \tau') x(\tau') + \frac{\lambda}{3!} x(\tau) x^3(\tau') \right\} e^{-\mathcal{A}_e[x, K]} = \delta(\tau - \tau') Z[K]. \tag{3.601}$$

For brevity, we have absorbed the source in the free-field correlation function G_0 :

$$G_0 \rightarrow [G_0^{-1} - K]^{-1}. \tag{3.602}$$

The left-hand side of (3.601) can obviously be expressed in terms of functional derivatives of $Z[K]$, and we obtain the functional differential equation whose short form reads

$$G_0^{-1} Z_K + \frac{\lambda}{3} Z_{KKK} = \frac{1}{2} Z. \tag{3.603}$$

Inserting $Z[K] = e^{W[K]}$, this becomes

$$G_0^{-1} W_K + \frac{\lambda}{3} (W_{KKK} + W_K W_K) = \frac{1}{2}. \tag{3.604}$$

It is useful to reconsider the functional $W[K]$ as a functional $W[G_0]$. Then $\delta G_0 / \delta K = G_0^2$, and the derivatives of $W[K]$ become

$$W_K = G_0^2 W_{G_0}, \quad W_{KKK} = 2G_0^3 W_{G_0} + G_0^4 W_{G_0 G_0}, \tag{3.605}$$

and (3.604) takes the form

$$G_0 W_{G_0} + \frac{\lambda}{3} (G_0^4 W_{G_0 G_0} + 2G_0^3 W_{G_0} + G_0^4 W_{G_0} W_{G_0}) = \frac{1}{2}. \tag{3.606}$$

This equation is represented diagrammatically in Fig. 3.9. The zeroth-order solution

$$\begin{aligned} \text{Diagram} &= 8 \left[\text{Diagram 1} + 2 \text{Diagram 2} + \text{Diagram 3} \right] + \frac{1}{2} \\ G_0 W_{G_0} &= 8 \frac{-1}{4!} \left[\lambda G_0^4 W_{G_0 G_0} + 2G_0 \lambda G_0^2 W_{G_0} + W_{G_0} G_0^2 \lambda G_0^2 W_{G_0} \right] + \frac{1}{2} \end{aligned}$$

Figure 3.9 Diagrammatic representation of functional differential equation (3.606). For the purpose of finding the multiplicities of the diagrams, it is convenient to represent here by a vertex the coupling strength $-\lambda/4!$ rather than $g/4$ in Section 3.20.

to this equation is obtained by setting $\lambda = 0$:

$$W^{(0)}[G_0] = \frac{1}{2} \text{Tr} \log(G_0). \quad (3.607)$$

Explicitly, the right-hand side is equal to the one-loop contribution to the free energy in Eq. (3.549), apart from a factor $-\beta$.

The corrections are found by iteration. For systematic treatment, we write $W[G_0]$ as a sum of a free and an interacting part,

$$W[G_0] = W^{(0)}[G_0] + W^{\text{int}}[G_0], \quad (3.608)$$

insert this into Eq. (3.606), and find the differential equation for the interacting part:

$$G_0 W_{G_0}^{\text{int}} + \frac{\lambda}{3} (G_0^4 W_{G_0 G_0}^{\text{int}} + 3G_0^3 W_{G_0}^{\text{int}} + G_0^4 W_{G_0}^{\text{int}} W_{G_0}^{\text{int}}) = 6 \frac{-\lambda}{4!} G_0^2. \quad (3.609)$$

This equation is solved iteratively. Setting $W^{\text{int}}[G_0] = 0$ in all terms proportional to λ , we obtain the first-order contribution to $W^{\text{int}}[G_0]$:

$$W^{\text{int}}[G_0] = 3 \frac{-\lambda}{4!} G_0^2. \quad (3.610)$$

This is precisely the contribution (3.545) of the two-loop Feynman diagram (apart from the different normalization of g).

In order to see how the iteration of Eq. (3.609) may be solved systematically, let us ignore for the moment the functional nature of Eq. (3.609), and treat G_0 as an ordinary real variable rather than a functional matrix. We expand $W[G_0]$ in a Taylor series:

$$W^{\text{int}}[G_0] = \sum_{p=1}^{\infty} \frac{1}{p!} W_p \left(\frac{-\lambda}{4!} \right)^p (G_0)^{2p}, \quad (3.611)$$

and find for the expansion coefficients the recursion relation

$$W_{p+1} = 4 \left\{ [2p(2p-1) + 3(2p)] W_p + \sum_{q=1}^{p-1} \binom{p}{q} 2q W_q \times 2(p-q) W_{p-q} \right\}. \quad (3.612)$$

Solving this with the initial number $W_1 = 3$, we obtain the multiplicities of the connected vacuum diagrams of p th order:

$$3, 96, 9504, 1880064, 616108032, 301093355520, 205062331760640, \\ 185587468924354560, 215430701800551874560, 312052349085504377978880. \quad (3.613)$$

To check these numbers, we go over to $Z[G] = e^{W[G_0]}$, and find the expansion:

$$\begin{aligned} Z[G_0] &= \exp \left[\frac{1}{2} \text{Tr} \log G_0 + \sum_{p=1}^{\infty} \frac{1}{p!} W_p \left(\frac{-\lambda}{4!} \right)^p (G_0)^{2p} \right] \\ &= \text{Det}^{1/2}[G_0] \left[1 + \sum_{p=1}^{\infty} \frac{1}{p!} z_p \left(\frac{-\lambda}{4!} \right)^p (G_0)^{2p} \right]. \end{aligned} \quad (3.614)$$

The expansion coefficients z_p count the total number of vacuum diagrams of order p . The exponentiation (3.614) yields $z_p = (4p - 1)!!$, which is the correct number of Wick contractions of p interactions x^4 .

In fact, by comparing coefficients in the two expansions in (3.614), we may derive another recursion relation for W_p :

$$W_p + 3 \binom{p-1}{1} W_{p-1} + 7 \cdot 5 \cdot 3 \binom{p-1}{2} + \dots + (4p - 5)!! \binom{p-1}{p-1} = (4p - 1)!! \tag{3.615}$$

which is fulfilled by the solutions of (3.612).

In order to find the associated Feynman diagrams, we must perform the differentiations in Eq. (3.609) functionally. The numbers W_p become then a sum of diagrams, for which the recursion relation (3.612) reads

$$W_{p+1} = 4 \left[G_0^4 \frac{d^2}{d\cap^2} W_p + 3 \cdot G_0^3 \frac{d}{d\cap} W_p + \sum_{q=1}^{p-1} \binom{p}{q} \left(\frac{d}{d\cap} W_q \right) G_0^2 \cdot G_0^2 \left(\frac{d}{d\cap} W_{p-q} \right) \right], \tag{3.616}$$

where the differentiation $d/d\cap$ removes one line connecting two vertices in all possible ways. This equation is solved diagrammatically, as shown in Fig. 3.10.

$$\begin{aligned} \textcircled{p+1} &= 4 \left[\textcircled{p} \frac{d^2}{d\cap^2} \textcircled{p} + 3 \textcircled{p} \frac{d}{d\cap} \textcircled{p} + \sum_{q=1}^{p-1} \binom{p}{q} \left(\frac{d}{d\cap} \textcircled{p} \right) \textcircled{p-q} \right] \\ W_{p+1} &= 4 \left[G_0^4 \frac{d^2}{d\cap^2} W_p + 3 \cdot G_0^3 \frac{d}{d\cap} W_p + \sum_{q=1}^{p-1} \binom{p}{q} \left(\frac{d}{d\cap} W_q \right) G_0^2 \cdot G_0^2 \left(\frac{d}{d\cap} W_{p-q} \right) \right] \end{aligned}$$

Figure 3.10 Diagrammatic representation of recursion relation (3.612). A vertex represents the coupling strength $-\lambda$.

Starting the iteration with $W_1 = 3 \textcircled{1}$, we have $dW_p/d\cap = 6 \textcircled{2}$ and $d^2W_p/d\cap^2 = 6 \textcircled{3}$. Proceeding to order five loops and going back to the usual vertex notation $-\lambda$, we find the vacuum diagrams with their weight factors as shown in Fig. 3.11. For more than five loops, the reader is referred to the paper quoted in Notes and References, and to the internet address from which **Mathematica** programs can be downloaded which solve the recursion relations and plot all diagrams of $W[0]$ and the resulting two- and four-point functions.

3.22.4 Correlation Functions from Vacuum Diagrams

The vacuum diagrams contain information on all correlation functions of the theory. One may rightly say that the vacuum is the world. The two- and four-point functions are given by the functional derivatives (3.595) of the vacuum functional $W[K]$. Diagrammatically, a derivative with respect to K corresponds to cutting one line of a vacuum diagram in all possible ways. Thus, all diagrams of the two-point function

	diagrams and multiplicities
g^1	$3 \text{ } \circ \circ$
g^2	$\frac{1}{2!} \left(24 \text{ } \textcircled{\ominus} + 72 \text{ } \circ \circ \circ \right)$
g^3	$\frac{1}{3!} \left(1728 \text{ } \textcircled{\nabla} + 3456 \text{ } \textcircled{\ominus} + 2592 \text{ } \circ \circ \circ \circ + 1728 \text{ } \textcircled{\circ} \right)$
g^4	$\frac{1}{4!} \left(62208 \text{ } \textcircled{\square} + 66296 \text{ } \textcircled{\circ} + 248832 \text{ } \textcircled{\circ \circ} + 497664 \text{ } \textcircled{\nabla} + 165888 \text{ } \textcircled{\circ \circ} + 248832 \text{ } \textcircled{\circ \circ} + 165888 \text{ } \textcircled{\circ \circ} + 124416 \text{ } \circ \circ \circ \circ + 248832 \text{ } \circ \circ \textcircled{\circ} + 62208 \text{ } \textcircled{\circ \circ} \right)$

Figure 3.11 Vacuum diagrams up to five loops and their multiplicities. The total numbers to orders g^n are 3, 96, 9504, 1880064, respectively. In contrast to Fig. 3.10, and to the previous diagrammatic notation in Fig. 3.7, a vertex stands here for $-\lambda/4!$ for brevity. For more than five loops see the tables on the internet (<http://users.physik.fu-berlin/~kleinert/b3/programs>).

$G^{(2)}$ can be derived from such cuts, multiplied by a factor 2. As an example, consider the first-order vacuum diagram of $W[K]$ in Fig. 3.11. Cutting one line, which is possible in two ways, and recalling that in Fig. 3.11 a vertex stands for $-\lambda/4!$ rather than $-\lambda$, as in the other diagrams, we find

$$W_1[0] = \frac{1}{8} \text{ } \circ \circ \longrightarrow G_1^{(2)}(\tau_1, \tau_2) = 2 \times \frac{1}{8} 2 \text{ } \textcircled{\circ} . \tag{3.617}$$

The second equation in (3.595) tells us that all connected contributions to the four-point function $G^{(4)}$ may be obtained by cutting two lines in all combinations, and multiplying the result by a factor 4. As an example, take the second-order vacuum diagrams of $W[0]$ with the proper translation of vertices by a factor $4!$, which are

$$W_2[0] = \frac{1}{16} \text{ } \circ \circ \circ + \frac{1}{48} \text{ } \textcircled{\ominus} . \tag{3.618}$$

Cutting two lines in all possible ways yields the following contributions to the connected diagrams of the two-point function:

$$G^{(4)} = 4 \times \left(2 \cdot 1 \cdot \frac{1}{16} + 4 \cdot 3 \cdot \frac{1}{48} \right) \text{ } \textcircled{\circ} . \tag{3.619}$$

It is also possible to find all diagrams of the four-point function from the vacuum diagrams by forming a derivative of $W[0]$ with respect to the coupling constant $-\lambda$, and multiplying the result by a factor $4!$. This follows directly from the fact that this differentiation applied to $Z[0]$ yields the correlation function $\int d\tau \langle x^4 \rangle$. As an example, take the first diagram of order g^3 in Table 3.11 (with the same vertex convention as in Fig. 3.11):

$$W_2[0] = \frac{1}{48} \text{ (triangle with three external lines) } . \quad (3.620)$$

Removing one vertex in the three possible ways and multiplying by a factor $4!$ yields

$$G^{(4)} = 4! \times \frac{1}{48} 3 \text{ (triangle with one external line) } . \quad (3.621)$$

3.22.5 Generating Functional for Vertex Functions. Effective Action

Apart from the connectedness structure, the most important step in economizing the calculation of Feynman diagrams consists in the decomposition of higher connected correlation functions into *one-particle irreducible* vertex functions and one-particle irreducible two-particle correlation functions, from which the full amplitudes can easily be reconstructed. A diagram is called one-particle irreducible if it cannot be decomposed into two disconnected pieces by cutting a single line.

There is, in fact, a simple algorithm which supplies us in general with such a decomposition. For this purpose let us introduce a new generating functional $\Gamma[X]$, to be called the *effective action* of the theory. It is defined via a Legendre transformation of $W[j]$:

$$-\Gamma[X] \equiv W[j] - W_j j. \quad (3.622)$$

Here and in the following, we use a short-hand notation for the functional multiplication, $W_j j = \int d\tau W_j(\tau)j(\tau)$, which considers fields as vectors with a continuous index τ . The new variable X is the functional derivative of $W[j]$ with respect to $j(\tau)$ [recall (3.572)]:

$$X(\tau) \equiv \frac{\delta W[j]}{\delta j(\tau)} \equiv W_{j(\tau)} = \langle x \rangle_{j(\tau)}, \quad (3.623)$$

and thus gives the ground state expectation of the field operator in the presence of the current j . When rewriting (3.622) as

$$-\Gamma[X] \equiv W[j] - X j, \quad (3.624)$$

and functionally differentiating this with respect to X , we obtain the equation

$$\Gamma_X[X] = j. \quad (3.625)$$

This equation shows that the physical path expectation $X(\tau) = \langle x(\tau) \rangle$, where the external current is zero, extremizes the effective action:

$$\Gamma_X[X] = 0. \quad (3.626)$$

We shall study here only physical systems for which the path expectation value is a constant $X(\tau) \equiv X_0$. Thus we shall not consider systems which possess a time-dependent $X_0(\tau)$, although such systems can also be described by x^4 -theories by admitting more general types of gradient terms, for instance $x(\partial^2 - k_0^2)^2 x$. The ensuing τ -dependence of $X_0(\tau)$ may be oscillatory.¹⁷ Thus we shall assume a constant

$$X_0 = \langle x \rangle|_{j=0}, \quad (3.627)$$

which may be zero or non-zero, depending on the phase of the system.

Let us now demonstrate that the effective action contains all the information on the proper vertex functions of the theory. These can be found directly from the functional derivatives:

$$\Gamma^{(n)}(\tau_1, \dots, \tau_n) \equiv \frac{\delta}{\delta X(\tau_1)} \dots \frac{\delta}{\delta X(\tau_n)} \Gamma[X]. \quad (3.628)$$

We shall see that the proper vertex functions are obtained from these functions by a Fourier transform and a simple removal of an overall factor $(2\pi)^D \delta(\sum_{i=1}^n \omega_i)$ to ensure momentum conservation. The functions $\Gamma^{(n)}(\tau_1, \dots, \tau_n)$ will therefore be called *vertex functions*, without the adjective *proper* which indicates the absence of the δ -function. In particular, the Fourier transforms of the vertex functions $\Gamma^{(2)}(\tau_1, \tau_2)$ and $\Gamma^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4)$ are related to their proper versions by

$$\Gamma^{(2)}(\omega_1, \omega_2) = 2\pi\delta(\omega_1 + \omega_2) \bar{\Gamma}^{(2)}(\omega_1), \quad (3.629)$$

$$\Gamma^{(4)}(\omega_1, \omega_2, \omega_3, \omega_4) = 2\pi\delta\left(\sum_{i=1}^4 \omega_i\right) \bar{\Gamma}^{(4)}(\omega_1, \omega_2, \omega_3, \omega_4). \quad (3.630)$$

For the functional derivatives (3.628) we shall use the same short-hand notation as for the functional derivatives (3.572) of $W[j]$, setting

$$\Gamma_{X(\tau_1)\dots X(\tau_n)} \equiv \frac{\delta}{\delta X(\tau_1)} \dots \frac{\delta}{\delta X(\tau_n)} \Gamma[X]. \quad (3.631)$$

The arguments τ_1, \dots, τ_n will usually be suppressed.

In order to derive relations between the derivatives of the effective action and the connected correlation functions, we first observe that the connected one-point function $G_c^{(1)}$ at a nonzero source j is simply the path expectation X [recall (3.581)]:

$$G_c^{(1)} = X. \quad (3.632)$$

¹⁷In higher dimensions there can be crystal- or quasicrystal-like modulations. See, for example, H. Kleinert and K. Maki, *Fortschr. Phys.* **29**, 1 (1981) (<http://www.physik.fu-berlin.de/~kleinert/75>). This paper was the first to investigate in detail icosahedral quasicrystalline structures discovered later in aluminum.

Second, we see that the connected two-point function at a nonzero source j is given by

$$G_c^{(2)} = G_j^{(1)} = W_{jj} = \frac{\delta X}{\delta j} = \left(\frac{\delta j}{\delta X} \right)^{-1} = \Gamma_{XX}^{-1}. \quad (3.633)$$

The inverse symbols on the right-hand side are to be understood in the functional sense, i.e., Γ_{XX}^{-1} denotes the functional matrix:

$$\Gamma_{X(\tau)X(\tau')}^{-1} \equiv \left[\frac{\delta^2 \Gamma}{\delta X(\tau) \delta X(\tau')} \right]^{-1}, \quad (3.634)$$

which satisfies

$$\int d\tau' \Gamma_{X(\tau)X(\tau')}^{-1} \Gamma_{X(\tau')X(\tau'')} = \delta(\tau - \tau''). \quad (3.635)$$

Relation (3.633) states that the second derivative of the effective action determines directly the connected correlation function $G_c^{(2)}(\omega)$ of the interacting theory in the presence of the external source j . Since j is an auxiliary quantity, which eventually be set equal to zero thus making X equal to X_0 , the actual physical propagator is given by

$$G_c^{(2)} \Big|_{j=0} = \Gamma_{XX}^{-1} \Big|_{X=X_0}. \quad (3.636)$$

By Fourier-transforming this relation and removing a δ -function for the overall momentum conservation, the full propagator $G_{\omega^2}(\omega)$ is related to the vertex function $\Gamma^{(2)}(\omega)$, defined in (3.629) by

$$G_{\omega^2}(\omega) \equiv \bar{G}^{(2)}(\mathbf{k}) = \frac{1}{\bar{\Gamma}^{(2)}(\omega)}. \quad (3.637)$$

The third derivative of the generating functional $W[j]$ is obtained by functionally differentiating W_{jj} in Eq. (3.633) once more with respect to j , and applying the chain rule:

$$W_{jjj} = -\Gamma_{XX}^{-2} \Gamma_{XXX} \frac{\delta X}{\delta j} = -\Gamma_{XX}^{-3} \Gamma_{XXX} = -G_c^{(2)^3} \Gamma_{XXX}. \quad (3.638)$$

This equation has a simple physical meaning. The third derivative of $W[j]$ on the left-hand side is the full three-point function at a nonzero source j , so that

$$G_c^{(3)} = W_{jjj} = -G_c^{(2)^3} \Gamma_{XXX}. \quad (3.639)$$

This equation states that the full three-point function arises from a third derivative of $\Gamma[X]$ by attaching to each derivation a full propagator, apart from a minus sign.

We shall express Eq. (3.639) diagrammatically as follows:

$$\text{circle with 3 lines} = \text{circle with 3 lines and a shaded triangle inside}$$

where

$$\text{circle with } n \text{ lines labeled } 1, 2, \dots, n-1, n \equiv G_c^{(n)}$$

denotes the connected n -point function, and

$$\text{shaded circle with } n \text{ lines labeled } 1, 2, \dots, n-1, n \equiv -\Gamma_{X_1 \dots X_n}$$

the negative n -point vertex function.

For the general analysis of the diagrammatic content of the effective action, we observe that according to Eq. (3.638), the functional derivative of the correlation function G with respect to the current j satisfies

$$G_c^{(2)}{}_j = W_{jjj} = G_c^{(3)} = -G_c^{(2)3} \Gamma_{XXX}. \tag{3.640}$$

This is pictured diagrammatically as follows:

$$\frac{\delta}{\delta j} \text{circle with 3 lines} = \text{shaded circle with 3 lines and a shaded triangle inside}. \tag{3.641}$$

This equation may be differentiated further with respect to j in a diagrammatic way. From the definition (3.560) we deduce the trivial recursion relation

$$G_c^{(n)}(\tau_1, \dots, \tau_n) = \frac{\delta}{\delta j(\tau_n)} G_c^{(n-1)}(\tau_1, \dots, \tau_{n-1}), \tag{3.642}$$

which is represented diagrammatically as

$$\text{circle with } n \text{ lines labeled } 1, 2, \dots, n-1, n \equiv \frac{\delta}{\delta j} \text{circle with } n \text{ lines labeled } 1, 2, \dots, n-1, n \quad n > 2.$$

By applying $\delta/\delta j$ repeatedly to the left-hand side of Eq. (3.640), we generate all higher connected correlation functions. On the right-hand side of (3.640), the chain rule leads to a derivative of all correlation functions $G = G_c^{(2)}$ with respect to j , thereby changing a line into a line with an extra three-point vertex as indicated in the diagrammatic equation (3.641). On the other hand, the vertex function Γ_{XXX} must be differentiated with respect to j . Using the chain rule, we obtain for any n -point vertex function:

$$\Gamma_{X \dots X j} = \Gamma_{X \dots X X} \frac{\delta X}{\delta j} = \Gamma_{X \dots X X} G_c^{(2)}, \tag{3.643}$$

which may be represented diagrammatically as

$$\frac{\delta}{\delta j} \begin{array}{c} n \quad n-1 \\ \diagup \quad \diagdown \\ \text{---} \text{---} \\ \text{---} \text{---} \\ \diagdown \quad \diagup \\ 1 \quad 2 \end{array} \text{---} \text{---} \text{---} = \begin{array}{c} n+1 \quad n \quad n-1 \\ \diagup \quad \diagdown \quad \diagup \\ \text{---} \text{---} \text{---} \\ \text{---} \text{---} \\ \diagdown \quad \diagup \\ 1 \quad 2 \end{array} \text{---} \text{---} \text{---} .$$

With these diagrammatic rules, we can differentiate (3.638) any number of times, and derive the diagrammatic structure of the connected correlation functions with an arbitrary number of external legs. The result up to $n = 5$ is shown in Fig. 3.12.

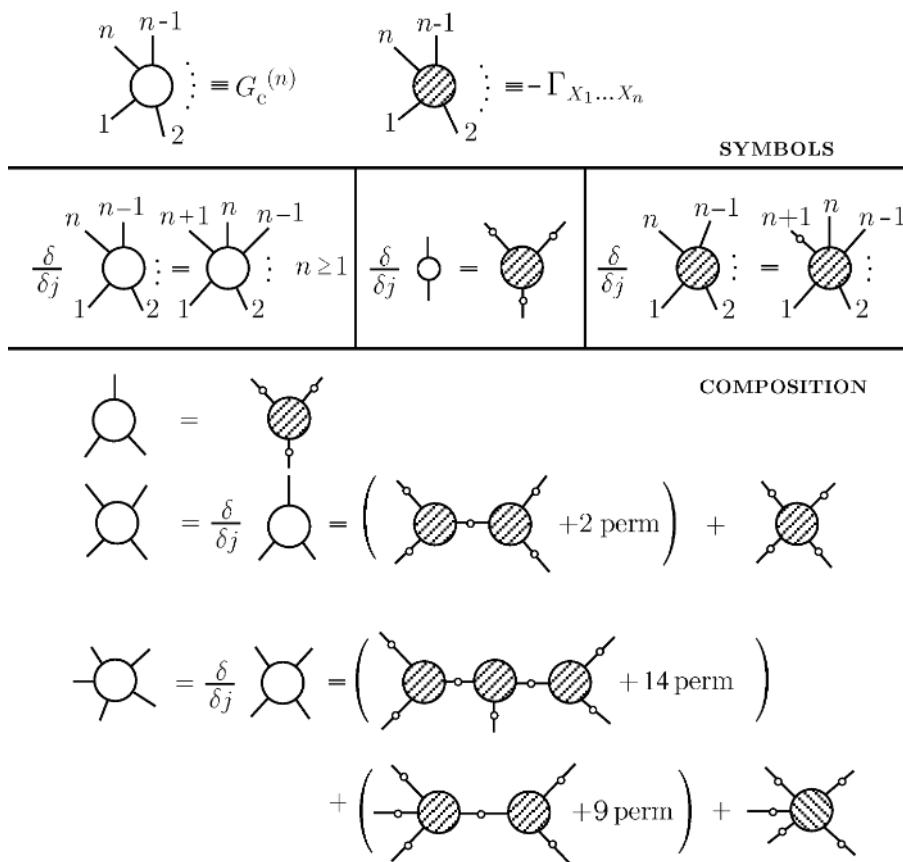

Figure 3.12 Diagrammatic differentiations for deriving tree decomposition of connected correlation functions. The last term in each decomposition yields, after amputation and removal of an overall δ -function of momentum conservation, precisely all one-particle irreducible diagrams.

The diagrams generated in this way have a tree-like structure, and for this reason they are called *tree diagrams*. The tree decomposition reduces all diagrams to their one-particle irreducible contents.

The effective action $\Gamma[X]$ can be used to prove an important composition theorem: The full propagator G can be expressed as a geometric series involving the so-called *self-energy*. Let us decompose the vertex function as

$$\bar{\Gamma}^{(2)} = G_0^{-1} + \bar{\Gamma}_{XX}^{\text{int}}, \quad (3.644)$$

such that the full propagator (3.636) can be rewritten as

$$G = \left(1 + G_0 \bar{\Gamma}_{XX}^{\text{int}}\right)^{-1} G_0. \quad (3.645)$$

Expanding the denominator, this can also be expressed in the form of an integral equation:

$$G = G_0 - G_0 \bar{\Gamma}_{XX}^{\text{int}} G_0 + G_0 \bar{\Gamma}_{XX}^{\text{int}} G_0 \bar{\Gamma}_{XX}^{\text{int}} G_0 - \dots \quad (3.646)$$

The quantity $-\bar{\Gamma}_{XX}^{\text{int}}$ is called the self-energy, commonly denoted by Σ :

$$\Sigma \equiv -\bar{\Gamma}_{XX}^{\text{int}}, \quad (3.647)$$

i.e., the self-energy is given by the interacting part of the second functional derivative of the effective action, except for the opposite sign.

According to Eq. (3.646), all diagrams in G can be obtained from a repetition of self-energy diagrams connected by a single line. In terms of Σ , the full propagator reads, according to Eq. (3.645):

$$G \equiv [G_0^{-1} - \Sigma]^{-1}. \quad (3.648)$$

This equation can, incidentally, be rewritten in the form of an integral equation for the correlation function G :

$$G = G_0 + G_0 \Sigma G. \quad (3.649)$$

3.22.6 Ginzburg-Landau Approximation to Generating Functional

Since the vertex functions are the functional derivatives of the effective action [see (3.628)], we can expand the effective action into a functional Taylor series

$$\Gamma[X] = \sum_{n=0}^{\infty} \frac{1}{n!} \int d\tau_1 \dots d\tau_n \Gamma^{(n)}(\tau_1, \dots, \tau_n) X(\tau_1) \dots X(\tau_n). \quad (3.650)$$

The expansion in the number of loops of the generating functional $\Gamma[X]$ collects systematically the contributions of fluctuations. To zeroth order, all fluctuations are neglected, and the effective action reduces to the initial action, which is the mean-field approximation to the effective action. In fact, in the absence of loop diagrams, the vertex functions contain only the lowest-order terms in $\Gamma^{(2)}$ and $\Gamma^{(4)}$:

$$\Gamma_0^{(2)}(\tau_1, \tau_2) = M \left(-\partial_{\tau_1}^2 + \omega^2 \right) \delta(\tau_1 - \tau_2), \quad (3.651)$$

$$\Gamma_0^{(4)}(\tau_1, \tau_2, \tau_3, \tau_4) = \lambda \delta(\tau_1 - \tau_2) \delta(\tau_1 - \tau_3) \delta(\tau_1 - \tau_4). \quad (3.652)$$

Inserted into (3.650), this yields the zero-loop approximation to $\Gamma[X]$:

$$\Gamma_0[X] = \frac{M}{2!} \int d\tau [(\partial_\tau X)^2 + \omega^2 X^2] + \frac{\lambda}{4!} \int d\tau X^4. \quad (3.653)$$

This is precisely the original action functional (3.562). By generalizing $X(\tau)$ to be a magnetization vector field, $X(\tau) \rightarrow \mathbf{M}(\mathbf{x})$, which depends on the three-dimensional space variables \mathbf{x} rather than the Euclidean time, the functional (3.653) coincides with the phenomenological energy functional set up by Ginzburg and Landau to describe the behavior of magnetic materials near the Curie point, which they wrote as¹⁸

$$\Gamma[\mathbf{M}] = \int d^3x \left[\frac{1}{2} \sum_{i=1}^3 (\partial_i \mathbf{M})^2 + \frac{m^2}{2!} \mathbf{M}^2 + \frac{\lambda}{4!} \mathbf{M}^4 \right]. \quad (3.654)$$

The use of this functional is also referred to as *mean-field theory* or *mean-field approximation* to the full theory.

3.22.7 Composite Fields

Sometimes it is of interest to study also correlation functions in which two fields coincide at one point, for instance

$$G^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = \frac{1}{2} \langle x^2(\tau) x(\tau_1) \cdots x(\tau_n) \rangle. \quad (3.655)$$

If multiplied by a factor $M\omega^2$, the composite operator $M\omega^2 x^2(\tau)/2$ is precisely the frequency term in the action energy functional (3.562). For this reason one speaks of a *frequency insertion*, or, since in the Ginzburg-Landau action (3.654) the frequency ω is denoted by the mass symbol m , one speaks of a *mass insertion* into the correlation function $G^{(n)}(\tau_1, \dots, \tau_n)$.

Actually, we shall never make use of the full correlation function (3.655), but only of the integral over τ in (3.655). This can be obtained directly from the generating functional $Z[j]$ of all correlation functions by differentiation with respect to the square mass in addition to the source terms

$$\int d\tau G^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = -Z^{-1} \frac{\partial}{M\partial\omega^2} \frac{\delta}{\delta j(\tau_1)} \cdots \frac{\delta}{\delta j(\tau_n)} Z[j] \Big|_{j=0}. \quad (3.656)$$

By going over to the generating functional $W[j]$, we obtain in a similar way the connected parts:

$$\int d\tau G_c^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = -\frac{\partial}{M\partial\omega^2} \frac{\delta}{\delta j(\tau_1)} \cdots \frac{\delta}{\delta j(\tau_n)} W[j] \Big|_{j=0}. \quad (3.657)$$

¹⁸L.D. Landau, J.E.T.P. 7, 627 (1937).

The right-hand side can be rewritten as

$$\int d\tau G_c^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = -\frac{\partial}{M\partial\omega^2} G_c^{(n)}(\tau_1, \dots, \tau_n). \quad (3.658)$$

The connected correlation functions $G_c^{(1,n)}(\tau, \tau_1, \dots, \tau_n)$ can be decomposed into tree diagrams consisting of lines and one-particle irreducible vertex functions $\Gamma^{(1,n)}(\tau, \tau_1, \dots, \tau_n)$. If integrated over τ , these are defined from Legendre transform (3.622) by a further differentiation with respect to $M\omega^2$:

$$\int d\tau \Gamma^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = -\frac{\partial}{M\partial\omega^2} \frac{\delta}{\delta X(\tau_1)} \cdots \frac{\delta}{\delta X(\tau_n)} \Gamma[X] \Big|_{X_0}, \quad (3.659)$$

implying the relation

$$\int d\tau \Gamma^{(1,n)}(\tau, \tau_1, \dots, \tau_n) = -\frac{\partial}{M\partial\omega^2} \Gamma^{(n)}(\tau_1, \dots, \tau_n). \quad (3.660)$$

3.23 Path Integral Calculation of Effective Action by Loop Expansion

Path integrals give the most direct access to the effective action of a theory avoiding the cumbersome Legendre transforms. The derivation will proceed diagrammatically loop by loop, which will turn out to be organized by the powers of the Planck constant \hbar . This will now be kept explicit in all formulas. For later applications to quantum mechanics we shall work with real time.

3.23.1 General Formalism

Consider the generating functional of all Green functions

$$Z[j] = e^{iW[j]/\hbar}, \quad (3.661)$$

where $W[j]$ is the generating functional of all *connected* Green functions. The vacuum expectation of the field, the average

$$X(t) \equiv \langle x(t) \rangle, \quad (3.662)$$

is given by the first functional derivative

$$X(t) = \delta W[j] / \delta j(t). \quad (3.663)$$

This can be inverted to yield $j(t)$ as a functional of $X(t)$:

$$j(t) = j[X](t), \quad (3.664)$$

which leads to the Legendre transform of $W[j]$:

$$\Gamma[X] \equiv W[j] - \int dt j(t) X(t), \quad (3.665)$$

where the right-hand side is replaced by (3.664). This is the *effective action* of the theory. The effective action for time independent $\mathbf{X}(t) \equiv \mathbf{X}$ defines the *effective potential*

$$V^{\text{eff}}(X) \equiv -\frac{1}{t_b - t_a} \Gamma[X]. \quad (3.666)$$

The first functional derivative of the effective action gives back the current

$$\frac{\delta \Gamma[X]}{\delta X(t)} = -j(t). \quad (3.667)$$

The generating functional of all connected Green functions can be recovered from the effective action by the inverse Legendre transform

$$W[j] = \Gamma[X] + \int dt j(t)X(t). \quad (3.668)$$

We now calculate these quantities from the path integral formula (3.561) for the generating functional $Z[j]$:

$$Z[j] = \int \mathcal{D}x(t) e^{(i/\hbar)\{\mathcal{A}[x] + \int dt j(t)x(t)\}}. \quad (3.669)$$

With (3.661), this amounts to the path integral formula for $\Gamma[X]$:

$$e^{\frac{i}{\hbar}\{\Gamma[X] + \int dt j(t)X(t)\}} = \int \mathcal{D}x(t) e^{(i/\hbar)\{\mathcal{A}[x] + \int dt j(t)x(t)\}}. \quad (3.670)$$

The action quantum \hbar is a measure for the size of quantum fluctuations. Under many physical circumstances, quantum fluctuations are small, which makes it desirable to develop a method of evaluating (3.670) as an expansion in powers of \hbar .

3.23.2 Mean-Field Approximation

For $\hbar \rightarrow 0$, the path integral over the path $x(t)$ in (3.669) is dominated by the classical solution $x_{\text{cl}}(t)$ which extremizes the exponent

$$\left. \frac{\delta \mathcal{A}[x]}{\delta x(t)} \right|_{x=x_{\text{cl}}(t)} = -j(t), \quad (3.671)$$

and is a functional of $j(t)$ which may be written, more explicitly, as $x_{\text{cl}}(t)[j]$. At this level we can identify

$$W[j] = \Gamma[X] + \int dt j(t)X(t) \approx \mathcal{A}[x_{\text{cl}}[j]] + \int dt j(t)x_{\text{cl}}(t)[j]. \quad (3.672)$$

By differentiating $W[j]$ with respect to j , we have from the general first part of Eq. (3.662):

$$X = \frac{\delta W}{\delta j} = \frac{\delta \Gamma}{\delta X} \frac{\delta X}{\delta j} + X + j \frac{\delta X}{\delta j}. \quad (3.673)$$

Inserting the classical equation of motion (3.671), this becomes

$$X = \frac{\delta \mathcal{A}}{\delta x_{\text{cl}}} \frac{\delta x_{\text{cl}}}{\delta j} + x_{\text{cl}} + j \frac{\delta x_{\text{cl}}}{\delta j} = x_{\text{cl}}. \quad (3.674)$$

Thus, to this approximation, $X(t)$ coincides with the classical path $x_{\text{cl}}(t)$. Replacing $x_{\text{cl}}(t) \rightarrow X(t)$ on the right-hand side of Eq. (3.672), we obtain the lowest-order result, which is of zeroth order in \hbar , the classical approximation to the effective action:

$$\Gamma_0[X] = \mathcal{A}[X]. \quad (3.675)$$

For an anharmonic oscillator in N dimensions with unit mass and an interaction \mathbf{x}^4 , where $\mathbf{x} = (x_1, \dots, x_N)$, which is symmetric under N -dimensional rotations $O(N)$, the lowest-order effective action reads

$$\Gamma_0[\mathbf{X}] = \int dt \left[\frac{1}{2} (\dot{X}_a^2 - \omega^2 X_a^2) - \frac{g}{4!} (X_a^2)^2 \right], \quad (3.676)$$

where repeated indices a, b, \dots are summed from 1 to N following Einstein's summation convention. The effective potential (3.666) is simply the initial potential

$$V_0^{\text{eff}}(\mathbf{X}) = V(\mathbf{X}) = \frac{\omega^2}{2} X_a^2 + \frac{g}{4!} (X_a^2)^2. \quad (3.677)$$

For $\omega^2 > 0$, this has a minimum at $\mathbf{X} \equiv \mathbf{0}$, and there are only two non-vanishing vertex functions $\Gamma^{(n)}(t_1, \dots, t_n)$:

For $n = 2$:

$$\begin{aligned} \Gamma^{(2)}(t_1, t_2)_{ab} &\equiv \left. \frac{\delta^2 \Gamma}{\delta X_a(t_1) \delta X_b(t_2)} \right|_{X_a=0} = \left. \frac{\delta^2 \mathcal{A}}{x_a(t_1) x_b(t_2)} \right|_{x_a=X_a=0} \\ &= (-\partial_t^2 - \omega^2) \delta_{ab} \delta(t_1 - t_2). \end{aligned} \quad (3.678)$$

This determines the inverse of the propagator:

$$\Gamma^{(2)}(t_1, t_2)_{ab} = [i\hbar G^{-1}]_{ab}(t_1, t_2). \quad (3.679)$$

Thus we find to this zeroth-order approximation that $G_{ab}(t_1, t_2)$ is equal to the free propagator:

$$G_{ab}(t_1, t_2) = G_{0ab}(t_1, t_2). \quad (3.680)$$

For $n = 4$:

$$\Gamma^{(4)}(t_1, t_2, t_3, t_4)_{abcd} \equiv \frac{\delta^4 \Gamma}{\delta X_a(t_1) \delta X_b(t_2) \delta X_c(t_3) \delta X_d(t_4)} = g T_{abcd}, \quad (3.681)$$

with

$$T_{abcd} = \frac{1}{3} (\delta_{ab} \delta_{cd} + \delta_{ac} \delta_{bd} + \delta_{ad} \delta_{bc}). \quad (3.682)$$

According to the definition of the effective action, all diagrams of the theory can be composed from the propagator $G_{ab}(t_1, t_2)$ and this vertex via tree diagrams. Thus we see that in this lowest approximation, we recover precisely the subset of all original Feynman diagrams with a tree-like topology. These are all diagrams which do not involve any loops. Since the limit $\hbar \rightarrow 0$ corresponds to the classical equations of motion with no quantum fluctuations we conclude: Classical theory corresponds to tree diagrams.

For $\omega^2 < 0$ the discussion is more involved since the minimum of the potential (3.677) lies no longer at $\mathbf{X} = \mathbf{0}$, but at a nonzero vector \mathbf{X}_0 with an arbitrary direction, and a length

$$|\mathbf{X}_0| = \sqrt{-6\omega^2/g}. \quad (3.683)$$

The second functional derivative (3.678) at \mathbf{X} is anisotropic and reads

Figure 3.13 Effective potential for $\omega^2 > 0$ and $\omega^2 < 0$ in mean-field approximation, pictured for the case of two components X_1, X_2 . The right-hand figure looks like a Mexican hat or the bottom of a champagne bottle..

$$\begin{aligned} \Gamma^{(2)}(t_1, t_2)_{ab} &\equiv \left. \frac{\delta^2 \Gamma}{\delta X_a(t_1) \delta X_b(t_2)} \right|_{X_a \neq 0} = \left. \frac{\delta^2 \mathcal{A}}{x_a(t_1) x_b(t_2)} \right|_{x_a = X_a \neq 0} \\ &= \left[-\partial_t^2 - \omega^2 - \frac{g}{6} (\delta_{ab} X_c^2 + 2X_a X_b) \right] \delta(t_1 - t_2). \end{aligned} \quad (3.684)$$

This is conveniently separated into longitudinal and transversal derivatives with respect to the direction $\hat{\mathbf{X}} = \mathbf{X}/|\mathbf{X}|$. We introduce associated projection matrices:

$$P_{Lab}(\hat{\mathbf{X}}) = \hat{X}_a \hat{X}_b, \quad P_{Tab}(\hat{\mathbf{X}}) = \delta_{ab} - \hat{X}_a \hat{X}_b, \quad (3.685)$$

and decompose

$$\Gamma^{(2)}(t_1, t_2)_{ab} = \Gamma_L^{(2)}(t_1, t_2)_{ab} P_{Lab}(\hat{\mathbf{X}}) + \Gamma_T^{(2)}(t_1, t_2)_{ab} P_{Tab}(\hat{\mathbf{X}}), \quad (3.686)$$

where

$$\Gamma_T^{(2)}(t_1, t_2)_{ab} = \left[-\partial_t^2 - \left(\omega^2 + \frac{g}{6} \mathbf{X}^2 \right) \right] \delta(t_1 - t_2), \quad (3.687)$$

and

$$\Gamma_L^{(2)}(t_1, t_2)_{ab} = \left[-\partial_t^2 - \left(\omega^2 + 3\frac{g}{6} \mathbf{X}^2 \right) \right] \delta(t_1 - t_2). \quad (3.688)$$

This can easily be inverted to find the propagator

$$\mathcal{G}(t_1, t_2)_{ab} = i\hbar \left[\Gamma^{(2)}(t_1, t_2) \right]_{ab}^{-1} = \mathcal{G}_L(t_1, t_2)_{ab} P_{Lab}(\hat{\mathbf{X}}) + \mathcal{G}_T(t_1, t_2)_{ab} P_{Tab}(\hat{\mathbf{X}}), \quad (3.689)$$

where

$$\mathcal{G}_L(t_1, t_2)_{ab} = \frac{i\hbar}{\Gamma_L(t_1, t_2)} = \frac{i\hbar}{-\partial_t^2 - \omega_L^2(\mathbf{X})}, \quad (3.690)$$

$$\mathcal{G}_T(t_1, t_2)_{ab} = \frac{i\hbar}{\Gamma_T^{(2)}(t_1, t_2)} = \frac{i\hbar}{-\partial_t^2 - \omega_T^2(\mathbf{X})} \quad (3.691)$$

are the longitudinal and transversal parts of the Green function. For convenience, we have introduced the \mathbf{X} -dependent frequencies of the longitudinal and transversal Green functions:

$$\omega_L^2(\mathbf{X}) \equiv \omega^2 + 3\frac{g}{6} \mathbf{X}^2, \quad \omega_T^2(\mathbf{X}) \equiv \omega^2 + \frac{g}{6} \mathbf{X}^2. \quad (3.692)$$

To emphasize the fact that this propagator is a functional of \mathbf{X} we represent it by the calligraphic letter \mathcal{G} . For $\omega^2 > 0$, we perform the fluctuation expansion around the minimum of the potential (3.666) at $\mathbf{X} = 0$, where the two Green functions coincide, both having the same frequency ω :

$$\mathcal{G}_L(t_1, t_2)_{ab} |_{\mathbf{X}=0} = \mathcal{G}_T(t_1, t_2)_{ab} |_{\mathbf{X}=0} = \mathcal{G}(t_1, t_2)_{ab} |_{\mathbf{X}=0} = \frac{i\hbar}{-\partial_t^2 - \omega^2}, \quad (3.693)$$

For $\omega^2 < 0$, however, where the minimum lies at the vector \mathbf{X}_0 of length (3.683), they are different:

$$\mathcal{G}_L(t_1, t_2)_{ab} |_{\mathbf{X}=\mathbf{x}_0} = \frac{i\hbar}{-\partial_t^2 + 2\omega^2}, \quad \mathcal{G}_T(t_1, t_2)_{ab} |_{\mathbf{X}=\mathbf{x}_0} = \frac{i\hbar}{-\partial_t^2}. \quad (3.694)$$

Since the curvature of the potential at the minimum in radial direction of \mathbf{X} is positive at the minimum, the longitudinal part has now the positive frequency $-2\omega^2$. The movement along the valley of the minimum, on the other hand, does not increase the energy. For this reason, the transverse part has zero frequency. This feature, observed here in lowest order of the fluctuation expansion, is a very general one, and can be found in the effective action to any loop order. In quantum field theory, there exists a theorem asserting this called *Nambu-Goldstone theorem*. It states that if a quantum field theory without long-range interactions has a continuous symmetry which is broken by a nonzero expectation value of the field corresponding to the present \mathbf{X} [recall (3.662)], then the fluctuations transverse to it have a zero

mass. They are called *Nambu-Goldstone modes* or, because of their bosonic nature, *Nambu-Goldstone bosons*. The exclusion of long-range interactions is necessary, since these can mix with the zero-mass modes and make it massive. This happens, for example, in a superconductor where they make the magnetic field massive, giving it a finite penetration depth, the famous *Meissner effect*. One expresses this pictorially by saying that the long-range mode can eat up the Nambu-Goldstone modes and become massive. The same mechanism is used in elementary particle physics to explain the mass of the W^\pm and Z^0 vector bosons as a consequence of having eaten up a would be Nambu-Goldstone boson of an auxiliary Higgs-field theory.

In quantum-mechanical systems, however, a nonzero expectation value with the associated zero frequency mode in the transverse direction is found only as an artifact of perturbation theory. If all fluctuation corrections are summed, the minimum of the effective potential lies always at the origin. For example, it is well known, that the ground state wave functions of a particle in a double-well potential is symmetric, implying a zero expectation value of the particle position. This symmetry is caused by quantum-mechanical tunneling, a phenomenon which will be discussed in detail in Chapter 17. This phenomenon is of a nonperturbative nature which cannot be described by an effective potential calculated order by order in the fluctuation expansion. Such a potential does, in general, possess a nonzero minimum at some \mathbf{X}_0 somewhere near the zero-order minimum (3.683). Due to this shortcoming, it is possible to derive the Nambu-Goldstone theorem from the quantum-mechanical effective action in the loop expansion, even though the nonzero expectation value \mathbf{X}_0 assumed in the derivation of the zero-frequency mode does not really exist in quantum mechanics. The derivation will be given in Section 3.24.

The use of the initial action to approximate the effective action neglecting corrections caused by the fluctuations is referred to as *mean-field approximation*.

3.23.3 Corrections from Quadratic Fluctuations

In order to find the first \hbar -correction to the mean-field approximation we expand the action in powers of the fluctuations of the paths around the classical solution

$$\delta x(t) \equiv x(t) - x_{\text{cl}}(t), \quad (3.695)$$

and perform a perturbation expansion. The quadratic term in $\delta x(t)$ is taken to be the free-particle action, the higher powers in $\delta x(t)$ are the interactions. Up to second order in the fluctuations $\delta x(t)$, the action is expanded as follows:

$$\begin{aligned} \mathcal{A}[x_{\text{cl}} + \delta x] &+ \int dt j(t) [x_{\text{cl}}(t) + \delta x(t)] \\ &= \mathcal{A}[x_{\text{cl}}] + \int dt j(t) x_{\text{cl}}(t) + \int dt \left\{ j(t) + \frac{\delta \mathcal{A}}{\delta x(t)} \Big|_{x=x_{\text{cl}}} \right\} \delta x(t) \\ &+ \frac{1}{2} \int dt dt' \delta x(t) \frac{\delta^2 \mathcal{A}}{\delta x(t) \delta x(t')} \Big|_{x=x_{\text{cl}}} \delta x(t') + \mathcal{O}((\delta x)^3). \end{aligned} \quad (3.696)$$

The curly bracket multiplying the linear terms in the variation $\delta x(t)$ vanish due to the extremality property of the classical path x_{cl} expressed by the equation of motion (3.671). Inserting this expansion into (3.670), we obtain the approximate expression

$$Z[j] \approx e^{(i/\hbar)\{\mathcal{A}[x_{\text{cl}}] + \int dt j(t)x_{\text{cl}}(t)\}} \int \mathcal{D}\delta x \exp \left\{ \frac{i}{\hbar} \int dt dt' \delta x(t) \frac{\delta^2 \mathcal{A}}{\delta x(t)\delta x(t')} \Big|_{x=x_{\text{cl}}} \delta x(t') \right\}. \quad (3.697)$$

We now observe that the fluctuations $\delta x(t)$ will be of average size $\sqrt{\hbar}$ due to the \hbar -denominator in the Fresnel exponent. Thus the fluctuations $(\delta x)^n$ are of average size $\sqrt{\hbar}^n$. The approximate path integral (3.697) is of the Fresnel type and may be integrated to yield

$$\begin{aligned} & e^{(i/\hbar)\{\mathcal{A}[x_{\text{cl}}] + \int dt j(t)x_{\text{cl}}(t)\}} \left[\det \frac{\delta^2 \mathcal{A}}{\delta x(t)\delta x(t')} \Big|_{x=x_{\text{cl}}} \right]^{-1/2} \\ &= e^{(i/\hbar)\{\mathcal{A}[x_{\text{cl}}] + \int dt j(t)x_{\text{cl}}(t) + i(\hbar/2)\text{Tr} \log[\delta^2 \mathcal{A}/\delta x(t)\delta x(t')]_{x=x_{\text{cl}}}\}}. \end{aligned} \quad (3.698)$$

Comparing this with the left-hand side of (3.670), we find that to first order in \hbar , the effective action may be recovered by equating

$$\Gamma[X] + \int dt j(t)X(t) = \mathcal{A}[x_{\text{cl}}[j]] + \int dt j(t)x_{\text{cl}}(t)[j] + \frac{i\hbar}{2} \text{Tr} \log \frac{\delta^2 \mathcal{A}[x_{\text{cl}}[j]]}{\delta x(t)\delta x(t')}. \quad (3.699)$$

In the limit $\hbar \rightarrow 0$, the tracelog term disappears and (3.699) reduces to the classical expression (3.672).

To include the \hbar -correction into $\Gamma[X]$, we expand $W[j]$ as

$$W[j] = W_0[j] + \hbar W_1[j] + \mathcal{O}(\hbar^2). \quad (3.700)$$

Correspondingly, the path X differs from X_{cl} by a correction term of order \hbar :

$$X = x_{\text{cl}} + \hbar X_1 + \mathcal{O}(\hbar^2). \quad (3.701)$$

Inserting this into (3.699), we find

$$\begin{aligned} \Gamma[X] + \int dt jX &= \mathcal{A}[X - \hbar X_1] + \int dt jX - \hbar \int dt jX_1 \\ &+ \frac{i}{2} \hbar \text{Tr} \log \frac{\delta^2 \mathcal{A}}{\delta x_a \delta x_b} \Big|_{x=X - \hbar X_1} + \mathcal{O}(\hbar^2). \end{aligned} \quad (3.702)$$

Expanding the action up to the same order in \hbar gives

$$\Gamma[X] = \mathcal{A}[X] - \hbar \int dt \left\{ \frac{\delta \mathcal{A}[X]}{\delta X} + j \right\} X_1 + \frac{i}{2} \hbar \text{Tr} \log \frac{\delta^2 \mathcal{A}}{\delta x_a \delta x_b} \Big|_{x=X} + \mathcal{O}(\hbar^2). \quad (3.703)$$

Due to (3.671), the curly-bracket term is only of order \hbar^2 , so that we find the one-loop form of the effective action

$$\begin{aligned} \Gamma[X] = \Gamma_0[X] + \hbar\Gamma_1[X] &= \int dt \left[\frac{1}{2} \dot{X}^2 - \frac{\omega^2}{2} X_a^2 - \frac{g}{4!} (X_a^2)^2 \right] \\ &+ \frac{i}{2} \hbar \text{Tr} \log \left[-\partial_t^2 - \omega^2 - \frac{g}{6} (\delta_{ab} X_c^2 + 2X_a X_b) \right]. \end{aligned} \quad (3.704)$$

Using the decomposition (3.686), the tracelog term can be written as a sum of transversal and longitudinal parts

$$\begin{aligned} \hbar\Gamma_1[X] &= \frac{i}{2} \hbar \text{Tr} \log \Gamma_L^{(2)}(t_1, t_2)_{ab} + \frac{i}{2} (N-1) \hbar \text{Tr} \log \Gamma_T^{(2)}(t_1, t_2)_{ab} \\ &= \frac{i}{2} \hbar \text{Tr} \log (-\partial_t^2 - \omega_L^2(\mathbf{X})) + \frac{i}{2} (N-1) \hbar \text{Tr} \log (-\partial_t^2 - \omega_T^2(\mathbf{X})). \end{aligned} \quad (3.705)$$

What is the graphical content in the Green functions at this level of approximation? Assuming $\omega^2 > 0$, we find for $\mathbf{j} = 0$ that the minimum lies at $\bar{\mathbf{X}} = \mathbf{0}$, as in the mean-field approximation. Around this minimum, we may expand the tracelog in powers of \mathbf{X} . For the simplest case of a single X -variable, we obtain

$$\begin{aligned} \frac{i}{2} \hbar \text{Tr} \log \left(-\partial_t^2 - \omega^2 - \frac{g}{2} X^2 \right) &= \frac{i}{2} \hbar \text{Tr} \log (-\partial_t^2 - \omega^2) + \frac{i}{2} \hbar \text{Tr} \log \left(1 + \frac{i}{-\partial_t^2 - \omega^2} g \frac{X^2}{2} \right) \\ &= i \frac{\hbar}{2} \text{Tr} \log (-\partial_t^2 - \omega^2) - i \frac{\hbar}{2} \sum_{n=1}^{\infty} \left(-i \frac{g}{2} \right)^n \frac{1}{n} \text{Tr} \left(\frac{i}{-\partial_t^2 - \omega^2} X^2 \right)^n. \end{aligned} \quad (3.706)$$

If we insert

$$G_0 = \frac{i}{-\partial_t^2 - \omega^2}, \quad (3.707)$$

this can be written as

$$i \frac{\hbar}{2} \text{Tr} \log (-\partial_t^2 - \omega^2) - i \frac{\hbar}{2} \sum_{n=1}^{\infty} \left(-i \frac{g}{2} \right)^n \frac{1}{n} \text{Tr} (G_0 X^2)^n. \quad (3.708)$$

More explicitly, the terms with $n = 1$ and $n = 2$ read:

$$\begin{aligned} & -\frac{\hbar}{4} g \int dt dt' \delta(t-t') G_0(t, t') X^2(t') \\ & + i \frac{\hbar}{16} g^2 \int dt dt' dt'' \delta^4(t-t'') G_0(t, t') X^2(t') G_0(t', t'') X^2(t'') + \dots \end{aligned} \quad (3.709)$$

The expansion terms of (3.708) for $n \geq 1$ correspond obviously to the Feynman diagrams (omitting multiplicity factors)

$$\mathcal{A}[x_{\text{cl}}] = \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \text{---} \end{array} \text{---} \text{---} + \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \text{---} \end{array} \text{---} \text{---} + \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \text{---} \end{array} \text{---} \text{---} + \begin{array}{c} \text{---} \\ \diagup \quad \diagdown \\ \text{---} \end{array} \text{---} \text{---} + \dots \quad (3.710)$$

The series (3.708) is therefore a sum of all diagrams with one loop and any number of fundamental X^4 -vertices

To systematize the entire expansion (3.708), the tracelog term is [compare (3.549)] pictured by a single-loop diagram

$$i\frac{\hbar}{2}\text{Tr log}(-\partial_t^2 - \omega^2) = \frac{1}{2} \bigcirc . \quad (3.711)$$

The first two diagrams in (3.710) contribute corrections to the vertices $\Gamma^{(2)}$ and $\Gamma^{(4)}$. The remaining diagrams produce higher vertex functions and lead to more involved tree diagrams. In Fourier space we find from (3.709)

$$\Gamma^{(2)}(q) = q^2 - \omega^2 - \hbar\frac{g}{2} \int \frac{dk}{2\pi} \frac{i}{k^2 - \omega^2 + i\eta} \quad (3.712)$$

$$\Gamma^{(4)}(q_i) = g - i\frac{g^2}{2} \left[\int \frac{dk}{2\pi} \frac{i}{k^2 - \omega^2 + i\eta} \frac{i}{(q_1 + q_2 - k)^2 - \omega^2 + i\eta} + 2 \text{ perm} \right]. \quad (3.713)$$

We may write (3.712) in Euclidean form as

$$\begin{aligned} \Gamma^{(2)}(q) &= -q^2 - \omega^2 - \hbar\frac{g}{2} \int \frac{dk}{2\pi} \frac{1}{k^2 + \omega^2} \\ &= -\left(q^2 + \omega^2 + \hbar\frac{g}{2} \frac{1}{2\omega} \right), \end{aligned} \quad (3.714)$$

$$\Gamma^{(4)}(q_i) = g - \hbar\frac{g^2}{2} [I(q_1 + q_2) + 2 \text{ perm}], \quad (3.715)$$

with the Euclidean two-loop integral

$$I(q_1 + q_2) = \int \frac{dk}{2\pi} \frac{1}{k^2 + \omega^2} \frac{i}{(q_1 + q_2 - k)^2 + \omega^2}, \quad (3.716)$$

to be calculated explicitly in Chapter 10. It is equal to $J((q_1 + q_2)^2)/2\pi$ with the functions $J(z)$ of Eq. (10.259).

For $\omega^2 < 0$ where the minimum of the effective action lies at $\bar{\mathbf{X}} \neq \mathbf{0}$, the expansion of the trace of the logarithm in (3.704) must distinguish longitudinal and transverse parts.

3.23.4 Effective Action to Order \hbar^2

Let us now find the next correction to the effective action.¹⁹ Instead of truncating the expansion (3.696), we keep all terms, reorganizing only the linear and quadratic terms as in (3.697). This yields

$$e^{(i/\hbar)\{\Gamma[X]+jX\}} = e^{i(\hbar/2)W[j]} = e^{(i/\hbar)\{(\mathcal{A}[x_{\text{cl}}]+jx_{\text{cl}})+(i\hbar/2)\text{Tr log } \mathcal{A}_{xx}[x_{\text{cl}}]\}} e^{(i/\hbar)\hbar^2 W_2[x_{\text{cl}}]}. \quad (3.717)$$

¹⁹R. Jackiw, Phys. Rev. D 9, 1687 (1976)

The functional $W_2[x_{\text{cl}}]$ is defined by the path integral over the fluctuations

$$e^{(i/\hbar)\hbar^2 W_2[x_{\text{cl}}]} = \frac{\int \mathcal{D}x \exp \frac{i}{\hbar} \left\{ \frac{1}{2} \delta x \mathcal{D}[x_{\text{cl}}] \delta x + \mathcal{R}[x_{\text{cl}}, \delta x] \right\}}{\int \mathcal{D}\delta x \exp \frac{i}{\hbar} \left\{ \frac{1}{2} \delta x \mathcal{A}_{xx}[x_{\text{cl}}] \delta x \right\}}, \quad (3.718)$$

where $\mathcal{D}[x_{\text{cl}}] \equiv \mathcal{A}_{xx}[x_{\text{cl}}]$ is the second functional derivative of the action at $x = x_{\text{cl}}$. The subscripts x of \mathcal{A}_{xx} denote functional differentiation. For the anharmonic oscillator:

$$\mathcal{D}[x_{\text{cl}}] \equiv \mathcal{A}_{xx}[x_{\text{cl}}] = -\partial_t^2 - \omega^2 - \frac{g}{2} x_{\text{cl}}^2. \quad (3.719)$$

The functional \mathcal{R} collects all unharmonic terms:

$$\begin{aligned} \mathcal{R}[x_{\text{cl}}, \delta x] &= \mathcal{A}[x_{\text{cl}} + \delta x] - \mathcal{A}[x_{\text{cl}}] - \int dt \mathcal{A}_x[x_{\text{cl}}](t) \delta x(t) \\ &\quad - \frac{1}{2} \int dt dt' \delta x(t) \mathcal{A}_{xx}[x_{\text{cl}}](t, t') \delta x(t'). \end{aligned} \quad (3.720)$$

In condensed functional vector notation, we shall write expressions like the last term as

$$\frac{1}{2} \int dt dt' \delta x(t) \mathcal{A}_{xx}[x_{\text{cl}}](t, t') \delta x(t') \rightarrow \frac{1}{2} \delta x \mathcal{A}_{xx}[x_{\text{cl}}] \delta x. \quad (3.721)$$

By construction, \mathcal{R} is at least cubic in δx . The path integral (3.718) may thus be considered as the generating functional Z^{fl} of a fluctuating variable $\delta x(\tau)$ with a propagator

$$\mathcal{G}[x_{\text{cl}}] = i\hbar \{ \mathcal{A}_{xx}[x_{\text{cl}}] \}^{-1} \equiv i\hbar \mathcal{D}^{-1}[x_{\text{cl}}],$$

and an interaction $\mathcal{R}[x_{\text{cl}}, \dot{x}]$, both depending on j via x_{cl} . We know from the previous sections, and will immediately see this explicitly, that $\hbar^2 W_2[x_{\text{cl}}]$ is of order \hbar^2 . Let us write the full generating functional $W[j]$ in the form

$$W[j] = \mathcal{A}[x_{\text{cl}}] + x_{\text{cl}} j + \hbar \Delta_1[x_{\text{cl}}], \quad (3.722)$$

where the last term collects one- and two-loop corrections (in higher-order calculations, of course, also higher loops):

$$\Delta_1[x_{\text{cl}}] = \frac{i}{2} \text{Tr} \log \mathcal{D}[x_{\text{cl}}] + \hbar W_2[x_{\text{cl}}]. \quad (3.723)$$

From (3.722) we find the vacuum expectation value $X = \langle x \rangle$ as the functional derivative

$$X = \frac{\delta W[j]}{\delta j} = x_{\text{cl}} + \hbar \Delta_{1x_{\text{cl}}}[x_{\text{cl}}] \frac{\delta x_{\text{cl}}}{\delta j}, \quad (3.724)$$

implying the correction term X_1 :

$$X_1 = \Delta_{1x_{\text{cl}}}[x_{\text{cl}}] \frac{\delta x_{\text{cl}}}{\delta j}. \quad (3.725)$$

The only explicit dependence of $W[j]$ on j comes from the second term in (3.722). In all others, the j -dependence is due to $x_{\text{cl}}[j]$. We may use this fact to express j as a function of x_{cl} . For this we consider $W[j]$ for a moment as a functional of x_{cl} :

$$W[x_{\text{cl}}] = \mathcal{A}[x_{\text{cl}}] + x_{\text{cl}} j[x_{\text{cl}}] + \hbar \Delta_1[x_{\text{cl}}]. \quad (3.726)$$

The combination $W[x_{\text{cl}}] - jX$ gives us the effective action $\Gamma[X]$ [recall (3.665)]. We therefore express x_{cl} in (3.726) as $X - \hbar X_1 - \mathcal{O}(\hbar^2)$ from (3.701), and re-expand everything around X rather than x_{cl} , yields

$$\begin{aligned} \Gamma[X] &= \mathcal{A}[X] - \hbar \mathcal{A}_X[X] X_1 - \hbar X_1 j[X] + \hbar^2 X_1 j_X[X] X_1 + \frac{1}{2} \hbar^2 X_1 \mathcal{D}[X] X_1 \\ &\quad + \hbar \Delta_1[X] - \hbar^2 \Delta_{1X}[X] X_1 + \mathcal{O}(\hbar^3). \end{aligned} \quad (3.727)$$

Since the action is extremal at x_{cl} , we have

$$\mathcal{A}_X[X - \hbar X_1] = -j[X] + \mathcal{O}(\hbar^2), \quad (3.728)$$

and thus

$$\mathcal{A}_X[X] = -j[X] + \hbar \mathcal{A}_{XX}[X] X_1 + \mathcal{O}(\hbar^2) = -j[X] + \hbar \mathcal{D}[X] X_1 + \mathcal{O}(\hbar^2), \quad (3.729)$$

and therefore:

$$\Gamma[X] = \mathcal{A}[X] + \hbar \Delta_1[X] + \hbar^2 \left\{ -\frac{1}{2} X_1 \mathcal{D}[X] X_1 + X_1 j_X[X] X_1 - \Delta_{1X} X_1 \right\}. \quad (3.730)$$

From (3.725) we see that

$$\frac{\delta j}{\delta x_{\text{cl}}} X_1 = \Delta_{1x_{\text{cl}}}[x_{\text{cl}}]. \quad (3.731)$$

Replacing $x_{\text{cl}} \rightarrow X$ with an error of order \hbar , this implies

$$\frac{\delta j}{\delta X} X = \Delta_{1X}[X] + \mathcal{O}(\hbar). \quad (3.732)$$

Inserting this into (3.730), the last two terms in the curly brackets cancel, and the only remaining \hbar^2 -terms are

$$-\frac{\hbar^2}{2} X_1 \mathcal{D}[X] X_1 + \hbar^2 W_2[X] + \mathcal{O}(\hbar^3). \quad (3.733)$$

From the classical equation of motion (3.671) one has a further equation for $\delta j / \delta x_{\text{cl}}$:

$$\frac{\delta j}{\delta x_{\text{cl}}} = -\mathcal{A}_{xx}[x_{\text{cl}}] = -\mathcal{D}[x_{\text{cl}}]. \quad (3.734)$$

Inserting this into (3.725) and replacing again $x_{\text{cl}} \rightarrow X$, we find

$$X_1 = -\mathcal{D}^{-1}[X] \Delta_{1X}[X] + \mathcal{O}(\hbar). \quad (3.735)$$

We now express $\Delta_{1X}[X]$ via (3.723). This yields

$$\Delta_{1X}[X] = \frac{i}{2} \text{Tr} \left(\mathcal{D}^{-1}[X] \frac{\delta}{\delta X} \mathcal{D}[X] \right) + \hbar W_{2X}[X] + \mathcal{O}(\hbar^2). \quad (3.736)$$

Inserting this into (3.735) and further into (3.730), we find for the effective action the expansion up to the order \hbar^2 :

$$\begin{aligned} \Gamma[X] &= \mathcal{A}[X] + \hbar \Gamma_1[X] + \hbar^2 \Gamma_2[X] \\ &= \mathcal{A}[X] + i \frac{\hbar}{2} \text{Tr} \log \mathcal{D}[X] + \hbar^2 W_2[X] \\ &+ \frac{\hbar^2}{2} \frac{1}{2} \text{Tr} \left(\mathcal{D}^{-1}[X] \frac{\delta}{\delta X} \mathcal{D}[X] \right) \mathcal{D}^{-1}[X] \frac{1}{2} \text{Tr} \left(\mathcal{D}^{-1}[X] \frac{\delta}{\delta X} \mathcal{D}[X] \right). \end{aligned} \quad (3.737)$$

We now calculate $W_2[X]$ to lowest order in \hbar . The remainder $\mathcal{R}[X; x]$ in (3.720) has the expansion

$$\mathcal{R}[X; \delta x] = \frac{1}{3!} \mathcal{A}_{XXX}[X] \delta x \delta x \delta x + \frac{1}{4!} \mathcal{A}_{XXXX}[X] \delta x \delta x \delta x \delta x + \dots \quad (3.738)$$

Being interested only in the \hbar^2 -corrections, we have simply replaced x_{cl} by X . In order to obtain $W_2[X]$, we have to calculate all connected vacuum diagrams for the interaction terms in $\mathcal{R}[X; \delta x]$ with a $\delta x(t)$ -propagator

$$\mathcal{G}[X] = i\hbar \{ \mathcal{A}_{XX}[X] \}^{-1} \equiv i\hbar \mathcal{D}^{-1}[X].$$

Since every contraction brings in a factor \hbar , we can truncate the expansion (3.738) after δx^4 . Thus, the only contributions to $i\hbar W_2[X]$ come from the connected vacuum diagrams

$$\frac{1}{8} \text{---} \text{---} \text{---} + \frac{1}{12} \text{---} \text{---} \text{---} + \frac{1}{8} \text{---} \text{---} \text{---}, \quad (3.739)$$

$\hbar^2 \qquad \qquad \qquad \hbar^2 \qquad \qquad \qquad \hbar^2$

where a line stands now for $\mathcal{G}[X]$, a four-vertex for

$$(i/\hbar) \mathcal{A}_{XXXX}[X] = (i/\hbar) \mathcal{D}_{XX}[X], \quad (3.740)$$

and a three-vertex for

$$(i/\hbar) \mathcal{A}_{XXX}[X] = (i/\hbar) \mathcal{D}_X[X]. \quad (3.741)$$

Only the first two diagrams are one-particle irreducible. As a pleasant result, the third diagram which is one-particle reducible cancels with the last term in (3.737). To see this we write that term more explicitly as

$$\frac{\hbar^2}{8} \mathcal{D}_{X_1 X_2}^{-1} \mathcal{A}_{X_1 X_2 X_3} \mathcal{D}_{X_3 X_3'}^{-1} \mathcal{A}_{X_3' X_1' X_2'} \mathcal{D}_{X_1' X_2'}^{-1}, \quad (3.742)$$

which corresponds precisely to the third diagram in $\Gamma_2[X]$, except for an opposite sign. Note that the diagram has a multiplicity 9.

Thus, at the end, only the one-particle irreducible vacuum diagrams contribute to the \hbar^2 -correction to $\Gamma[X]$:

$$i\Gamma_2[X] = i\frac{3}{4!}\mathcal{D}_{12}^{-1}\mathcal{A}_{X_1X_2X_3X_4}\mathcal{D}_{34}^{-1} + i\frac{1}{4!2}\mathcal{A}_{X_1X_2X_3}\mathcal{D}_{X_1X_1'}^{-1}\mathcal{D}_{X_2X_2'}^{-1}\mathcal{D}_{X_3X_3'}^{-1}\mathcal{A}_{X_1X_2X_3}. \quad (3.743)$$

Their diagrammatic representation is

$$\frac{i}{\hbar}\hbar^2\Gamma_2[X] = \frac{1}{8} \begin{array}{c} \text{---} \circ \text{---} \\ \text{---} \circ \text{---} \end{array} + \frac{1}{12} \begin{array}{c} \text{---} \circ \text{---} \\ \text{---} \circ \text{---} \end{array}. \quad (3.744)$$

The one-particle irreducible nature of the diagrams is found to all orders in \hbar .

3.23.5 Finite-Temperature Two-Loop Effective Action

At finite temperature, and in D dimensions, the expansion proceeds with the imaginary-time versions of the \mathbf{X} -dependent Green functions (3.690) and (3.691)

$$\mathcal{G}_L(\tau_1, \tau_2) = \frac{\hbar}{2M\omega_L} \frac{\cosh(\omega_L|\tau_1 - \tau_2| - \hbar\beta\omega_L/2)}{\sinh(\hbar\beta\omega_L/2)}, \quad (3.745)$$

and

$$\mathcal{G}_T(\tau_1, \tau_2) = \frac{\hbar}{2M\omega_T} \frac{\cosh(\omega_T|\tau_1 - \tau_2| - \hbar\beta\omega_T/2)}{\sinh(\hbar\beta\omega_T/2)}, \quad (3.746)$$

where we have omitted the argument \mathbf{X} in $\omega_L(\mathbf{X})$ and $\omega_T(\mathbf{X})$. Treating here the general rotationally symmetric potential $V(\mathbf{x}) = v(x)$, $x = \sqrt{\mathbf{x}^2}$, the two frequencies are

$$\omega_L^2(\mathbf{X}) \equiv \frac{1}{M}v''(X), \quad \omega_T^2(\mathbf{X}) \equiv \frac{1}{MX}v'(X). \quad (3.747)$$

We also decompose the vertex functions into longitudinal and transverse parts. The three-point vertex is a sum

$$\frac{\partial^3 v(X)}{\partial X_i \partial X_j \partial X_k} = P_{ijk}^L v'''(X) + P_{ijk}^T \left[\frac{v''(X)}{X} - \frac{v'(X)}{X^2} \right], \quad (3.748)$$

with the symmetric tensors

$$P_{ijk}^L \equiv \frac{X_i X_j X_k}{X^3} \quad \text{and} \quad P_{ijk}^T \equiv \delta_{ij} \frac{X_k}{X} + \delta_{ik} \frac{X_j}{X} + \delta_{jk} \frac{X_i}{X} - 3P_{ijk}^L. \quad (3.749)$$

The four-point vertex reads

$$\frac{\partial^4 v(X)}{\partial X_i \partial X_j \partial X_k \partial X_l} = P_{ijkl}^L v^{(4)}(X) + P_{ijkl}^T \frac{v'''(X)}{X} + P_{ijkl}^S \left[\frac{v''(X)}{X^2} - \frac{v'(X)}{X^3} \right], \quad (3.750)$$

with the symmetric tensors

$$P_{ijkl}^L = \frac{X_i X_j X_k X_l}{X^4}, \quad (3.751)$$

$$P_{ijkl}^T = \delta_{ij} \frac{X_k X_l}{X^2} + \delta_{ik} \frac{X_j X_l}{X^2} + \delta_{il} \frac{X_j X_k}{X^2} + \delta_{jk} \frac{X_i X_l}{X^2} + \delta_{jl} \frac{X_i X_k}{X^2} + \delta_{kl} \frac{X_i X_k}{X^2} - 6P_{ijkl}^L, \quad (3.752)$$

$$P_{ijkl}^S = \delta_{ij} \delta_{kl} + \delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk} - 3P_{ijkl}^L - 3P_{ijkl}^T. \quad (3.753)$$

The tensors obey the following relations:

$$\frac{X_i}{X} P_{ijk}^L = P_{jk}^L, \quad \frac{X_i}{X} P_{ijk}^T = P_{jk}^T, \quad (3.754)$$

$$P_{ij}^L P_{ikl}^L = P_{jkl}^L, \quad P_{ij}^T P_{ikl}^T = \frac{X_k}{X} P_{jl}^T + \frac{X_l}{X} P_{jk}^T, \quad P_{ij}^L P_{ikl}^T = \frac{X_j}{X} P_{kl}^T, \quad P_{ij}^T P_{ikl}^L = 0, \quad (3.755)$$

$$P_{hij}^L P_{hkl}^L = P_{ijkl}^L, \quad P_{hij}^T P_{hkl}^T = P_{ij}^T P_{kl}^T + P_{ik}^L P_{jl}^T + P_{il}^L P_{jk}^T + P_{jk}^L P_{il}^T + P_{jl}^L P_{ik}^T, \quad (3.756)$$

$$P_{hij}^L P_{hkl}^T = P_{ij}^L P_{kl}^T, \quad P_{hij}^T P_{hkl}^L = P_{ij}^T P_{kl}^L, \quad P_{ij}^L P_{ijkl}^L = P_{kl}^L, \quad P_{ij}^T P_{ijkl}^T = (D-1) P_{kl}^L, \quad (3.757)$$

$$P_{ij}^L P_{ijkl}^T = P_{kl}^T, \quad P_{ij}^T P_{ijkl}^L = 0, \quad (3.758)$$

$$P_{ij}^L P_{ijkl}^S = -2P_{kl}^T, \quad P_{ij}^T P_{ijkl}^S = (D+1)P_{kl}^T - 2(D-1)P_{kl}^L. \quad (3.759)$$

Instead of the effective action, the diagrammatic expansion (3.744) yields now the free energy

$$(i/\hbar)\Gamma[\mathbf{X}] \rightarrow -\beta F(\mathbf{X}). \quad (3.760)$$

Using the above formulas we obtain immediately the mean field contribution to the free energy

$$-\beta F_{\text{MF}} = - \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{\mathbf{X}}^2 + v(X) \right], \quad (3.761)$$

and the one-loop contribution [from the trace-log term in Eq. (3.737)]:

$$-\beta F_{1\text{-loop}} = -\log [2 \sinh(\hbar\beta\omega_L/2)] - (D-1) \log [2 \sinh(\hbar\beta\omega_T/2)]. \quad (3.762)$$

The first of the two-loop diagrams in (3.744) yields the contribution to the free energy

$$\begin{aligned} -\beta \Delta_1 F_{2\text{-loop}} = & -\beta \left\{ \mathcal{G}_L^2(\tau, \tau) v^{(4)}(X) + (D^2 - 1) \mathcal{G}_T^2(\tau, \tau) \left[\frac{v''(X)}{X^2} - \frac{v'(X)}{X^3} \right] \right. \\ & \left. + 2(D-1) \mathcal{G}_L(\tau, \tau) \mathcal{G}_T(\tau, \tau) \left[\frac{v'''(X)}{X} - \frac{2v''(X)}{X^2} + \frac{2v'(X)}{X^3} \right] \right\}. \end{aligned} \quad (3.763)$$

From the second diagram we obtain the contribution

$$\begin{aligned} -\beta \Delta_2 F_{2\text{-loop}} = & \frac{1}{\hbar^2} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 \left\{ \mathcal{G}_L^3(\tau_1, \tau_2) [v'''(X)]^2 \right. \\ & \left. + 3(D-1) \mathcal{G}_L(\tau_1, \tau_2) \mathcal{G}_T^2(\tau_1, \tau_2) \left[\frac{v''(X)}{X} - \frac{v'(X)}{X^2} \right]^2 \right\}. \end{aligned} \quad (3.764)$$

The explicit evaluation yields

$$\begin{aligned} -\beta \Delta_1 F_{2\text{-loop}} = & -\frac{\hbar^2 \beta}{(2M)^2} \left\{ \frac{1}{\omega_L^2} \coth^2(\hbar\beta\omega_L/2) v^{(4)}(X) \right. \\ & + \frac{D^2 - 1}{\omega_T^2} \coth^2(\hbar\beta\omega_T/2) \left[\frac{v''(X)}{X^2} - \frac{v'(X)}{X^3} \right] \\ & \left. + \frac{2(D-1)}{\omega_L \omega_T} \coth(\hbar\beta\omega_L/2) \coth(\hbar\beta\omega_T/2) \left[\frac{v'''(X)}{X} - \frac{2v''(X)}{X^2} + \frac{2v'(X)}{X^3} \right] \right\}. \end{aligned} \quad (3.765)$$

and

$$\begin{aligned} -\beta \Delta_2 F_{2\text{-loop}} = & \frac{2\hbar^2 \beta}{\omega_L} \frac{1}{(2M\omega_L)^3} [v'''(X)]^2 \left[\frac{1}{3} + \frac{1}{\sinh^2(\hbar\beta\omega_L/2)} \right] \\ & + \frac{6\hbar^2 \beta (D-1)}{2\omega_T + \omega_L} \frac{1}{2M\omega_L} \frac{1}{(2M\omega_T)^2} \left[\frac{v''(X)}{X} - \frac{v'(X)}{X^2} \right]^2 \\ & \times \left[\coth^2(\hbar\beta\omega_T/2) + \frac{\omega_T}{\omega_L} \frac{1}{\sinh^2(\hbar\beta\omega_T/2)} + \frac{\omega_T}{2\omega_T - \omega_L} \frac{\sinh[\hbar\beta(2\omega_T - \omega_L)/2]}{\sinh(\hbar\beta\omega_L/2) \sinh^2(\hbar\beta\omega_T/2)} \right]. \end{aligned} \quad (3.766)$$

In the limit of zero temperature, the effective potential in the free energy becomes

$$\begin{aligned}
V_{\text{eff}}(X) \stackrel{T \rightarrow 0}{=} & v(X) + \frac{\hbar\omega_L}{2} + (D-1)\frac{\hbar\omega_T}{2} + \frac{\hbar^2}{8(2M)^2} \left\{ \frac{1}{\omega_L^2} v^{(4)}(X) \right. \\
& + \frac{D^2-1}{\omega_T^2} \left[\frac{v''(X)}{X^2} - \frac{v'(X)}{X^3} \right] + \frac{2(D-1)}{\omega_L\omega_T} \left[\frac{v'''(X)}{X} - \frac{2v''(X)}{X^2} + \frac{2v'(X)}{X^3} \right] \left. \right\} \\
& - \frac{\hbar^2}{6(2M)^3} \left\{ \frac{1}{3\omega_L^4} [v'''(X)]^2 + \frac{3(D-1)}{2\omega_T + \omega_L} \frac{1}{\omega_L\omega_T^2} \left[\frac{v''(X)}{X} - \frac{v'(X)}{X^2} \right]^2 \right\} + \mathcal{O}(\hbar^3). \quad (3.767)
\end{aligned}$$

For the one-dimensional potential

$$V(x) = \frac{M}{2}\omega^2 x^2 + \frac{g_3}{3!}x^3 + \frac{g_4}{4!}x^4, \quad (3.768)$$

the effective potential becomes, up to two loops,

$$\begin{aligned}
V_{\text{eff}}(X) = & \frac{M}{2}\omega^2 X^2 + g_3 X^3 + g_4 X^4 + \frac{1}{\beta} \log(2 \sinh \hbar\beta\omega/2) + \hbar^2 \frac{g_4}{8(2M\omega)^2} \frac{1}{\tanh^2(\hbar\beta\omega/2)} \\
& - \frac{\hbar^2}{6\omega} \frac{(g_3 + g_4 X)^2}{(2M\omega)^3} \left[\frac{1}{3} + \frac{1}{\sinh^2(\hbar\beta\omega/2)} \right] + \mathcal{O}(\hbar^3), \quad (3.769)
\end{aligned}$$

whose $T \rightarrow 0$ limit is

$$\begin{aligned}
V_{\text{eff}}(X) \stackrel{T \rightarrow 0}{=} & \frac{M}{2}\omega^2 X^2 + \frac{g_3}{3!}X^3 + \frac{g_4}{4!}X^4 + \frac{\hbar\omega}{2} + \hbar^2 \frac{g_4}{8(2M\omega)^2} \\
& - \frac{\hbar^2}{18\omega} \frac{(g_3 + g_4 X)^2}{(2M\omega)^3} + \mathcal{O}(\hbar^3). \quad (3.770)
\end{aligned}$$

If the potential is a polynomial in \mathbf{X} , the effective potential at zero temperature can be solved more efficiently than here and to much higher loop orders with the help of recursion relations. This will be shown in Appendix 3C.5.

3.23.6 Background Field Method for Effective Action

In order to find the rules for the loop expansion to any order, let us separate the total effective action into a sum of the classical action $\mathcal{A}[\mathbf{X}]$ and a term $\Gamma^{\text{fl}}[\mathbf{X}]$ which collects the contribution of all quantum fluctuations:

$$\Gamma[\mathbf{X}] = \mathcal{A}[\mathbf{X}] + \Gamma^{\text{fl}}[\mathbf{X}]. \quad (3.771)$$

To calculate the fluctuation part $\Gamma^{\text{fl}}[\mathbf{X}]$, we expand the paths $\mathbf{x}(t)$ around some arbitrarily chosen background path $\mathbf{X}(t)$:²⁰

$$\mathbf{x}(t) = \mathbf{X}(t) + \delta\mathbf{x}(t), \quad (3.772)$$

and calculate the generating functional $W[\mathbf{j}]$ by performing the path integral over the fluctuations:

$$\exp \left\{ \frac{i}{\hbar} W[\mathbf{j}] \right\} = \int \mathcal{D}\delta\mathbf{x} \exp \left\{ \frac{i}{\hbar} \left(\mathcal{A}[\mathbf{X} + \delta\mathbf{x}] + \mathbf{j}[\mathbf{X}](\mathbf{X} + \delta\mathbf{x}) \right) \right\}. \quad (3.773)$$

²⁰In the theory of fluctuating fields, this is replaced by a more general *background field* which explains the name of the method.

From $W[\mathbf{j}]$ we find a \mathbf{j} -dependent expectation value $\mathbf{X}^{\mathbf{j}} = \langle \mathbf{x} \rangle^{\mathbf{j}}$ as $\mathbf{X}^{\mathbf{j}} = \delta W[\mathbf{j}] / \delta \mathbf{j}$, and the Legendre transform $\Gamma[\mathbf{X}] = W[\mathbf{j}] - \mathbf{j} \mathbf{X}^{\mathbf{j}}$. In terms of $\mathbf{X}^{\mathbf{j}}$, Eq. (3.773) can be rewritten as

$$\exp \left\{ \frac{i}{\hbar} \left(\Gamma[\mathbf{X}^{\mathbf{j}}] + \mathbf{j}[\mathbf{X}^{\mathbf{j}}] \mathbf{X}^{\mathbf{j}} \right) \right\} = \int \mathcal{D}\delta\mathbf{x} \exp \left\{ \frac{i}{\hbar} \left(\mathcal{A}[\mathbf{X} + \delta\mathbf{x}] + \mathbf{j}[\mathbf{X}](\mathbf{X} + \delta\mathbf{x}) \right) \right\}. \quad (3.774)$$

The expectation value $\mathbf{X}^{\mathbf{j}}$ has the property of extremizing $\Gamma[\mathbf{X}]$, i.e., it satisfies the equation

$$\mathbf{j} = - \left. \frac{\delta \Gamma[\mathbf{X}]}{\delta \mathbf{X}} \right|_{\mathbf{X}=\mathbf{X}^{\mathbf{j}}} = -\Gamma_{\mathbf{X}}[\mathbf{X}^{\mathbf{j}}]. \quad (3.775)$$

We now choose \mathbf{j} in such a way that $\mathbf{X}^{\mathbf{j}}$ equals the initially chosen \mathbf{X} , and find

$$\exp \left\{ \frac{i}{\hbar} \Gamma[\mathbf{X}] \right\} = \int \mathcal{D}\delta\mathbf{x} \exp \left(\frac{i}{\hbar} \left\{ \mathcal{A}[\mathbf{X} + \delta\mathbf{x}] - \Gamma_{\mathbf{X}}[\mathbf{X}] \delta\mathbf{x} \right\} \right). \quad (3.776)$$

This is a functional integro-differential equation for the effective action $\Gamma[\mathbf{X}]$ which we can solve perturbatively order by order in \hbar . This is done diagrammatically. The diagrammatic elements are lines representing the propagator (3.689)

$$\text{---} = \mathcal{G}_{ab}[\mathbf{X}] \equiv i\hbar \left[\frac{\delta^2 \mathcal{A}[\mathbf{X}]}{\delta X_a \delta X_b} \right]_{ab}^{-1}, \quad (3.777)$$

and vertices

$$\begin{array}{c} n \quad \quad \quad 6 \\ \quad \quad \quad \cdot \cdot \cdot \\ 1 \text{---} \bullet \text{---} 5 \\ \quad \quad \quad \cdot \cdot \cdot \\ 2 \quad \quad \quad 4 \\ \quad \quad \quad 3 \end{array} = \frac{\delta^n \mathcal{A}[\mathbf{X}]}{\delta X_{a_1} \delta X_{a_2} \dots \delta X_{a_n}}. \quad (3.778)$$

From the explicit calculations in the last two subsections we expect the effective action to be the sum of all one-particle irreducible vacuum diagrams formed with these propagators and vertices. This will now be proved to all orders in perturbation theory.

We introduce an auxiliary generating functional $\tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}]$ which governs the correlation functions of the fluctuations $\delta\mathbf{x}$ around the above fixed background \mathbf{X} :

$$\exp \left\{ i\tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}] / \hbar \right\} \equiv \int \mathcal{D}\delta\mathbf{x} \exp \left(\frac{i}{\hbar} \left\{ \tilde{\mathcal{A}}[\mathbf{X}, \delta\mathbf{x}] + \int dt \tilde{\mathbf{j}}(t) \delta\mathbf{x}(t) \right\} \right), \quad (3.779)$$

with the action of fluctuations

$$\tilde{\mathcal{A}}[\mathbf{X}, \delta\mathbf{x}] = \mathcal{A}[\mathbf{X} + \delta\mathbf{x}] - \mathcal{A}[\mathbf{X}] - \mathcal{A}_{\mathbf{X}}[\mathbf{X}] \delta\mathbf{x}, \quad (3.780)$$

whose expansion in powers of $\delta\mathbf{x}(t)$ starts out with a quadratic term. A source $\tilde{\mathbf{j}}(t)$ is coupled to the fluctuations $\delta\mathbf{x}(t)$. By comparing (3.779) with (3.776) we see that for the special choice of the current

$$\tilde{\mathbf{j}} = -\Gamma_{\mathbf{x}}[\mathbf{X}] + \mathcal{A}_{\mathbf{x}}[\mathbf{X}] = -\tilde{\Gamma}_{\mathbf{x}}[\mathbf{X}], \quad (3.781)$$

the right-hand sides coincide, such that the auxiliary functional $\tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}]$ contains precisely the diagrams in $\Gamma^{\text{fl}}[\mathbf{X}]$ which we want to calculate. We now form the Legendre transform of $\tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}]$, which is an auxiliary effective action with two arguments:

$$\tilde{\Gamma}[\mathbf{X}, \tilde{\mathbf{X}}] \equiv \tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}] - \int dt \tilde{\mathbf{j}} \tilde{\mathbf{X}}, \quad (3.782)$$

with the auxiliary conjugate variable

$$\tilde{\mathbf{X}} = \frac{\delta \tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}]}{\delta \tilde{\mathbf{j}}} = \tilde{\mathbf{X}}[\mathbf{X}, \tilde{\mathbf{j}}]. \quad (3.783)$$

This is the expectation value of the fluctuations $\langle \delta\mathbf{x} \rangle$ in the path integral (3.779). If $\tilde{\mathbf{j}}$ has the value (3.781), this expectation vanishes, i.e. $\tilde{\mathbf{X}} = 0$. The auxiliary action $\tilde{\Gamma}[\mathbf{X}, \mathbf{0}]$ coincides with the fluctuating part $\Gamma^{\text{fl}}[\mathbf{X}]$ of the effective action which we want to calculate.

The functional derivatives of $\tilde{W}[\mathbf{X}, \tilde{\mathbf{j}}]$ with respect to $\tilde{\mathbf{j}}$ yield all connected correlation functions of the fluctuating variables $\delta\mathbf{x}(t)$. The functional derivatives of $\tilde{\Gamma}[\mathbf{X}, \tilde{\mathbf{X}}]$ with respect to $\tilde{\mathbf{X}}$ select from these the one-particle irreducible correlation functions. For $\tilde{\mathbf{X}} = 0$, only vacuum diagrams survive.

Thus we have proved that the full effective action is obtained from the sum of the classical action $\Gamma_0[\mathbf{X}] = \mathcal{A}[\mathbf{X}]$, the one-loop contribution $\Gamma_1[\mathbf{X}]$ given by the trace of the logarithm in Eq. (3.705), the two-loop contribution $\Gamma_2[\mathbf{X}]$ in (3.744), and the sum of all connected one-particle irreducible vacuum diagrams with more than two loops

$$\begin{aligned} \frac{i}{\hbar} \sum_{n \geq 3} i\hbar^n \Gamma_n[\mathbf{X}] = & \frac{1}{8} \text{triple loop} + \frac{1}{12} \text{figure-eight} + \frac{1}{48} \text{figure-eight with internal line} + \frac{1}{16} \text{two loops} \\ & + \frac{1}{8} \text{figure-eight with internal line} + \frac{1}{8} \text{figure-eight with internal line} + \frac{1}{24} \text{figure-eight with internal line} + \frac{1}{16} \text{figure-eight with internal line} . \end{aligned} \quad (3.784)$$

Observe that in the expansion of $\Gamma[X]/\hbar$, each line carries a factor \hbar , whereas each n -point vertex contributes a factor \hbar^{-1} . The contribution of an n -loop diagram to $\Gamma[X]$ is therefore of order \hbar^n . The higher-loop diagrams are most easily generated by a recursive treatment of the type developed in Subsection 3.22.3.

For a harmonic oscillator, the expansion stops after the trace of the logarithm (3.705), and reads simply, in one dimension:

$$\begin{aligned} \Gamma[X] &= \mathcal{A}[X] + \frac{i}{2}\hbar \text{Tr} \log \Gamma^{(2)}(t_b, t_a) \\ &= \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{X}^2 - \frac{M\omega^2}{2} X^2 \right] + \frac{i}{2}\hbar \text{Tr} \log \left(-\partial_t^2 - \omega^2 \right). \end{aligned} \quad (3.785)$$

Evaluating the trace of the logarithm we find for a constant X the effective potential (3.666):

$$V^{\text{eff}}(X) = V(X) - \frac{i}{2(t_b - t_a)} \log\{2\pi i \sin[\omega(t_b - t_a)] / M\omega\}. \quad (3.786)$$

If the boundary conditions are periodic, so that the analytic continuation of the result can be used for quantum statistical calculations, the result is

$$V^{\text{eff}}(X) = V(X) - \frac{i}{(t_b - t_a)} \log\{2i \sin[\omega(t_b - t_a)/2]\}. \quad (3.787)$$

It is important to keep in mind that a line in the above diagrams contains an infinite series of fundamental Feynman diagrams of the original perturbation expansion, as can be seen by expanding the denominators in the propagator \mathcal{G}_{ab} in Eqs. (3.689)–(3.691) in powers of \mathbf{X}^2 . This expansion produces a sum of diagrams which can be obtained from the loop diagrams in the expansion of the trace of the logarithm in (3.710) by cutting the loop.

If the potential is a polynomial in \mathbf{X} , the effective potential at zero temperature can be solved most efficiently to high loop orders with the help of recursion relations. This is shown in detail in Appendix 3C.5.

3.24 Nambu-Goldstone Theorem

The appearance of a zero-frequency mode as a consequence of a nonzero expectation value \mathbf{X} can easily be proved for any continuous symmetry and to all orders in perturbation theory by using the full effective action. To be more specific we consider as before the case of $O(N)$ -symmetry, and perform infinitesimal symmetry transformations on the currents \mathbf{j} in the generating functional $W[\mathbf{j}]$:

$$j_a \rightarrow j_a - i\epsilon_{cd} (L_{cd})_{ab} j_b, \quad (3.788)$$

where L_{cd} are the $N(N-1)/2$ generators of $O(N)$ -rotations with the matrix elements

$$(L_{cd})_{ab} = i(\delta_{ca}\delta_{db} - \delta_{da}\delta_{cb}), \quad (3.789)$$

and ϵ_{ab} are the infinitesimal angles of the rotations. Under these, the generating functional is assumed to be invariant:

$$\delta W[\mathbf{j}] = 0 = \int dt \frac{\delta W[\mathbf{j}]}{\delta j_a(x)} i (L_{cd})_{ab} j_b \epsilon_{cd} = 0. \quad (3.790)$$

Expressing the integrand in terms of Legendre-transformed quantities via Eqs. (3.623) and (3.625), we obtain

$$\int dt X_a(t) i (L_{cd})_{ab} \frac{\delta \Gamma[\mathbf{X}]}{\delta X_b(t)} \epsilon_{cd} = 0. \quad (3.791)$$

This expresses the infinitesimal invariance of the effective action $\Gamma[\mathbf{X}]$ under infinitesimal rotations

$$X_a \rightarrow X_a - i\epsilon_{cd} (L_{cd})_{ab} X_b.$$

The invariance property (3.791) is called the *Ward-Takakashi identity* for the functional $\Gamma[\mathbf{X}]$. It can be used to find an infinite set of equally named identities for all vertex functions by forming all $\Gamma[\mathbf{X}]$ functional derivatives of $\Gamma[\mathbf{X}]$ and setting \mathbf{X} equal to the expectation value at the minimum of $\Gamma[\mathbf{X}]$. The first derivative of $\Gamma[\mathbf{X}]$ gives directly from (3.791) (dropping the infinitesimal parameter ϵ_{cd})

$$\begin{aligned} (L_{cd})_{ab} j_b(t) &= (L_{cd})_{ab} \frac{\delta\Gamma[\mathbf{X}]}{\delta X(t)_b} \\ &= - \int dt' X_{a'}(t') (L_{cd})_{a'b} \frac{\delta^2\Gamma[\mathbf{X}]}{\delta X_b(t')\delta X_n(t)}. \end{aligned} \quad (3.792)$$

Denoting the expectation value at the minimum of the effective potential by $\bar{\mathbf{X}}$, this yields

$$\int dt' \bar{X}_{a'}(t') (L_{cd})_{a'b} \frac{\delta^2\Gamma[\mathbf{X}]}{\delta X_b(t')\delta X_a(t)} \Big|_{\mathbf{X}(t)=\bar{\mathbf{X}}} = 0. \quad (3.793)$$

Now the second derivative is simply the vertex function $\Gamma^{(2)}(t', t)$ which is the functional inverse of the correlation function $G^{(2)}(t', t)$. The integral over t selects the zero-frequency component of the Fourier transform

$$\tilde{\Gamma}^{(2)}(\omega') \equiv \int dt' e^{i\omega' t} \Gamma^{(2)}(t', t). \quad (3.794)$$

If we define the Fourier components of $\Gamma^{(2)}(t', t)$ accordingly, we can write (3.793) in Fourier space as

$$X_{a'}^0 (L_{cd})_{a'b} \tilde{G}_{ba}^{-1}(\omega' = 0) = 0. \quad (3.795)$$

Inserting the matrix elements (3.789) of the generators of the rotations, this equation shows that for $\bar{\mathbf{X}} \neq 0$, the fully interacting transverse propagator has to possess a singularity at $\omega' = 0$. In quantum field theory, this implies the existence of $N - 1$ massless particles, the Nambu-Goldstone boson. The conclusion may be drawn only if there are no massless particles in the theory from the outset, which may be “eaten up” by the Nambu-Goldstone boson, as explained earlier in the context of Eq. (3.691).

As mentioned before at the end of Subsection 3.23.1, the Nambu-Goldstone theorem does not have any consequences for quantum mechanics since fluctuations are too violent to allow for the existence of a nonzero expectation value \mathbf{X} . The effective action calculated to any finite order in perturbation theory, however, is incapable of reproducing this physical property and does have a nonzero extremum and ensuing transverse zero-frequency modes.

3.25 Effective Classical Potential

The loop expansion of the effective action $\Gamma[X]$ in (3.771), consisting of the trace of the logarithm (3.705) and the one-particle irreducible diagrams (3.744), (3.784) and the associated effective potential $V(X)$ in Eq. (3.666), can be continued in a straightforward way to imaginary times setting $t_b - t_a \rightarrow -i\hbar\beta$ to form the Euclidean effective potential $\Gamma_e[X]$. For the harmonic oscillator, where the expansion stops after the trace of the logarithm and the effective potential reduces to the simple expression (3.785), we find the imaginary-time version

$$V^{\text{eff}}(X) = V(X) + \frac{1}{\beta} \log \left(2 \sinh \frac{\beta\hbar\omega}{2} \right). \quad (3.796)$$

Since the effective action contains the effect of all fluctuations, the minimum of the effective potential $V(X)$ should yield directly the full quantum statistical partition function of a system:

$$Z = \exp[-\beta V(X)]_{\text{min}}. \quad (3.797)$$

Inserting the harmonic oscillator expression (3.796) we find indeed the correct result (2.407).

For anharmonic systems, we expect the loop expansion to be able to approximate $V(X)$ rather well to yield a good approximation for the partition function via Eq. (3.797). It is easy to realize that this cannot be true. We have shown in Section 2.9 that for high temperatures, the partition function is given by the integral [recall (2.353)]

$$Z_{\text{cl}} = \int_{-\infty}^{\infty} \frac{dx}{l_e(\hbar\beta)} e^{-V(x)/k_B T}. \quad (3.798)$$

This integral can in principle be treated by the same background field method as the path integral, albeit in a much simpler way. We may write $x = X + \delta x$ and find a loop expansion for an effective potential. This expansion evaluated at the extremum will yield a good approximation to the integral (3.798) only if the potential is very close to a harmonic one. For any more complicated shape, the integral at small β will cover the entire range of x and can therefore only be evaluated numerically. Thus we can never expect a good result for the partition function of anharmonic systems at high temperatures, if it is calculated from Eq. (3.797).

It is easy to find the culprit for this problem. In a one-dimensional system, the correlation functions of the fluctuations around X are given by the correlation function [compare (3.304), (3.251), and (3.690)]

$$\begin{aligned} \langle \delta x(\tau) \delta x(\tau') \rangle &= G_{\Omega^2(X)}^{(2)}(\tau, \tau') = \frac{\hbar}{M} G_{\Omega^2(X),e}^{\text{p}}(\tau - \tau') \\ &= \frac{\hbar}{M} \frac{1}{2\Omega(X)} \frac{\cosh \Omega(X)(|\tau - \tau'| - \hbar\beta/2)}{\sinh[\Omega(X)\hbar\beta/2]}, \quad |\tau - \tau'| \in [0, \hbar\beta], \end{aligned} \quad (3.799)$$

with the X -dependent frequency given by

$$\Omega^2(X) = \omega^2 + 3\frac{g}{6}X^2. \quad (3.800)$$

At equal times $\tau = \tau'$, this specifies the square width of the fluctuations $\delta x(\tau)$:

$$\langle [\delta x(\tau)]^2 \rangle = \frac{\hbar}{M} \frac{1}{2\Omega(X)} \coth \frac{\Omega(X)\hbar\beta}{2}. \quad (3.801)$$

The point is now that for large temperatures T , this width grows linearly in T

$$\langle [\delta x(\tau)]^2 \rangle \xrightarrow{T \rightarrow \infty} \frac{k_B T}{M\Omega^2}. \quad (3.802)$$

The linear behavior follows the historic *Dulong-Petit law* for the classical fluctuation width of a harmonic oscillator [compare with the Dulong-Petit law (2.603) for the thermodynamic quantities]. It is a direct consequence of the *equipartition theorem* for purely thermal fluctuations, according to which the potential energy has an average $k_B T/2$:

$$\frac{M\Omega^2}{2} \langle x^2 \rangle = \frac{k_B T}{2}. \quad (3.803)$$

If we consider the spectral representation (3.248) of the correlation function,

$$G_{\Omega^2, e}^p(\tau - \tau') = \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^2 + \Omega^2} e^{-i\omega_m(\tau - \tau')}, \quad (3.804)$$

we see that the linear growth is entirely due to term with zero Matsubara frequency.

The important observation is now that if we remove this zero frequency term from the correlation function and form the *subtracted correlation function* [recall (3.253)]

$$G_{\Omega^2, e}^{p'}(\tau) \equiv G_{\Omega^2, e}^p(\tau) - \frac{1}{\hbar\beta\Omega^2} = \frac{1}{2\Omega} \frac{\cosh \Omega(|\tau| - \hbar\beta/2)}{\sinh[\Omega\hbar\beta/2]} - \frac{1}{\hbar\beta\Omega^2}, \quad (3.805)$$

we see that the subtracted square width

$$a_{\Omega}^2 \equiv G_{\Omega^2, e}^{p'}(0) = \frac{1}{2\Omega} \coth \frac{\Omega\hbar\beta}{2} - \frac{1}{\hbar\beta\Omega^2} \quad (3.806)$$

decrease for large T . This is shown in Fig. 3.14. Due to this decrease, there exists a method to substantially improve perturbation expansions with the help of the so-called effective classical potential.

3.25.1 Effective Classical Boltzmann Factor

The above considerations lead us to the conclusion that a useful approximation for partition function can be obtained only by expanding the path integral in powers of

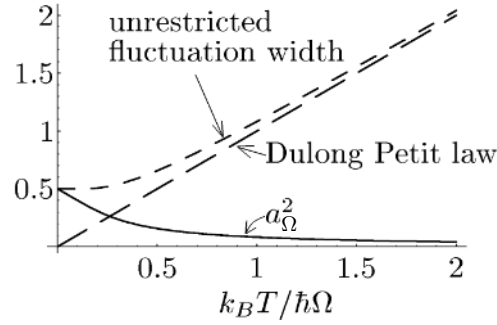

Figure 3.14 Local fluctuation width compared with the unrestricted fluctuation width of harmonic oscillator and its linear Dulong-Petit approximation. The vertical axis shows units of $\hbar/M\Omega$, a quantity of dimension length².

the subtracted fluctuations $\delta'x(\tau)$ which possess no zero Matsubara frequency. The quantity which is closely related to the effective potential $V^{\text{eff}}(X)$ in Eq. (3.666) but allows for a more accurate evaluation of the partition function is the *effective classical potential* $V^{\text{eff cl}}(x_0)$. Just as $V^{\text{eff}}(X)$, it contains the effects of *all* quantum fluctuations, but it keeps separate track of the thermal fluctuations which makes it a convenient tool for numerical treatment of the partition function. The definition starts out similar to the background method in Subsection 3.23.6 in Eq. (3.772). We split the paths as in Eq. (2.443) into a time-independent constant background x_0 and a fluctuation $\eta(\tau)$ with zero temporal average $\bar{\eta} = 0$:

$$x(\tau) = x_0 + \eta(\tau) \equiv x_0 + \sum_{m=1}^{\infty} (x_m e^{i\omega_m \tau} + \text{c.c.}), \quad x_0 = \text{real}, \quad x_{-m} \equiv x_m^*, \quad (3.807)$$

and write the partition function using the measure (2.448) as

$$Z = \oint \mathcal{D}x e^{-\mathcal{A}_e/\hbar} = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar}, \quad (3.808)$$

where

$$\oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar} = \prod_{m=1}^{\infty} \left[\int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{d \text{Re } x_m d \text{Im } x_m}{\pi k_B T / M \omega_m^2} \right] e^{-\mathcal{A}_e/\hbar}. \quad (3.809)$$

Comparison of (2.447) with the integral expression (2.352) for the classical partition function Z_{cl} suggests writing the path integral over the components with nonzero Matsubara frequencies as a Boltzmann factor

$$B(x_0) \equiv e^{-V^{\text{eff cl}}(x_0)/k_B T} \quad (3.810)$$

and defined the quantity $V^{\text{eff cl}}(x_0)$ as the effective classical potential. The full partition function is then given by the integral

$$Z = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-V^{\text{eff cl}}(x_0)/k_B T}, \quad (3.811)$$

where the *effective classical Boltzmann factor* $B(x_0)$ contains all information on the quantum fluctuations of the system and allows to calculate the full quantum statistical partition function from a single classically looking integral. At high-temperature, the partition function (3.811) takes the classical limit (2.462). Thus, by construction, the effective classical potential $V^{\text{eff cl}}(x_0)$ will approach the initial potential $V(x_0)$:

$$V^{\text{eff cl}}(x_0) \xrightarrow{T \rightarrow \infty} V(x_0). \quad (3.812)$$

This is a direct consequence of the shrinking fluctuation width (3.806) for growing temperature.

The path integral representation of the effective classical Boltzmann factor

$$B(x_0) \equiv \oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar} \quad (3.813)$$

can also be written as a path integral in which one has inserted a δ -function to ensure the path average

$$\bar{x} \equiv \frac{1}{\hbar\beta} \int_0^{\hbar\beta} d\tau x(\tau). \quad (3.814)$$

Let us introduce the slightly modified δ -function [recall (2.353)]

$$\tilde{\delta}(\bar{x} - x_0) \equiv l_e(\hbar\beta)\delta(\bar{x} - x_0) = \sqrt{\frac{2\pi\hbar^2\beta}{M}} \delta(\bar{x} - x_0). \quad (3.815)$$

Then we can write

$$\begin{aligned} B(x_0) \equiv e^{-V^{\text{eff cl}}(x_0)/k_B T} &= \oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar} = \oint \mathcal{D}x \tilde{\delta}(\bar{x} - x_0) e^{-\mathcal{A}_e/\hbar} \\ &= \oint \mathcal{D}\eta \tilde{\delta}(\bar{\eta}) e^{-\mathcal{A}_e/\hbar}. \end{aligned} \quad (3.816)$$

As a check we evaluate the effective classical Boltzmann factor for the harmonic action (2.445). With the path splitting (3.807), it reads

$$\mathcal{A}_e[x_0 + \eta] = \hbar\beta \frac{M\omega^2}{2} x_0^2 + \frac{M}{2} \int_0^{\hbar\beta} d\tau \left[\dot{\eta}^2(\tau) + \omega^2 \eta^2(\tau) \right]. \quad (3.817)$$

After representing the δ function by a Fourier integral

$$\tilde{\delta}(\bar{\eta}) = l_e(\hbar\beta) \int_{-i\infty}^{i\infty} \frac{d\lambda}{2\pi i} \exp\left(\lambda \frac{1}{\hbar\beta} \int d\tau \eta(\tau)\right), \quad (3.818)$$

we find the path integral

$$\begin{aligned} B_\omega(x_0) &= \oint \mathcal{D}\eta \tilde{\delta}(\bar{\eta}) e^{-\mathcal{A}_e/\hbar} = e^{-\beta M\omega^2 x_0^2/2} l_e(\hbar\beta) \int_{-i\infty}^{i\infty} \frac{d\lambda}{2\pi i} \\ &\quad \times \oint \mathcal{D}\eta \exp\left\{-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{\eta}^2(\tau) - \frac{\lambda}{\beta} \eta(\tau)\right]\right\}. \end{aligned} \quad (3.819)$$

The path integral over $\eta(\tau)$ in the second line can now be performed without the restriction $\hbar\beta = 0$ and yields, recalling (3.555), (3.556), and inserting there $j(\tau) = \lambda/\beta$, we obtain for the path integral over $\eta(\tau)$ in the second line of (3.819):

$$\frac{1}{2 \sinh(\beta\hbar\omega/2)} \exp \left\{ \frac{\lambda^2}{2M\hbar\beta^2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' G_{\omega^2, e}^p(\tau - \tau') \right\}. \quad (3.820)$$

The integrals over τ, τ' are most easily performed on the spectral representation (3.248) of the correlation function:

$$\int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' G_{\omega^2, e}^p(\tau - \tau') = \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \frac{1}{\hbar\beta} \sum_{m=-\infty}^{\infty} \frac{1}{\omega_m^2 + \omega^2} e^{-i\omega_m(\tau - \tau')} = \frac{\hbar\beta}{\omega^2}. \quad (3.821)$$

The expression (3.820) has to be integrated over λ and yields

$$\frac{1}{2 \sinh(\beta\hbar\omega/2)} \int_{-i\infty}^{i\infty} \frac{d\lambda}{2\pi i} \exp \left(\frac{\lambda^2}{2M\omega^2\beta} \right) = \frac{1}{2 \sinh(\beta\hbar\omega/2)} \frac{1}{l_e(\hbar\beta)} \omega\hbar\beta. \quad (3.822)$$

Inserting this into (3.819) we obtain the local Boltzmann factor

$$B_\omega(x_0) \equiv e^{-V_\omega^{\text{eff cl}}(x_0)/k_B T} = \oint \mathcal{D}\eta \tilde{\delta}(\bar{\eta}) e^{-\mathcal{A}_e/\hbar} = \frac{\beta\hbar\omega/2}{\sinh(\beta\hbar\omega/2)} e^{-\beta M\omega^2 x_0^2}. \quad (3.823)$$

The final integral over x_0 in (3.808) reproduces the correct partition function (2.409) of the harmonic oscillator.

3.25.2 Effective Classical Hamiltonian

It is easy to generalize the expression (3.816) to phase space, where we define the *effective classical Hamiltonian* $H^{\text{eff cl}}(p_0, x_0)$ and the associated Boltzmann factor $B(p_0, x_0)$ by the path integral

$$B(p_0, x_0) \equiv \exp \left[-\beta H^{\text{eff cl}}(p_0, x_0) \right] \equiv \oint \mathcal{D}x \oint \frac{\mathcal{D}p}{2\pi\hbar} \delta(x_0 - \bar{x}) 2\pi\hbar \delta(p_0 - \bar{p}) e^{-\mathcal{A}_e[p, x]/\hbar}, \quad (3.824)$$

where $\bar{x} = \int_0^{\hbar\beta} d\tau x(\tau)/\hbar\beta$ and $\bar{p} = \int_0^{\hbar\beta} d\tau p(\tau)/\hbar\beta$ are the temporal averages of position and momentum, and $\mathcal{A}_e[p, x]$ is the Euclidean action in phase space

$$\mathcal{A}_e[p, x] = \int_0^{\hbar\beta} d\tau [-ip(\tau)\dot{x}(\tau) + H(p(\tau), x(\tau))]. \quad (3.825)$$

The full quantum-mechanical partition function is obtained from the classical-looking expression [recall (2.346)]

$$Z = \int_{-\infty}^{\infty} dx_0 \int_{-\infty}^{\infty} \frac{dp_0}{2\pi\hbar} e^{-\beta H^{\text{eff cl}}(p_0, x_0)}. \quad (3.826)$$

The definition is such that in the classical limit, $H^{\text{eff cl}}(p_0, x_0)$ becomes the ordinary Hamiltonian $H(p_0, x_0)$.

For a harmonic oscillator, the effective classical Hamiltonian can be directly deduced from Eq. (3.823) by “undoing” the p_0 -integration:

$$B_\omega(p_0, x_0) \equiv e^{-H_\omega^{\text{eff cl}}(p_0, x_0)/k_B T} = l_e(\hbar\beta) \frac{\beta\hbar\omega/2}{\sinh(\beta\hbar\omega/2)} e^{-\beta(p_0^2/2M + M\omega^2 x_0^2)}. \quad (3.827)$$

Indeed, inserting this into (3.826), we recover the harmonic partition function (2.409).

Consider a particle in three dimensions moving in a constant magnetic field B along the z -axis. For the sake of generality, we allow for an additional harmonic oscillator centered at the origin with frequencies ω_\parallel in z -direction and ω_\perp in the xy -plane (as in Section 2.19). It is then easy to calculate the effective classical Boltzmann factor for the Hamiltonian [recall (2.689)]

$$H(\mathbf{p}, \mathbf{x}) = \frac{1}{2M} \mathbf{p}^2 + \frac{M}{2} \omega_\perp^2 \mathbf{x}_\perp^2(\tau) + \frac{M}{2} \omega_\parallel^2 z^2(\tau) + \omega_B l_z(\mathbf{p}(\tau), \mathbf{x}(\tau)), \quad (3.828)$$

where $l_z(\mathbf{p}, \mathbf{x})$ is the z -component of the angular momentum defined in Eq. (2.647). We have shifted the center of momentum integration to \mathbf{p}_0 , for later convenience (see Subsection 5.11.2). The vector $\mathbf{x}^\perp = (x, y)$ denotes the orthogonal part of \mathbf{x} . As in the generalized magnetic field action (2.689), we have chosen different frequencies in front of the harmonic oscillator potential and of the term proportional to l_z , for generality. The effective classical Boltzmann factor follows immediately from (2.703) by “undoing” the momentum integrations in p_x, p_y , and using (3.827) for the motion in the z -direction:

$$B(\mathbf{p}_0, \mathbf{x}_0) = e^{-\beta H^{\text{eff cl}}(\mathbf{p}_0, \mathbf{x}_0)} = l_e^3(\hbar\beta) \frac{\hbar\beta\omega_+/2}{\sinh \hbar\beta\omega_+/2} \frac{\hbar\beta\omega_-/2}{\sinh \hbar\beta\omega_-/2} \frac{\hbar\beta\omega_\parallel/2}{\sinh \hbar\beta\omega_\parallel/2} e^{-\beta H(\mathbf{p}_0, \mathbf{x}_0)}, \quad (3.829)$$

where $\omega_\pm \equiv \omega_B \pm \omega_\perp$, as in (2.699). As in Eq. (3.823), the restrictions of the path integrals over \mathbf{x} and \mathbf{p} to the fixed averages $\mathbf{x}_0 = \bar{\mathbf{x}}$ and $\mathbf{p}_0 = \bar{\mathbf{p}}$ give rise to the extra numerators in comparison to (2.703).

3.25.3 High- and Low-Temperature Behavior

We have remarked before in Eq. (3.812) that in the limit $T \rightarrow \infty$, the effective classical potential $V^{\text{eff cl}}(x_0)$ converges by construction against the initial potential $V(x_0)$. There exists, in fact, a well-defined power series in $\hbar\omega/k_B T$ which describes this approach. Let us study this limit explicitly for the effective classical potential of the harmonic oscillator calculated in (3.823), after rewriting it as

$$\begin{aligned} V_\omega^{\text{eff cl}}(x_0) &= k_B T \log \frac{\sinh(\hbar\omega/2k_B T)}{\hbar\omega/2k_B T} + \frac{M}{2} \omega^2 x_0^2 \\ &= \frac{M}{2} \omega^2 x_0^2 + \frac{\hbar\omega}{2} + k_B T \left[\log(1 - e^{-\hbar\omega/k_B T}) - \log \frac{\hbar\omega}{k_B T} \right]. \end{aligned} \quad (3.830)$$

Due to the subtracted logarithm of ω in the brackets, the effective classical potential has a power series

$$V_{\omega}^{\text{eff cl}}(x_0) = \frac{M}{2}\omega^2 x_0^2 + \hbar\omega \left[\frac{1}{24} \frac{\hbar\omega}{k_B T} - \frac{1}{2880} \left(\frac{\hbar\omega}{k_B T} \right)^3 + \dots \right]. \quad (3.831)$$

This pleasant high-temperature behavior is in contrast to that of the effective potential which reads for the harmonic oscillator

$$\begin{aligned} V_{\omega}^{\text{eff}}(x_0) &= k_B T \log [2 \sinh(\hbar\omega/2k_B T)] + \frac{M}{2}\omega^2 x_0^2 \\ &= \frac{M}{2}\omega^2 x_0^2 + \frac{\hbar\omega}{2} + k_B T \log(1 - e^{-\hbar\omega/k_B T}), \end{aligned} \quad (3.832)$$

as we can see from (3.796). The logarithm of ω prevents this from having a power series expansion in $\hbar\omega/k_B T$, reflecting the increasing width of the unsubtracted fluctuations.

Consider now the opposite limit $T \rightarrow 0$, where the final integral over the Boltzmann factor $B(x_0)$ can be calculated exactly by the saddle-point method. In this limit, the effective classical potential $V_{\omega}^{\text{eff cl}}(x_0)$ coincides with the Euclidean version of the effective potential:

$$V_{\omega}^{\text{eff cl}}(x_0) \xrightarrow{T \rightarrow 0} V_{\omega}^{\text{eff}}(x_0) \equiv \Gamma_e[X]/\beta \Big|_{X=x_0}, \quad (3.833)$$

whose real-time definition was given in Eq. (3.666).

Let us study this limit again explicitly for the harmonic oscillator, where it becomes

$$V_{\omega}^{\text{eff cl}}(x_0) \xrightarrow{T \rightarrow 0} \frac{\hbar\omega}{2} + \frac{M}{2}\omega^2 x_0^2 - k_B T \log \frac{\hbar\omega}{k_B T}, \quad (3.834)$$

i.e., the additional constant tends to $\hbar\omega/2$. This is just the quantum-mechanical zero-point energy which guarantees the correct low-temperature limit

$$\begin{aligned} Z_{\omega} &\xrightarrow{T \rightarrow 0} e^{-\hbar\omega/2k_B T} \frac{\hbar\omega}{k_B T} \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-M\omega^2 x_0^2/2k_B T} \\ &= e^{-\hbar\omega/2k_B T}. \end{aligned} \quad (3.835)$$

The limiting partition function is equal to the Boltzmann factor with the zero-point energy $\hbar\omega/2$.

3.25.4 Alternative Candidate for Effective Classical Potential

It is instructive to compare this potential with a related expression which can be defined in terms of the partition function density defined in Eq. (2.332):

$$\tilde{V}_{\omega}^{\text{eff cl}}(x) \equiv k_B T \log [l_e(\hbar\beta) z(x)]. \quad (3.836)$$

This quantity shares with $V_\omega^{\text{eff cl}}(x_0)$ the property that it also yields the partition function by forming the integral [compare (2.331)]:

$$Z = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-\tilde{V}^{\text{eff cl}}(x_0)/k_B T}. \quad (3.837)$$

It may therefore be considered as an alternative candidate for an effective classical potential.

For the harmonic oscillator, we find from Eq. (2.333) the explicit form

$$\tilde{V}_\omega^{\text{eff cl}}(x) = -\frac{k_B T}{2} \log \frac{2\hbar\omega}{k_B T} + \frac{\hbar\omega}{2} + k_B T \left[\log \left(1 - e^{-2\hbar\omega/k_B T} \right) + \frac{M\omega}{\hbar} \tanh \frac{\hbar\omega}{k_B T} x^2 \right]. \quad (3.838)$$

This shares with the effective potential $V^{\text{eff}}(X)$ in Eq. (3.832) the unpleasant property of possessing no power series representation in the high-temperature limit.

The low-temperature limit of $\tilde{V}_\omega^{\text{eff cl}}(x)$ looks at first sight quite similar to (3.834):

$$\tilde{V}_\omega^{\text{eff cl}}(x_0) \xrightarrow{T \rightarrow 0} \frac{\hbar\omega}{2} + k_B T \frac{M\omega}{\hbar} x^2 - \frac{k_B T}{2} \log \frac{2\hbar\omega}{k_B T}, \quad (3.839)$$

and the integration leads to the same result (3.835) in only a slightly different way:

$$\begin{aligned} Z_\omega &\xrightarrow{T \rightarrow 0} e^{-\hbar\omega/2k_B T} \sqrt{\frac{2\hbar\omega}{k_B T}} \int_{-\infty}^{\infty} \frac{dx}{l_e(\hbar\beta)} e^{-M\omega x^2/\hbar} \\ &= e^{-\hbar\omega/2k_B T}. \end{aligned} \quad (3.840)$$

There is, however, an important difference of (3.839) with respect to (3.834). The width of a local Boltzmann factor formed from the partition function density (2.332):

$$\tilde{B}(x) \equiv l_e(\hbar\beta) z(x) = e^{-\tilde{V}^{\text{eff cl}}(x)/k_B T} \quad (3.841)$$

is much wider than that of the effective classical Boltzmann factor $B(x_0) = e^{-V^{\text{eff cl}}(x_0)/k_B T}$. Whereas $B(x_0)$ has a finite width for $T \rightarrow 0$, the Boltzmann factor $\tilde{B}(x)$ has a width growing to infinity in this limit. Thus the integral over x in (3.840) converges much more slowly than that over x_0 in (3.835). This is the principal reason for introducing $V^{\text{eff cl}}(x_0)$ as an effective classical potential rather than $\tilde{V}^{\text{eff cl}}(x_0)$.

3.25.5 Harmonic Correlation Function without Zero Mode

By construction, the correlation functions of $\eta(\tau)$ have the desired subtracted form (3.805):

$$\langle \eta(\tau) \eta(\tau') \rangle_\omega = \frac{\hbar}{M} G_{\omega^2, e}^{\text{pr}}(\tau - \tau') = \frac{\hbar}{2M\omega} \frac{\cosh \omega(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\beta\hbar\omega/2)} - \frac{1}{\hbar\beta\omega^2}, \quad (3.842)$$

with the square width as in (3.806):

$$\langle \eta^2(\tau) \rangle_\omega \equiv a_\omega^2 = G_{\omega^2, e}^{\text{P}'}(0) = \frac{1}{2\omega} \coth \frac{\beta \hbar \omega}{2} - \frac{1}{\hbar \beta \omega^2}, \quad (3.843)$$

which decreases with increasing temperature. This can be seen explicitly by adding a current term $-\int d\tau j(\tau)\eta(\tau)$ to the action (3.817) which winds up in the exponent of (3.819), replacing λ/β by $j(\tau) + \lambda/\beta$ and multiplies the exponential in (3.820) by a factor

$$\begin{aligned} & \frac{1}{2M\hbar\beta^2} \left\{ \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \left[\lambda^2 + \lambda\beta j(\tau) + \lambda\beta j(\tau') \right] G_{\omega^2, e}^{\text{P}}(\tau - \tau') \right\} \\ & \times \exp \left\{ \frac{1}{2M\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^{\text{P}}(\tau - \tau') j(\tau') \right\}. \end{aligned} \quad (3.844)$$

In the first exponent, one of the τ -integrals over $G_{\omega^2, e}^{\text{P}}(\tau - \tau')$, say τ' , produces a factor $1/\omega^2$ as in (3.821), so that the first exponent becomes

$$\frac{1}{2M\hbar\beta^2} \left\{ \lambda^2 \frac{\hbar\beta}{\omega^2} + 2 \frac{\lambda\beta}{\omega^2} \int_0^{\hbar\beta} d\tau j(\tau) \right\}. \quad (3.845)$$

If we now perform the integral over λ , the linear term in λ yields, after a quadratic completion, a factor

$$\exp \left\{ -\frac{1}{2M\beta\hbar^2\omega^2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) j(\tau') \right\}. \quad (3.846)$$

Combined with the second exponential in (3.844) this leads to a generating functional for the subtracted correlation functions (3.842):

$$Z_\omega^{x_0}[j] = \frac{\beta\hbar\omega/2}{\sin(\beta\hbar\omega/2)} e^{-\beta M\omega^2 x_0^2/2} \exp \left\{ \frac{1}{2M\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\omega^2, e}^{\text{P}'}(\tau - \tau') j(\tau') \right\}. \quad (3.847)$$

For $j(\tau) \equiv 0$, this reduces to the local Boltzmann factor (3.823).

3.25.6 Perturbation Expansion

We can now apply the perturbation expansion (3.483) to the path integral over $\eta(\tau)$ in Eq. (3.816) for the effective classical Boltzmann factor $B(x_0)$. We take the action

$$\mathcal{A}_e[x] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2 + V(x) \right], \quad (3.848)$$

and rewrite it as

$$\mathcal{A}_e = \hbar\beta V(x_0) + \mathcal{A}_e^{(0)}[\eta] + \mathcal{A}_{\text{int}, e}[x_0; \eta], \quad (3.849)$$

with an unperturbed action

$$\mathcal{A}_e^{(0)}[\eta] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{\eta}^2(\tau) + \frac{M}{2} \Omega^2(x_0) \eta^2(\tau) \right], \quad \Omega^2(x_0) \equiv V''(x_0)/M, \quad (3.850)$$

and an interaction

$$\mathcal{A}_{\text{int,e}}[x_0; \eta] = \int_0^{\hbar\beta} d\tau V^{\text{int}}(x_0; \eta(\tau)), \quad (3.851)$$

containing the subtracted potential

$$V^{\text{int}}(x_0; \eta(\tau)) = V(x_0 + \eta(\tau)) - V(x_0) - V'(x_0)\eta(\tau) - \frac{1}{2}V''(x_0)\eta^2(\tau). \quad (3.852)$$

This has a Taylor expansion starting with the cubic term

$$V^{\text{int}}(x_0; \eta) = \frac{1}{3!}V'''(x_0)\eta^3 + \frac{1}{4!}V^{(4)}(x_0)\eta^4 + \dots \quad (3.853)$$

Since $\eta(\tau)$ has a zero temporal average, the linear term $\int_0^{\hbar\beta} d\tau V'(x_0)\eta(\tau)$ is absent in (3.850). The effective classical Boltzmann factor $B(x_0)$ in (3.816) has then the perturbation expansion [compare (3.483)]

$$B(x_0) = \left(1 - \frac{1}{\hbar} \langle \mathcal{A}_{\text{int,e}} \rangle_{\Omega}^{x_0} + \frac{1}{2!\hbar^2} \langle \mathcal{A}_{\text{int,e}}^2 \rangle_{\Omega}^{x_0} - \frac{1}{3!\hbar^3} \langle \mathcal{A}_{\text{int,e}}^3 \rangle_{\Omega}^{x_0} + \dots \right) B_{\Omega}(x_0). \quad (3.854)$$

The harmonic expectation values are defined with respect to the harmonic path integral

$$B_{\Omega}(x_0) = \int \mathcal{D}\eta \delta(\bar{\eta}) e^{-\mathcal{A}_e^{(0)}[\eta]/\hbar}. \quad (3.855)$$

For an arbitrary functional $F[x]$ one has to calculate

$$\langle F[x] \rangle_{\Omega}^{x_0} = B_{\Omega}^{-1}(x_0) \int \mathcal{D}\eta \delta(\bar{\eta}) F[x] e^{-\mathcal{A}_e^{(0)}[\eta]/\hbar}. \quad (3.856)$$

Some calculations of local expectation values are conveniently done with the explicit Fourier components of the path integral. Recalling (3.809) and expanding the action (3.817) in its Fourier components using (3.807), they are given by the product of integrals

$$\langle F[x] \rangle_{\Omega}^{x_0} = [Z_{\Omega}^{x_0}]^{-1} \prod_{m=1}^{\infty} \left[\int \frac{dx_m^{\text{re}} dx_m^{\text{im}}}{\pi k_B T / M \omega_m^2} \right] e^{-\frac{M}{k_B T} \sum_{m=1}^{\infty} [\omega_m^2 + \Omega^2(x_0)] |x_m|^2} F[x]. \quad (3.857)$$

This implies the correlation functions for the Fourier components

$$\langle x_m x_{m'}^* \rangle_{\Omega}^{x_0} = \delta_{mm'} \frac{k_B T}{M} \frac{1}{\omega_m^2 + \Omega^2(x_0)}. \quad (3.858)$$

From these we can calculate once more the correlation functions of the fluctuations $\eta(\tau)$ as follows:

$$\langle \eta(\tau)\eta(\tau') \rangle_{\Omega}^{x_0} = \left\langle \sum_{m,m' \neq 0}^{\infty} x_m x_{m'}^* e^{-i(\omega_m - \omega_{m'})\tau} \right\rangle_{\Omega}^{x_0} = 2 \frac{1}{M\beta} \sum_{m=1}^{\infty} \frac{1}{\omega_m^2 + \Omega^2(x_0)}. \quad (3.859)$$

Performing the sum gives once more the subtracted correlation function Eq. (3.842), whose generating functional was calculated in (3.847).

The calculation of the harmonic averages in (3.854) leads to a similar loop expansion as for the effective potential in Subsection 3.23.6 using the background field method. The path average x_0 takes over the role of the background X and the non-zero Matsubara frequency part of the paths $\eta(\tau)$ corresponds to the fluctuations. The only difference with respect to the earlier calculations is that the correlation functions of $\eta(\tau)$ contain no zero-frequency contribution. Thus they are obtained from the subtracted Green functions $G_{\Omega^2(x_0),e}^{\text{p}'}$ defined in Eq. (3.805).

All Feynman diagrams in the loop expansion are one-particle irreducible, just as in the loop expansion of the effective potential. The reducible diagrams are absent since there is no linear term in the interaction (3.853). This trivial absence is an advantage with respect to the somewhat involved proof required for the effective action in Subsection 3.23.6. The diagrams in the two expansions are therefore precisely the same and can be read off from Eqs. (3.744) and (3.784). The only difference lies in the replacement $X \rightarrow x_0$ in the analytic expressions for the lines and vertices. In addition, there is the final integral over x_0 to obtain the partition function Z in Eq. (3.811). This is in contrast to the partition function expressed in terms of the effective potential $V^{\text{eff}}(X)$, where only the extremum has to be taken.

3.25.7 Effective Potential and Magnetization Curves

The effective classical potential $V^{\text{eff cl}}(x_0)$ in the Boltzmann factor (3.810) allows us to estimate the *effective potential* defined in Eq. (3.666). It can be derived from the generating functional $Z[j]$ restricted to time-independent external source $j(\tau) \equiv j$, in which case $Z[j]$ reduces to a mere function of j :

$$Z(j) = \int \mathcal{D}x(\tau) \exp \left\{ - \int_0^{\beta} d\tau \left[\frac{1}{2} \dot{x}^2 + V(x(\tau)) \right] + \beta j \bar{x} \right\}, \quad (3.860)$$

where \bar{x} is the path average of $x(\tau)$. The function $Z(j)$ is obtained from the effective classical potential by a simple integral over x_0 :

$$Z(j) = \int_{-\infty}^{\infty} \frac{dx_0}{\sqrt{2\pi\beta}} e^{-\beta[V^{\text{eff cl}}(x_0) - jx_0]}. \quad (3.861)$$

The effective potential $V^{\text{eff}}(X)$ is equal to the Legendre transform of $W(j) = \log Z(j)$:

$$V^{\text{eff}}(X) = -\frac{1}{\beta} W(j) + Xj, \quad (3.862)$$

Figure 3.15 Magnetization curves in double-well potential $V(x) = -x^2/2 + gx^4/4$ with $g = 0.4$, at various inverse temperatures β . The integral over these curves returns the effective potential $V^{\text{eff}}(X)$. The curves arising from the approximate effective potential $W_1(x_0)$ are labeled by β_1 (- - -) and the exact curves (found by solving the Schrödinger equation numerically) by β_{ex} (—). For comparison we have also drawn the classical curves (\cdots) obtained by using the potential $V(x_0)$ in Eqs. (3.864) and (3.861) rather than $W_1(x_0)$. They are labeled by β_V . Our approximation $W_1(x_0)$ is seen to render good magnetization curves for all temperatures above $T = 1/\beta \sim 1/10$. The label β carries several subscripts if the corresponding curves are indistinguishable on the plot. Note that all approximations are monotonous, as they should be (except for the mean field, of course).

where the right-hand side is to be expressed in terms of X using

$$X = X(j) = \frac{1}{\beta} \frac{d}{dj} W(j). \tag{3.863}$$

To picture the effective potential, we calculate the average value of $x(\tau)$ from the integral

$$X = Z(j)^{-1} \int_{-\infty}^{\infty} \frac{dx_0}{\sqrt{2\pi\beta}} x_0 \exp \left\{ -\beta [V^{\text{eff cl}}(x_0) - jx_0] \right\} \tag{3.864}$$

and plot $X = X(j)$. By exchanging the axes we display the inverse $j = j(X)$ which is the slope of the effective potential:

$$j(X) = \frac{dV^{\text{eff}}(X)}{dX}. \tag{3.865}$$

The curves $j(X)$ are shown in Fig. 3.15 for the double-well potential with a coupling strength $g = 0.4$ at various temperatures.

Note that the x_0 -integration makes $j(X)$ necessarily a monotonous function of X . The effective potential is therefore always a convex function of X , no matter what the classical potential looks like. This is in contrast to $j(X)$ before fluctuations are taken into account, the *mean-field approximation* to (3.865) [recall the discussion in Subsection 3.23.1], which is given by

$$j = dV(X)/dX. \quad (3.866)$$

For the double-well potential, this becomes

$$j = -X + gX^3. \quad (3.867)$$

Thus, the mean-field effective potential coincides with the classical potential $V(X)$, which is obviously not convex.

In magnetic systems, j is a constant magnetic field and X its associated magnetization. For this reason, plots of $j(X)$ are referred to as *magnetization curves*.

3.25.8 First-Order Perturbative Result

To first order in the interaction $V^{\text{int}}(x_0; \eta)$, the perturbation expansion (3.854) becomes

$$B(x_0) = \left(1 - \frac{1}{\hbar} \langle \mathcal{A}_{\text{int,e}} \rangle_{\Omega}^{x_0} + \dots \right) B_{\Omega}(x_0), \quad (3.868)$$

and we have to calculate the harmonic expectation value of $\mathcal{A}_{\text{int,e}}$. Let us assume that the interaction potential possesses a Fourier transform

$$V^{\text{int}}(x_0; \eta(\tau)) = \int_{-\infty}^{\infty} \frac{dk}{2\pi} e^{ik(x_0 + \eta(\tau))} \tilde{V}^{\text{int}}(k). \quad (3.869)$$

Then we can write the expectation of (3.851) as

$$\langle \mathcal{A}_{\text{int,e}}[x_0; \eta] \rangle_{\Omega}^{x_0} = \int_0^{\hbar\beta} d\tau \int_{-\infty}^{\infty} \frac{dk}{2\pi} \tilde{V}^{\text{int}}(k) e^{ikx_0} \langle e^{ik\eta(\tau)} \rangle_{\Omega}^{x_0}. \quad (3.870)$$

We now use Wick's rule in the form (3.307) to calculate

$$\langle e^{ik\eta(\tau)} \rangle_{\Omega}^{x_0} = e^{-k^2 \langle \eta^2(\tau) \rangle_{\Omega}^{x_0} / 2}. \quad (3.871)$$

We now use Eq. (3.843) to write this as

$$\langle e^{ik\eta(\tau)} \rangle_{\Omega}^{x_0} = e^{-k^2 a_{\Omega}^2(x_0) / 2}. \quad (3.872)$$

Thus we find for the expectation value (3.870):

$$\langle \mathcal{A}_{\text{int,e}}[x_0; \eta] \rangle_{\Omega}^{x_0} = \int_0^{\hbar\beta} d\tau \int_{-\infty}^{\infty} \frac{dk}{2\pi} \tilde{V}^{\text{int}}(k) e^{ikx_0 - k^2 a_{\Omega}^2(x_0) / 2}. \quad (3.873)$$

Due to the periodic boundary conditions satisfied by the correlation function and the associated invariance under time translations, this result is independent of τ , so that the τ -integral can be performed trivially, yielding simply a factor $\hbar\beta$. We now reinsert the Fourier coefficients of the potential

$$\tilde{V}^{\text{int}}(k) = \int_{-\infty}^{\infty} dx V^{\text{int}}(x_0; \eta) e^{-ik(x_0+\eta)}, \quad (3.874)$$

perform the integral over k via a quadratic completion, and obtain

$$\langle V^{\text{int}}(x(\tau)) \rangle_{\Omega}^{x_0} \equiv V_{a_{\Omega}^2}^{\text{int}}(x_0) = \int_{-\infty}^{\infty} \frac{dx'_0}{\sqrt{2\pi a_{\Omega}^2}} e^{-\eta^2/2a_{\Omega}^2} V^{\text{int}}(x_0; \eta). \quad (3.875)$$

The expectation $\langle V^{\text{int}}(x(\tau)) \rangle_{\Omega}^{x_0} \equiv V_{a_{\Omega}^2}^{\text{int}}(x_0)$ of the potential arises therefore from a convolution integral of the original potential with a Gaussian distribution of square width a_{Ω}^2 . The convolution integral smears the original interaction potential $V_{a_{\Omega}^2}^{\text{int}}(x_0)$ out over a length scale $a_{\Omega}(x_0)$. In this way, the approximation accounts for the quantum-statistical path fluctuations of the particle.

As a result, we can write the first-order Boltzmann factor (3.868) as follows:

$$B(x_0) \approx \frac{\Omega(x_0)\hbar\beta}{2 \sin[\Omega(x_0)\hbar\beta/2]} \exp \left\{ -\beta M \Omega(x_0)^2 x_0^2 / 2 - \beta V_{a_{\Omega}^2}^{\text{int}}(x_0) \right\}. \quad (3.876)$$

Recalling the harmonic effective classical potential (3.834), this may be written as a Boltzmann factor associated with the first-order effective classical potential

$$V^{\text{eff cl}}(x_0) \approx V_{\Omega(x_0)}^{\text{eff cl}}(x_0) + V_{a_{\Omega}^2}^{\text{int}}(x_0). \quad (3.877)$$

Given the power series expansion (3.853) of the interaction potential

$$V^{\text{int}}(x_0; \eta) = \sum_{k=3}^{\infty} \frac{1}{k!} V^{(k)}(x_0) \hbar^k, \quad (3.878)$$

we may use the integral formula

$$\int_{-\infty}^{\infty} \frac{d\eta}{\sqrt{2\pi a^2}} e^{-\eta^2/2a^2} \eta^k = \begin{cases} (k-1)!! a^k \\ 0 \end{cases} \text{ for } k = \begin{cases} \text{even} \\ \text{odd} \end{cases}, \quad (3.879)$$

we find the explicit smeared potential

$$V_{a^2}^{\text{int}}(x_0) = \sum_{k=4,6,\dots}^{\infty} \frac{(k-1)!!}{k!} V^{(k)}(x_0) a^k(x_0). \quad (3.880)$$

3.26 Perturbative Approach to Scattering Amplitude

In Eq. (2.747) we have derived a path integral representation for the scattering amplitude. It involves calculating a path integral of the general form

$$\int d^3 y_a \int d^3 z_a \int \mathcal{D}^3 y \int \mathcal{D}^3 z \exp \left[\frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{M}{2} (\dot{\mathbf{y}}^2 - \dot{\mathbf{z}}^2) \right] F[\mathbf{y}(t) - \mathbf{z}(0)], \quad (3.881)$$

where the paths $\mathbf{y}(t)$ and $\mathbf{z}(t)$ vanish at the final time $t = t_b$ whereas the initial positions are integrated out. In lowest approximation, we may neglect the fluctuations in $\mathbf{y}(t)$ and $\mathbf{z}(0)$ and obtain the eikonal approximation (2.750). In order to calculate higher-order corrections to path integrals of the form (3.881) we find the generating functional of all correlation functions of $\mathbf{y}(t) - \mathbf{z}(0)$.

3.26.1 Generating Functional

For the sake of generality we calculate the harmonic path integral over \mathbf{y} :

$$Z[\mathbf{j}_y] \equiv \int d^3 y_a \int \mathcal{D}^3 y \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \left[\frac{M}{2} (\dot{\mathbf{y}}^2 - \omega^2 \mathbf{y}^2) - \mathbf{j}_y \mathbf{y} \right] \right\}. \quad (3.882)$$

This differs from the amplitude calculated in (3.168) only by an extra Fresnel integral over the initial point and a trivial extension to three dimensions. This yields

$$\begin{aligned} Z[\mathbf{j}_y] &= \int d^3 y_a (\mathbf{y}_b t_b | \mathbf{y}_a t_a)_{\omega}^{\mathbf{j}_y} \\ &= \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt \frac{1}{\sin \omega(t_b - t_a)} [\mathbf{y}_b (\sin [\omega(t - t_a)] + \sin [\omega(t_b - t)]) \mathbf{j}_y] \right\} \\ &\times \exp \left\{ -\frac{i}{\hbar^2} \frac{\hbar}{M} \int_{t_a}^{t_b} dt \int_{t_a}^t dt' \mathbf{j}_y(t) \bar{G}_{\omega^2}(t, t') \mathbf{j}_y(t') \right\}, \end{aligned} \quad (3.883)$$

where $\bar{G}_{\omega^2}(t, t')$ is obtained from the Green function (3.36) with Dirichlet boundary conditions by adding the result of the quadratic completion in the variable $\mathbf{y}_b - \mathbf{y}_a$ preceding the evaluation of the integral over $d^3 y_a$:

$$\bar{G}_{\omega^2}(t, t') = \frac{1}{\omega \sin \omega(t_b - t_a)} \sin \omega(t_b - t_{>}) [\sin \omega(t_{<} - t_a) + \sin \omega(t_b - t_{<})]. \quad (3.884)$$

We need the special case $\omega = 0$ where

$$\bar{G}_{\omega^2}(t, t') = t_b - t_{>}. \quad (3.885)$$

In contrast to $G_{\omega^2}(t, t')$ of (3.36), this Green function vanishes only at the final time. This reflects the fact that the path integral (3.881) is evaluated for paths $\mathbf{y}(t)$ which vanish at the final time $t = t_b$.

A similar generating functional for $\mathbf{z}(t)$ leads to the same result with opposite sign in the exponent. Since the variable $\mathbf{z}(t)$ appears only with time argument zero in (3.881), the relevant generating functional is

$$\begin{aligned} Z[\mathbf{j}] &\equiv \int d^3 y_a \int d^3 z_a \int \mathcal{D}^3 y \int \mathcal{D}^3 z \\ &\times \exp \left(\frac{i}{\hbar} \int_{t_a}^{t_b} dt \left\{ \frac{M}{2} [\dot{\mathbf{y}}^2 - \dot{\mathbf{z}}^2 - \omega^2 (\mathbf{y}^2 - \mathbf{z}^2) - \mathbf{j}_y \mathbf{y} + \mathbf{j}_z \mathbf{z}] \right\} \right), \end{aligned} \quad (3.886)$$

with $\mathbf{y}_b = \mathbf{z}_b = 0$, where we have introduced the subtracted variable

$$\mathbf{y}_z(t) \equiv \mathbf{y}(t) - \mathbf{z}(0), \quad (3.887)$$

for brevity. From the above calculations we can immediately write down the result

$$Z[\mathbf{j}] = \frac{1}{D_\omega} \exp \left\{ -\frac{i}{\hbar^2} \frac{\hbar}{2M} \int_{t_a}^{t_b} dt \int_{t_a}^{t_b} dt' \mathbf{j}(t) \bar{G}'_{\omega^2}(t, t') \mathbf{j}(t') \right\}, \quad (3.888)$$

where D_ω is the functional determinant associated with the Green function (3.884) which is obtained by integrating (3.884) over $t \in (t_b, t_a)$ and over ω^2 :

$$D_\omega = \frac{1}{\cos^2[\omega(t_b - t_a)]} \exp \left[\int_0^{t_b - t_a} \frac{dt}{t} (\cos \omega t - 1) \right], \quad (3.889)$$

and $\bar{G}'_{\omega^2}(t, t')$ is the subtracted Green function (3.884):

$$\bar{G}'_{\omega^2}(t, t') \equiv \bar{G}_{\omega^2}(t, t') - \bar{G}_{\omega^2}(0, 0). \quad (3.890)$$

For $\omega = 0$ where $D_\omega = 1$, this is simply

$$\bar{G}'_0(t, t') \equiv -t_>, \quad (3.891)$$

where $t_>$ denotes the larger of the times t and t' . It is important to realize that thanks to the subtraction in the Green function (3.885) caused by the $\mathbf{z}(0)$ -fluctuations, the limits $t_a \rightarrow -\infty$ and $t_b \rightarrow \infty$ can be taken in (3.888) without any problems.

3.26.2 Application to Scattering Amplitude

We can now apply this result to the path integral (2.747). With the abbreviation (3.887) we write it as

$$\begin{aligned} f_{\mathbf{p}_b, \mathbf{p}_a} &= \frac{p}{2\pi i \hbar} \int d^2b e^{-i\mathbf{q}\mathbf{b}/\hbar} \\ &\times \int \mathcal{D}^3 \mathbf{y}_z \exp \left\{ \frac{i}{\hbar} \int_{-\infty}^{\infty} dt \frac{M}{2} \mathbf{y}_z [\bar{G}'_0(t, t')]^{-1} \mathbf{y}_z \right\} \left[e^{i\chi_{\mathbf{b}, \mathbf{p}}[\mathbf{y}_z]} - 1 \right], \end{aligned} \quad (3.892)$$

where $[\bar{G}'_0(t, t')]^{-1}$ is the functional inverse of the subtracted Green function (3.891), and $\chi_{\mathbf{b}, \mathbf{p}}[\mathbf{y}_z]$ the integral over the interaction potential $V(\mathbf{x})$:

$$\chi_{\mathbf{b}, \mathbf{p}}[\mathbf{y}_z] \equiv -\frac{1}{\hbar} \int_{-\infty}^{\infty} dt V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t + \mathbf{y}_z(t) \right). \quad (3.893)$$

3.26.3 First Correction to Eikonal Approximation

The first correction to the eikonal approximation (2.750) is obtained by expanding (3.893) to first order in $\mathbf{y}_z(t)$. This yields

$$\chi_{\mathbf{b}, \mathbf{p}}[\mathbf{y}] = \chi_{\mathbf{b}, \mathbf{p}}^{\text{ei}} - \frac{1}{\hbar} \int_{-\infty}^{\infty} dt \nabla V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t \right) \mathbf{y}_z(t). \quad (3.894)$$

The additional terms can be considered as an interaction

$$-\frac{1}{\hbar} \int_{-\infty}^{\infty} dt \mathbf{y}_z(t) \mathbf{j}(t), \quad (3.895)$$

with the current

$$\mathbf{j}(t) = \nabla V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t \right). \quad (3.896)$$

Using the generating functional (3.888), this is seen to yield an additional scattering phase

$$\Delta_1 \chi_{\mathbf{b}, \mathbf{p}}^{\text{ei}} = \frac{1}{2M\hbar} \int_{-\infty}^{\infty} dt_1 \int_{-\infty}^{\infty} dt_2 \nabla V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t_1 \right) \nabla V \left(\mathbf{b} + \frac{\mathbf{p}}{M} t_2 \right) t_>. \quad (3.897)$$

To evaluate this we shall always change, as in (2.752), the time variables $t_{1,2}$ to length variables $z_{1,2} \equiv p_{1,2} t/M$ along the direction of \mathbf{p} .

For spherically symmetric potentials $V(r)$ with $r \equiv |\mathbf{x}| = \sqrt{b^2 + z^2}$, we may express the derivatives parallel and orthogonal to the incoming particle momentum \mathbf{p} as follows:

$$\nabla_{\parallel} V = z V'/r, \quad \nabla_{\perp} V = \mathbf{b} V'/r. \quad (3.898)$$

Then (3.897) reduces to

$$\Delta_1 \chi_{\mathbf{b}, \mathbf{p}}^{\text{ei}} = \frac{M^2}{2\hbar p^3} \int_{-\infty}^{\infty} dz_1 \int_{-\infty}^{\infty} dz_2 \frac{V'(r_1)}{r_1} \frac{V'(r_2)}{r_2} (b^2 + z_1 z_2) z_1. \quad (3.899)$$

The part of the integrand before the bracket is obviously symmetric under $z \rightarrow -z$ and under the exchange $z_1 \leftrightarrow z_2$. For this reason we can rewrite

$$\Delta_1 \chi_{\mathbf{b}, \mathbf{p}}^{\text{ei}} = \frac{M^2}{\hbar p^3} \int_{-\infty}^{\infty} dz_1 z_1 \frac{V'(r_1)}{r_1} \int_{-\infty}^{\infty} dz_2 \frac{V'(r_2)}{r_2} (b^2 - z_2^2). \quad (3.900)$$

Now we use the relations (3.898) in the opposite direction as

$$z V'/r = \partial_z V, \quad b V'/r = \partial_b V, \quad (3.901)$$

and performing a partial integration in z_1 to obtain²¹

$$\Delta_1 \chi_{\mathbf{b}, \mathbf{p}}^{\text{ei}} = -\frac{M^2}{\hbar p^3} (1 + b\partial_b) \int_{-\infty}^{\infty} dz V^2 \left(\sqrt{b^2 + z^2} \right). \quad (3.902)$$

Compared to the leading eikonal phase (2.753), this is suppressed by a factor $V(0)M/p^2$.

Note that for the Coulomb potential where $V^2(\sqrt{b^2 + z^2}) \propto 1/(b^2 + z^2)$, the integral is proportional to $1/b$ which is annihilated by the factor $1 + b\partial_b$. Thus there is no first correction to the eikonal approximation (1.506).

3.26.4 Rayleigh-Schrödinger Expansion of Scattering Amplitude

In Section 1.16 we have introduced the scattering amplitude as the limiting matrix element [see (1.516)]

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv \lim_{t_b - t_a \rightarrow \infty} e^{i(E_b - E_a)t_b/\hbar} (\mathbf{p}_b 0 | \mathbf{p}_a t_a) e^{-iE_a t_a/\hbar}. \quad (3.903)$$

A perturbation expansion for these quantities can be found via a Fourier transformation of the expansion (3.477). We only have to set the oscillator frequency of the harmonic part of the action equal to zero, since the particles in a scattering process are free far away from the scattering center. Since scattering takes usually place in three dimensions, all formulas will be written down in such a space.

²¹This agrees with results from Schrödinger theory by S.J. Wallace, *Ann. Phys.* 78, 190 (1973); S. Sarkar, *Phys. Rev. D* 21, 3437 (1980). It differs from R. Rosenfelder's result (see Footnote 38 on p. 193) who derives a prefactor $p \cos(\theta/2)$ instead of the incoming momentum p .

We shall thus consider the perturbation expansion of the amplitude

$$(\mathbf{p}_b 0 | \mathbf{p}_a t_a) = \int d^3 x_b d^3 x_a e^{-i\mathbf{p}_b \mathbf{x}_b} (\mathbf{x}_b 0 | \mathbf{x}_a t_a) e^{i\mathbf{p}_a \mathbf{x}_a}, \quad (3.904)$$

where $(\mathbf{x}_b 0 | \mathbf{x}_a t_a)$ is expanded as in (3.477). The immediate result looks as in the expansion (3.500), if we replace the external oscillator wave functions $\psi_n(x_b)$ and $\psi_a(x_b)$ by free-particle plane waves $e^{-i\mathbf{p}_b \mathbf{x}_b}$ and $e^{i\mathbf{p}_a \mathbf{x}_a}$:

$$\begin{aligned} (\mathbf{p}_b 0 | \mathbf{p}_a t_a) &= (\mathbf{p}_b 0 | \mathbf{p}_a t_a)_0 \\ &+ \frac{i}{\hbar} \langle \mathbf{p}_b | \mathcal{A}_{\text{int}} | \mathbf{p}_a \rangle_0 - \frac{1}{2! \hbar^2} \langle \mathbf{p}_b | \mathcal{A}_{\text{int}}^2 | \mathbf{p}_a \rangle_0 - \frac{i}{3! \hbar^3} \langle \mathbf{p}_b | \mathcal{A}_{\text{int}}^3 | \mathbf{p}_a \rangle_0 + \dots \end{aligned} \quad (3.905)$$

Here

$$(\mathbf{p}_b 0 | \mathbf{p}_a t_a)_0 = (2\pi\hbar)^3 \delta^{(3)}(\mathbf{p}_b - \mathbf{p}_a) e^{i\mathbf{p}_b^2 t_a / 2M\hbar} \quad (3.906)$$

is the free-particle time evolution amplitude in momentum space [recall (2.73)] and the matrix elements are defined by

$$\langle \mathbf{p}_b | \dots | \mathbf{p}_a \rangle_0 \equiv \int d^3 x_b d^3 x_a e^{-i\mathbf{p}_b \mathbf{x}_b} \left(\int \mathcal{D}^3 x \dots e^{iA_0/\hbar} \right) e^{i\mathbf{p}_a \mathbf{x}_a}. \quad (3.907)$$

In contrast to (3.500) we have not divided out the free-particle amplitude (3.906) in this definition since it is too singular. Let us calculate the successive terms in the expansion (3.905). First

$$\begin{aligned} \langle \mathbf{p}_b | \mathcal{A}_{\text{int}} | \mathbf{p}_a \rangle_0 &= - \int_{t_a}^0 dt_1 \int d^3 x_b d^3 x_a d^3 x_1 e^{-i\mathbf{p}_b \mathbf{x}_b} (\mathbf{x}_b 0 | \mathbf{x}_1 t_1)_0 \\ &\quad \times V(\mathbf{x}_1) (\mathbf{x}_1 t_1 | \mathbf{x}_a t_a)_0 e^{i\mathbf{p}_a \mathbf{x}_a}. \end{aligned} \quad (3.908)$$

Since

$$\begin{aligned} \int d^3 x_b e^{-i\mathbf{p}_b \mathbf{x}_b} (\mathbf{x}_b t_b | \mathbf{x}_1 t_1)_0 &= e^{-i\mathbf{p}_b \mathbf{x}_1} e^{-i\mathbf{p}_b^2 (t_b - t_1) / 2M\hbar}, \\ \int d^3 x_a (\mathbf{x}_1 t_1 | \mathbf{x}_a t_a)_0 e^{-i\mathbf{p}_b \mathbf{x}_b} &= e^{-i\mathbf{p}_a \mathbf{x}_1} e^{i\mathbf{p}_a^2 (t_1 - t_a) / 2M\hbar}, \end{aligned} \quad (3.909)$$

this becomes

$$\langle \mathbf{p}_b | \mathcal{A}_{\text{int}} | \mathbf{p}_a \rangle_0 = - \int_{t_a}^0 dt_1 e^{i(\mathbf{p}_b^2 - \mathbf{p}_a^2) t_1 / 2M\hbar} V_{\mathbf{p}_b \mathbf{p}_a} e^{i\mathbf{p}_a^2 t_a / 2M\hbar}, \quad (3.910)$$

where

$$V_{\mathbf{p}_b \mathbf{p}_a} \equiv \langle \mathbf{p}_b | \hat{V} | \mathbf{p}_a \rangle = \int d^3 x e^{i(\mathbf{p}_b - \mathbf{p}_a) \mathbf{x} / \hbar} V(\mathbf{x}) = \tilde{V}(\mathbf{p}_b - \mathbf{p}_a) \quad (3.911)$$

[recall (1.494)]. Inserting a damping factor $e^{\eta t_1}$ into the time integral, and replacing $\mathbf{p}^2/2M$ by the corresponding energy E , we obtain

$$\frac{i}{\hbar} \langle \mathbf{p}_b | \mathcal{A}_{\text{int}} | \mathbf{p}_a \rangle_0 = - \frac{1}{E_b - E_a - i\eta} V_{\mathbf{p}_b \mathbf{p}_a} e^{iE_a t_a}. \quad (3.912)$$

Inserting this together with (3.906) into the expansion (3.905), we find for the scattering amplitude (3.903) the first-order approximation

$$\langle \mathbf{p}_b | \hat{S} | \mathbf{p}_a \rangle \equiv \lim_{t_b - t_a \rightarrow \infty} e^{i(E_b - E_a)t_b/\hbar} \left[(2\pi\hbar)^3 \delta^{(3)}(\mathbf{p}_b - \mathbf{p}_a) - \frac{1}{E_b - E_a - i\eta} V_{\mathbf{p}_b \mathbf{p}_a} \right] \quad (3.913)$$

corresponding precisely to the first-order approximation of the operator expression (1.519), the Born approximation.

Continuing the evaluation of the expansion (3.905) we find that $V_{\mathbf{p}_b \mathbf{p}_a}$ in (3.913) is replaced by the T -matrix [recall (1.477)]

$$\begin{aligned} T_{\mathbf{p}_b \mathbf{p}_a} &= V_{\mathbf{p}_b \mathbf{p}_a} - \int \frac{d^3 p_c}{(2\pi\hbar)^3} V_{\mathbf{p}_b \mathbf{p}_c} \frac{1}{E_c - E_a - i\eta} V_{\mathbf{p}_c \mathbf{p}_a} \\ &+ \int \frac{d^3 p_c}{(2\pi\hbar)^3} \int \frac{d^3 p_d}{(2\pi\hbar)^3} V_{\mathbf{p}_b \mathbf{p}_c} \frac{1}{E_c - E_a - i\eta} V_{\mathbf{p}_c \mathbf{p}_d} \frac{1}{E_d - E_a - i\eta} V_{\mathbf{p}_d \mathbf{p}_a} + \dots \end{aligned} \quad (3.914)$$

This amounts to an integral equation

$$T_{\mathbf{p}_b \mathbf{p}_a} = V_{\mathbf{p}_b \mathbf{p}_a} - \int \frac{d^3 p_c}{(2\pi\hbar)^3} V_{\mathbf{p}_b \mathbf{p}_c} \frac{1}{E_c - E_a - i\eta} T_{\mathbf{p}_c \mathbf{p}_a}, \quad (3.915)$$

which is recognized as the Lippmann-Schwinger equation (1.525) for the T -matrix.

3.27 Functional Determinants from Green Functions

In Subsection 3.2.1 we have seen that there exists a simple method, due to Wronski, for constructing Green functions of the differential equation (3.27),

$$\mathcal{O}(t)G_{\omega^2}(t, t') \equiv [-\partial_t^2 - \Omega^2(t)]G_{\omega^2}(t, t') = \delta(t - t'), \quad (3.916)$$

with Dirichlet boundary conditions. That method did not require any knowledge of the spectrum and the eigenstates of the differential operator $\mathcal{O}(t)$, except for the condition that zero-modes are absent. The question arises whether this method can be used to find also functional determinants.²² The answer is positive, and we shall now demonstrate that Gelfand and Yaglom's initial-value problem (2.213), (2.214), (2.215) with the Wronski construction (2.225) for its solution represents the most concise formula for the functional determinant of the operator $\mathcal{O}(t)$. Starting point is the observation that a functional determinant of an operator \mathcal{O} can be written as

$$\text{Det } \mathcal{O} = e^{\text{Tr } \log \mathcal{O}}, \quad (3.917)$$

and that a Green function of a harmonic oscillator with an arbitrary time-dependent frequency has the integral

$$\begin{aligned} \text{Tr} \left\{ \int_0^1 dg \Omega^2(t) [-\partial_t^2 - g\Omega^2(t)]^{-1} \delta(t - t') \right\} &= -\text{Tr} \{ \log [-\partial_t^2 - \Omega^2(t)] \delta(t - t') \} \\ &+ \text{Tr} \{ \log [-\partial_t^2] \delta(t - t') \}. \end{aligned} \quad (3.918)$$

²²See the reference in Footnote 6 on p. 247.

If we therefore introduce a strength parameter $g \in [0, 1]$ and an auxiliary Green function $G_g(t, t')$ satisfying the differential equation

$$\mathcal{O}_g(t)G_g(t, t') \equiv [-\partial_t^2 - g\Omega^2(t)]G_g(t, t') = \delta(t - t'), \quad (3.919)$$

we can express the ratio of functional determinants $\text{Det } \mathcal{O}_1/\text{Det } \mathcal{O}_0$ as

$$\text{Det } (\mathcal{O}_0^{-1}\mathcal{O}_1) = e^{-\int_0^1 dg \text{Tr } [\Omega^2(t)G_g(t, t')]} \quad (3.920)$$

Knowing of the existence of Gelfand-Yaglom's elegant method for calculating functional determinants in Section 2.4, we now try to relate the right-hand side in (3.920) to the solution of the Gelfand-Yaglom's equations (2.215), (2.213), and (2.214):

$$\mathcal{O}_g(t)D_g(t) = 0; \quad D_g(t_a) = 0, \quad \dot{D}_g(t_a) = 1. \quad (3.921)$$

By differentiating these equations with respect to the parameter g , we obtain for the g -derivative $D'_g(t) \equiv \partial_g D_g(t)$ the inhomogeneous initial-value problem

$$\mathcal{O}_g(t)D'_g(t) = \Omega^2(t)D_g(t); \quad D'_g(t_a) = 0, \quad \dot{D}'_g(t_a) = 0. \quad (3.922)$$

The unique solution of equations (3.921) can be expressed as in Eq. (2.221) in terms of an arbitrary set of solutions $\eta_g(t)$ and $\xi_g(t)$ as follows

$$D_g(t) = \frac{\xi_g(t_a)\eta_g(t) - \xi_g(t)\eta_g(t_a)}{W_g} = \Delta_g(t, t_a), \quad (3.923)$$

where W_g is the constant Wronski determinant

$$W_g = \xi_g(t)\dot{\eta}_g(t) - \eta_g(t)\dot{\xi}_g(t). \quad (3.924)$$

We may also write

$$D_g(t_b) = \frac{\text{Det } \Lambda_g}{W_g} = \Delta_g(t_b, t_a), \quad (3.925)$$

where Λ_g is the constant 2×2 -matrix

$$\Lambda_g = \begin{pmatrix} \xi_g(t_a) & \eta_g(t_a) \\ \xi_g(t_b) & \eta_g(t_b) \end{pmatrix}. \quad (3.926)$$

With the help of the solution $\Delta_g(t, t')$ of the homogenous initial-value problem (3.921) we can easily construct a solution of the inhomogeneous initial-value problem (3.922) by superposition:

$$D'_g(t) = \int_{t_a}^t dt' \Omega^2(t') \Delta_g(t, t') \Delta_g(t', t_a). \quad (3.927)$$

Comparison with (3.59) shows that at the final point $t = t_b$

$$D'_g(t_b) = \Delta_g(t_b, t_a) \int_{t_a}^{t_b} dt' \Omega^2(t') G_g(t', t'). \quad (3.928)$$

Together with (3.925), this implies the following equation for the integral over the Green function which solves (3.916) with Dirichlet's boundary conditions:

$$\text{Tr} [\Omega^2(t)G_g(t, t')] = -\partial_g \log \left(\frac{\det \Lambda_g}{W_g} \right) = -\partial_g \log D_g(t_b). \quad (3.929)$$

Inserting this into (3.918), we find for the ratio of functional determinants the simple formula

$$\text{Det} (\mathcal{O}_0^{-1} \mathcal{O}_g) = C(t_b, t_a) D_g(t_b). \quad (3.930)$$

The constant of g -integration, which still depends in general on initial and final times, is fixed by applying (3.930) to the trivial case $g = 0$, where $\mathcal{O}_0 = -\partial_t^2$ and the solution to the initial-value problem (3.921) is

$$D_0(t) = t - t_a. \quad (3.931)$$

At $g = 0$, the left-hand side of (3.930) is unity, determining $C(t_b, t_a) = (t_b - t_a)^{-1}$ and the final result for $g = 1$:

$$\text{Det} (\mathcal{O}_0^{-1} \mathcal{O}_1) = \frac{\det \Lambda_1}{W_1} \bigg/ \frac{\text{Det} \Lambda_0}{W_0} = \frac{D_1(t_b)}{t_b - t_a}, \quad (3.932)$$

in agreement with the result of Section 2.7.

The same method permits us to find the Green function $G_{\omega^2}(\tau, \tau')$ governing quantum statistical harmonic fluctuations which satisfies the differential equation

$$\mathcal{O}_g(\tau) G_g^{\text{p,a}}(\tau, \tau') \equiv [\partial_\tau^2 - g\Omega^2(\tau)] G_g^{\text{p,a}}(\tau, \tau') = \delta^{\text{p,a}}(\tau - \tau'), \quad (3.933)$$

with periodic and antiperiodic boundary conditions, frequency $\Omega(\tau)$, and δ -function. The imaginary-time analog of (3.918) for the ratio of functional determinants reads

$$\text{Det} (\mathcal{O}_0^{-1} \mathcal{O}_1) = e^{-\int_0^1 dg \text{Tr} [\Omega^2(\tau) G_g(\tau, \tau')]} \quad (3.934)$$

The boundary conditions satisfied by the Green function $G_g^{\text{p,a}}(\tau, \tau')$ are

$$\begin{aligned} G_g^{\text{p,a}}(\tau_b, \tau') &= \pm G_g^{\text{p,a}}(\tau_a, \tau'), \\ \dot{G}_g^{\text{p,a}}(\tau_b, \tau') &= \pm \dot{G}_g^{\text{p,a}}(\tau_a, \tau'). \end{aligned} \quad (3.935)$$

According to Eq. (3.166), the Green functions are given by

$$G_g^{\text{p,a}}(\tau, \tau') = G_g(\tau, \tau') \mp \frac{[\Delta_g(\tau, \tau_a) \pm \Delta_g(\tau_b, \tau)][\Delta_g(\tau', \tau_a) \pm \Delta_g(\tau_b, \tau')]}{\bar{\Delta}_g^{\text{p,a}}(\tau_a, \tau_b) \cdot \Delta_g(\tau_a, \tau_b)}, \quad (3.936)$$

where [compare (3.49)]

$$\Delta(\tau, \tau') = \frac{1}{W} [\xi(\tau)\eta(\tau') - \xi(\tau')\eta(\tau)], \quad (3.937)$$

with the Wronski determinant $W = \xi(\tau)\dot{\eta}(\tau) - \dot{\xi}(\tau)\eta(\tau)$, and [compare (3.165)]

$$\bar{\Delta}_g^{\text{p,a}}(\tau_a, \tau_b) = 2 \pm \partial_\tau \Delta_g(\tau_a, \tau_b) \pm \partial_\tau \Delta_g(\tau_b, \tau_a). \quad (3.938)$$

The solution is unique provided that

$$\det \bar{\Lambda}_g^{\text{p,a}} = W_g \bar{\Delta}_g^{\text{p,a}}(\tau_a, \tau_b) \neq 0. \quad (3.939)$$

The right-hand side is well-defined unless the operator $\mathcal{O}_g(t)$ has a zero-mode with $\eta_g(t_b) = \pm \eta_g(t_a)$, $\dot{\eta}_g(t_b) = \pm \dot{\eta}_g(t_a)$, which would make the determinant of the 2×2 -matrix $\bar{\Lambda}_g^{\text{p,a}}$ vanish.

We are now in a position to rederive the functional determinant of the operator $\mathcal{O}(\tau) = \partial_\tau^2 - \Omega^2(\tau)$ with periodic or antiperiodic boundary conditions more elegantly than in Section 2.11. For this we formulate again a homogeneous initial-value problem, but with boundary conditions dual to Gelfand and Yaglom's in Eq. (3.921):

$$\mathcal{O}_g(\tau)\bar{D}_g(\tau) = 0; \quad \bar{D}_g(\tau_a) = 1, \quad \dot{\bar{D}}_g(\tau_a) = 0. \quad (3.940)$$

In terms of the previous arbitrary set $\eta_g(t)$ and $\xi_g(t)$ of solutions of the homogeneous differential equation, the unique solution of (3.940) reads

$$\bar{D}_g(\tau) = \frac{\xi_g(\tau)\dot{\eta}_g(\tau_a) - \dot{\xi}_g(\tau_a)\eta_g(\tau)}{W_g}. \quad (3.941)$$

This can be combined with the time derivative of (3.923) at $\tau = \tau_b$ to yield

$$\dot{D}_g(\tau_b) + \bar{D}_g(\tau_b) = \pm[2 - \bar{\Delta}_g^{\text{p,a}}(\tau_a, \tau_b)]. \quad (3.942)$$

By differentiating Eqs. (3.940) with respect to g , we obtain the following inhomogeneous initial-value problem for $\bar{D}'_g(\tau) = \partial_g \bar{D}_g(\tau)$:

$$\mathcal{O}_g(\tau)\bar{D}'_g(\tau) = \Omega^2(\tau)\bar{D}'_g(\tau); \quad \bar{D}'_g(\tau_a) = 1, \quad \dot{\bar{D}}'_g(\tau_a) = 0, \quad (3.943)$$

whose general solution reads by analogy with (3.927)

$$\bar{D}'_g(\tau) = - \int_{\tau_a}^{\tau} d\tau' \Omega^2(\tau') \Delta_g(\tau, \tau') \dot{\Delta}_g(\tau_a, \tau'), \quad (3.944)$$

where the dot on $\dot{\Delta}_g(\tau_a, \tau')$ acts on the first imaginary-time argument. With the help of identities (3.942) and (3.943), the combination $\dot{D}'(\tau) + \bar{D}'_g(\tau)$ at $\tau = \tau_b$ can now be expressed in terms of the periodic and antiperiodic Green functions (3.166), by analogy with (3.928),

$$\dot{D}'_g(\tau_b) + \bar{D}'_g(\tau_b) = \pm \bar{\Delta}_g^{\text{p,a}}(\tau_a, \tau_b) \int_{\tau_a}^{\tau_b} d\tau \Omega^2(\tau) G_g^{\text{p,a}}(\tau, \tau). \quad (3.945)$$

Together with (3.942), this gives for the temporal integral on the right-hand side of (3.920) the simple expression analogous to (3.929)

$$\begin{aligned} \text{Tr} [\Omega^2(\tau)G_g^{\text{p,a}}(\tau, \tau')] &= -\partial_g \log \left(\frac{\det \bar{\Lambda}_g^{\text{p,a}}}{Wg} \right) \\ &= -\partial_g \log [2 \mp \dot{D}_g(\tau_b) \mp \bar{D}_g(\tau_b)], \end{aligned} \tag{3.946}$$

so that we obtain the ratio of functional determinants with periodic and antiperiodic boundary conditions

$$\text{Det} (\tilde{\mathcal{O}}^{-1}\mathcal{O}_g) = C(t_b, t_a) [2 \mp \dot{D}_g(\tau_b) \mp \bar{D}_g(\tau_b)], \tag{3.947}$$

where $\tilde{\mathcal{O}} = \mathcal{O}_0 - \omega^2 = \partial_\tau^2 - \omega^2$. The constant of integration $C(t_b, t_a)$ is fixed in the way described after Eq. (3.918). We go to $g = 1$ and set $\Omega^2(\tau) \equiv \omega^2$. For the operator $\mathcal{O}_1^\omega \equiv -\partial_\tau^2 - \omega^2$, we can easily solve the Gelfand-Yaglom initial-value problem (3.921) as well as the dual one (3.940) by

$$D_1^\omega(\tau) = \frac{1}{\omega} \sin \omega(\tau - \tau_a), \quad \bar{D}_1^\omega(\tau) = \cos \omega(\tau - \tau_a), \tag{3.948}$$

so that (3.947) determines $C(t_b, t_a)$ by

$$1 = C(t_b, t_a) \begin{cases} 4 \sin^2[\omega(\tau_b - \tau_a)/2] & \text{periodic case,} \\ 4 \cos^2[\omega(\tau_b - \tau_a)/2] & \text{antiperiodic case.} \end{cases} \tag{3.949}$$

Hence we find the final results for periodic boundary conditions

$$\text{Det} (\tilde{\mathcal{O}}^{-1}\mathcal{O}_1) = \frac{\det \bar{\Lambda}_1^{\text{p}}}{W_1} \bigg/ \frac{\text{Det} \bar{\Lambda}_1^{\omega \text{p}}}{W_1^\omega} = \frac{2 - \dot{D}_1(\tau_b) - \bar{D}_1(\tau_b)}{4 \sin^2[\omega(\tau_b - \tau_a)/2]}, \tag{3.950}$$

and for antiperiodic boundary conditions

$$\text{Det} (\tilde{\mathcal{O}}^{-1}\mathcal{O}_1) = \frac{\det \bar{\Lambda}_1^{\text{a}}}{W_1} \bigg/ \frac{\text{Det} \bar{\Lambda}_1^{\omega \text{a}}}{W_1^\omega} = \frac{2 + \dot{D}_1(\tau_b) + \bar{D}_1(\tau_b)}{4 \cos^2[\omega(\tau_b - \tau_a)/2]}. \tag{3.951}$$

The intermediate expressions in (3.932), (3.950), and (3.951) show that the ratios of functional determinants are ordinary determinants of two arbitrary independent solutions ξ and η of the homogeneous differential equation $\mathcal{O}_1(t)y(t) = 0$ or $\mathcal{O}_1(\tau)y(\tau) = 0$. As such, the results are manifestly invariant under arbitrary linear transformations of these functions $(\xi, \eta) \rightarrow (\xi', \eta')$.

It is useful to express the above formulas for the ratio of functional determinants (3.932), (3.950), and (3.951) in yet another form. We rewrite the two independent solutions of the homogenous differential equation $[-\partial_t^2 - \Omega^2(t)]y(t) = 0$ as follows

$$\xi(t) = q(t) \cos \phi(t), \quad \eta(t) = q(t) \sin \phi(t). \tag{3.952}$$

The two functions $q(t)$ and $\phi(t)$ parametrizing $\xi(t)$ and $\eta(t)$ satisfy the constraint

$$\dot{\phi}(t)q^2(t) = W, \quad (3.953)$$

where W is the constant Wronski determinant. The function $q(t)$ is a soliton of the Ermankov-Pinney equation²³

$$\ddot{q} + \Omega^2(t)q - W^2q^{-3} = 0. \quad (3.954)$$

For Dirichlet boundary conditions we insert (3.952) into (3.932), and obtain the ratio of fluctuation determinants in the form

$$\text{Det}(\mathcal{O}_0^{-1}\mathcal{O}_1) = \frac{1}{W} \frac{q(t_a)q(t_b) \sin[\phi(t_b) - \phi(t_a)]}{t_b - t_a}. \quad (3.955)$$

For periodic or antiperiodic boundary conditions with a corresponding frequency $\Omega(t)$, the functions $q(t)$ and $\phi(t)$ in Eq. (3.952) have the same periodicity. The initial value $\phi(t_a)$ may always be assumed to vanish, since otherwise $\xi(t)$ and $\eta(t)$ could be combined linearly to that effect. Substituting (3.952) into (3.950) and (3.951), the function $q(t)$ drops out, and we obtain the ratios of functional determinants for periodic boundary conditions

$$\text{Det}(\tilde{\mathcal{O}}^{-1}\mathcal{O}_1) = 4 \sin^2 \frac{\phi(t_b)}{2} / 4 \sin^2 \frac{\omega(t_b - t_a)}{2}, \quad (3.956)$$

and for antiperiodic boundary conditions

$$\text{Det}(\tilde{\mathcal{O}}^{-1}\mathcal{O}_1) = 4 \cos^2 \frac{\phi(t_b)}{2} / 4 \cos^2 \frac{\omega(t_b - t_a)}{2}. \quad (3.957)$$

For a harmonic oscillator with $\Omega(t) \equiv \omega$, Eq. (3.954) is solved by

$$q(t) \equiv \sqrt{\frac{W}{\omega}}, \quad (3.958)$$

and Eq. (3.953) yields

$$\phi(t) = \omega(t - t_a). \quad (3.959)$$

Inserted into (3.955), (3.956), and (3.957) we reproduce the known results:

$$\text{Det}(\mathcal{O}_0^{-1}\mathcal{O}_1) = \frac{\sin \omega(t_b - t_a)}{\omega(t_b - t_a)}, \quad \text{Det}(\tilde{\mathcal{O}}^{-1}\mathcal{O}_1) = 1.$$

²³For more details see J. Rezende, *J. Math. Phys.* 25, 3264 (1984).

Appendix 3A Matrix Elements for General Potential

The matrix elements $\langle n|\hat{V}|m\rangle$ can be calculated for an arbitrary potential $\hat{V} = V(\hat{x})$ as follows: We represent $V(\hat{x})$ by a Fourier integral as a superposition of exponentials

$$V(\hat{x}) = \int_{-i\infty}^{i\infty} \frac{dk}{2\pi i} V(k) \exp(k\hat{x}), \quad (3A.1)$$

and express $\exp(k\hat{x})$ in terms of creation and annihilation operators as $\exp(k\hat{x}) = \exp[k(\hat{a} + \hat{a}^\dagger)/\sqrt{2}]$, set $k \equiv \sqrt{2}\epsilon$, and write down the obvious equation

$$\langle n|e^{\epsilon\sqrt{2}\hat{x}}|m\rangle = \frac{1}{\sqrt{n!m!}} \frac{\partial^n}{\partial\alpha^n} \frac{\partial^m}{\partial\beta^m} \langle 0|e^{\alpha\hat{a}} e^{\epsilon(\hat{a}+\hat{a}^\dagger)} e^{\beta\hat{a}^\dagger}|0\rangle \Big|_{\alpha=\beta=0}. \quad (3A.2)$$

We now make use of the Baker-Campbell-Hausdorff Formula (2A.1) with (2A.6), and rewrite

$$e^{\hat{A}} e^{\hat{B}} = e^{\hat{A}+\hat{B} + \frac{1}{2}[\hat{A},\hat{B}] + \frac{1}{12}([\hat{A},[\hat{A},\hat{B}]] + [\hat{B},[\hat{B},\hat{A}]] + \dots)}. \quad (3A.3)$$

Identifying \hat{A} and \hat{B} with \hat{a} and \hat{a}^\dagger , the property $[\hat{a}, \hat{a}^\dagger] = 1$ makes this relation very simple:

$$e^{\epsilon(\hat{a}+\hat{a}^\dagger)} = e^{\epsilon\hat{a}} e^{\epsilon\hat{a}^\dagger} e^{-\epsilon^2/2}, \quad (3A.4)$$

and the matrix elements (3A.2) become

$$\langle 0|e^{\alpha\hat{a}} e^{\epsilon(\hat{a}+\hat{a}^\dagger)} e^{\beta\hat{a}^\dagger}|0\rangle = \langle 0|e^{(\alpha+\epsilon)\hat{a}} e^{(\beta+\epsilon)\hat{a}^\dagger}|0\rangle e^{-\epsilon^2/2}. \quad (3A.5)$$

The bra and ket states on the right-hand side are now eigenstates of the annihilation operator \hat{a} with eigenvalues $\alpha + \epsilon$ and $\beta + \epsilon$, respectively. Such states are known as *coherent states*.²⁴ Using once more (3A.3), we obtain

$$\langle 0|e^{(\alpha+\epsilon)\hat{a}} e^{(\beta+\epsilon)\hat{a}^\dagger}|0\rangle = e^{(\epsilon+\alpha)(\epsilon+\beta)}, \quad (3A.6)$$

and (3A.2) becomes simply

$$\langle n|e^{\epsilon\sqrt{2}\hat{x}}|m\rangle = \frac{1}{\sqrt{n!m!}} \frac{\partial^n}{\partial\alpha^n} \frac{\partial^m}{\partial\beta^m} e^{(\alpha+\epsilon)(\beta+\epsilon)} e^{-\epsilon^2/2} \Big|_{\alpha=\beta=0}. \quad (3A.7)$$

We now calculate the derivatives

$$\frac{\partial^n}{\partial\alpha^n} \frac{\partial^m}{\partial\beta^m} e^{(\epsilon+\alpha)(\epsilon+\beta)} \Big|_{\alpha=\beta=0} = \frac{\partial^n}{\partial\alpha^n} (\epsilon + \alpha)^m e^{\epsilon(\epsilon+\alpha)} \Big|_{\alpha=0}. \quad (3A.8)$$

Using the chain rule of differentiation for products $f(x) = g(x)h(x)$:

$$f^{(n)}(x) = \sum_{l=0}^n \binom{n}{l} g^{(l)}(x) h^{(n-l)}(x), \quad (3A.9)$$

the right-hand side becomes

$$\begin{aligned} \frac{\partial^n}{\partial\alpha^n} (\epsilon + \alpha)^m e^{\epsilon(\epsilon+\alpha)} \Big|_{\alpha=0} &= \sum_{l=0}^n \binom{n}{l} \frac{\partial^l}{\partial\alpha^l} (\epsilon + \alpha)^m \frac{\partial^{n-l}}{\partial\alpha^{n-l}} e^{\epsilon(\epsilon+\alpha)} \Big|_{\alpha=0} \\ &= \sum_{l=0}^n \binom{n}{l} m(m-1)\cdots(m-l+1) \epsilon^{n+m-2l} e^{\epsilon^2}. \end{aligned} \quad (3A.10)$$

²⁴The use of coherent states was advanced by R.J. Glauber, Phys. Rev. **131**, 2766 (1963).

Hence we find

$$\langle n|e^{\epsilon\sqrt{2}\hat{x}}|m\rangle = \frac{1}{\sqrt{n!m!}} \sum_{l=0}^n \binom{n}{l} \binom{m}{l} l! e^{n+m-2l} e^{\epsilon^2/2}. \quad (3A.11)$$

From this we obtain the matrix elements of single powers \hat{x}^p by forming, with the help of (3A.9) and $(\partial^q/\partial\epsilon^q)e^{\epsilon^2/2}|_{\epsilon=0} = q!!$, the derivatives

$$\left. \frac{\partial^p}{\partial\epsilon^p} \epsilon^{n+m-2l} e^{\epsilon^2/2} \right|_{\epsilon=0} = \binom{p}{n+m-2l} [2l - (n+m-p)]!! = \frac{p!}{2^{l-(n+m-p)/2} [l-p - (n+m-p)/2]!}. \quad (3A.12)$$

The result is

$$\langle n|\hat{x}^p|m\rangle = \frac{1}{\sqrt{n!m!}} \sum_{l=(n+m-p)/2}^{\min(n,m)} \binom{n}{l} \binom{m}{l} l! \frac{p!}{2^{l+p-(n+m)/2} [l - (n+m-p)/2]!}. \quad (3A.13)$$

For the special case of a pure fourth-order interaction, this becomes

$$\begin{aligned} \langle n|\hat{x}^4|n-4\rangle &= \frac{1}{4}\sqrt{n-3}\sqrt{n-2}\sqrt{n-1}\sqrt{n}, \\ \langle n|\hat{x}^4|n-2\rangle &= \frac{1}{4}(4n-2)\sqrt{n-1}\sqrt{n}, \\ \langle n|\hat{x}^4|n\rangle &= \frac{1}{4}(6n^2+6n+3), \\ \langle n|\hat{x}^4|n+2\rangle &= \frac{1}{4}(4n+6)\sqrt{n+1}\sqrt{n+2}, \\ \langle n|\hat{x}^4|n+4\rangle &= \frac{1}{4}\sqrt{n+1}\sqrt{n+2}\sqrt{n+3}\sqrt{n+4}. \end{aligned} \quad (3A.14)$$

For a general potential (3A.1) we find

$$\langle n|V(\hat{x})|m\rangle = \frac{1}{\sqrt{n!m!}} \sum_{l=0}^n \binom{n}{l} \binom{m}{l} l! \frac{1}{2^{l-(n+m)/2}} \int_{-i\infty}^{i\infty} \frac{dk}{2\pi i} V(k) k^{n+m-2l} e^{k^2/4}. \quad (3A.15)$$

Appendix 3B Energy Shifts for $gx^4/4$ -Interaction

For the specific polynomial interaction $V(x) = gx^4/4$, the shift of the energy $E^{(n)}$ to any desired order is calculated most simply as follows. Consider the expectations of powers $\hat{x}^4(z_1)\hat{x}^4(z_2)\cdots\hat{x}^4(z_n)$ of the operator $\hat{x}(z) = (\hat{a}^\dagger z + \hat{a}z^{-1})$ between the excited oscillator states $\langle n|$ and $|n\rangle$. Here \hat{a} and \hat{a}^\dagger are the usual creation and annihilation operators of the harmonic oscillator, and $|n\rangle = (a^\dagger)^n|0\rangle/\sqrt{n!}$. To evaluate these expectations, we make repeated use of the commutation rules $[\hat{a}, \hat{a}^\dagger] = 1$ and of the ground state property $\hat{a}|0\rangle = 0$. For $n = 0$ this gives

$$\begin{aligned} \langle x^4(z) \rangle_\omega &= 3, \\ \langle x^4(z_1)x^4(z_2) \rangle_\omega &= 72z_1^{-2}z_2^2 + 24z_1^{-4}z_2^4 + 9, \\ \langle x^4(z_1)x^4(z_2)x^4(z_3) \rangle_\omega &= 27 \cdot 8z_1^{-2}z_2^2 + 63 \cdot 32z_1^{-2}z_2^{-2}z_3^4 \\ &\quad + 351 \cdot 8z_1^{-2}z_3^2 + 9 \cdot 8z_1^{-4}z_2^4 + 63 \cdot 32z_1^{-4}z_2^2z_3^2 + 369 \cdot 8z_1^{-4}z_3^4 \\ &\quad + 27 \cdot 8z_2^{-2}z_3^2 + 9 \cdot 8z_2^{-4}z_3^4 + 27. \end{aligned} \quad (3B.1)$$

The cumulants are

$$\begin{aligned} \langle x^4(z_1)x^4(z_2) \rangle_{\omega,c} &= 72z_1^{-2}z_2^2 + 24z_1^{-4}z_2^4, \\ \langle x^4(z_1)x^4(z_2)x^4(z_3) \rangle_{\omega,c} &= 288(7z_1^{-2}z_2^{-2}z_3^4 + 9z_1^{-2}z_3^2 + 7z_1^{-4}z_2^2z_3^2 + 10z_1^{-4}z_3^4). \end{aligned} \quad (3B.2)$$

The powers of z show by how many steps the intermediate states have been excited. They determine the energy denominators in the formulas (3.518) and (3.519). Apart from a factor $(g/4)^n$ and a

factor $1/(2\omega)^{2n}$ which carries the correct length scale of $x(z)$, the energy shifts $\Delta E = \Delta_1 E_0 + \Delta_2 E_0 + \Delta_3 E_0$ are thus found to be given by

$$\begin{aligned}\Delta_1 E_0 &= 3, \\ \Delta_2 E_0 &= -\left(72 \cdot \frac{1}{2} + 24 \cdot \frac{1}{4}\right), \\ \Delta_3 E_0 &= 288 \left(7 \cdot \frac{1}{2} \cdot \frac{1}{4} + 9 \cdot \frac{1}{2} \cdot \frac{1}{2} + 7 \cdot \frac{1}{4} \cdot \frac{1}{2} + 10 \cdot \frac{1}{4} \cdot \frac{1}{4}\right) = 333 \cdot 4.\end{aligned}\tag{3B.3}$$

Between excited states, the calculation is somewhat more tedious and yields

$$\langle x^4(z) \rangle_\omega = 6n^2 + 6n + 3,\tag{3B.4}$$

$$\begin{aligned}\langle x^4(z_1)x^4(z_2) \rangle_{\omega,c} &= (16n^4 + 96n^3 + 212n^2 + 204n + 72)z_1^{-2}z_2^2 \\ &+ (n^4 + 10n^3 + 35n^2 + 50n + 24)z_1^{-4}z_2^4 \\ &+ (n^4 - 6n^3 + 11n^2 - 6n)z_1^4z_2^{-4} \\ &+ (16n^4 - 32n^3 + 20n^2 - 4n)z_1^2z_2^{-2},\end{aligned}\tag{3B.5}$$

$$\begin{aligned}\langle x^4(z_1)x^4(z_2)x^4(z_3) \rangle_{\omega,c} &= [(16n^6 + 240n^5 + 1444n^4 + 4440n^3 + 7324n^2 + 6120n + 2016) \\ &\quad \times (z_1^{-2}z_2^{-2}z_3^4 + z_1^{-4}z_2^2z_3^2) \\ &+ (384n^5 + 2880n^4 + 8544n^3 + 12528n^2 + 9072n + 2592)z_1^{-2}z_3^2 \\ &+ (48n^5 + 600n^4 + 2880n^3 + 6600n^2 + 7152n + 2880)z_1^{-4}z_3^4 \\ &+ (16n^6 - 144n^5 + 484n^4 - 744n^3 + 508n^2 - 120n)z_1^4z_2^{-2}z_3^{-2} \\ &+ (-48n^5 + 360n^4 - 960n^3 + 1080n^2 - 432n)z_1^4z_3^{-4} \\ &+ (16n^6 + 48n^5 + 4n^4 - 72n^3 - 20n^2 + 24n)z_1^2z_2^{-4}z_3^2 \\ &+ (-384n^5 + 960n^4 - 864n^3 + 336n^2 - 48n)z_1^2z_3^{-2} \\ &+ (16n^6 - 144n^5 + 484n^4 - 744n^3 + 508n^2 - 120n)z_1^2z_2^2z_3^{-4} \\ &+ (16n^6 + 48n^5 + 4n^4 - 72n^3 - 20n^2 + 24n)z_1^{-2}z_2^4z_3^{-2}].\end{aligned}\tag{3B.6}$$

From these we obtain the reduced energy shifts:

$$\Delta_1 E_0 = 6n^2 + 6n + 3,\tag{3B.7}$$

$$\begin{aligned}\Delta_2 E_0 &= -(16n^4 + 96n^3 + 212n^2 + 204n + 72) \cdot \frac{1}{2} \\ &\quad -(n^4 + 10n^3 + 35n^2 + 50n + 24) \cdot \frac{1}{4} \\ &\quad -(n^4 - 6n^3 + 11n^2 - 6n) \cdot \frac{-1}{4} \\ &\quad -(16n^4 - 32n^3 + 20n^2 - 4n) \cdot \frac{-1}{2} \\ &= 2 \cdot (34n^3 + 51n^2 + 59n + 21),\end{aligned}\tag{3B.8}$$

$$\begin{aligned}\Delta_3 E_0 &= [(16n^6 + 240n^5 + 1444n^4 + 4440n^3 + 7324n^2 + 6120n + 2016) \cdot (\frac{1}{2} \cdot \frac{1}{4} + \frac{1}{4} \cdot \frac{1}{2}) \\ &\quad + (384n^5 + 2880n^4 + 8544n^3 + 12528n^2 + 9072n + 2592) \cdot \frac{1}{2} \cdot \frac{1}{2} \\ &\quad + (48n^5 + 600n^4 + 2880n^3 + 6600n^2 + 7152n + 2880) \cdot \frac{1}{4} \cdot \frac{1}{4} \\ &\quad + (16n^6 - 144n^5 + 484n^4 - 744n^3 + 508n^2 - 120n) \cdot \frac{1}{4} \cdot \frac{1}{2} \\ &\quad + (-48n^5 + 360n^4 - 960n^3 + 1080n^2 - 432n) \cdot \frac{1}{4} \cdot \frac{1}{4} \\ &\quad + (16n^6 + 48n^5 + 4n^4 - 72n^3 - 20n^2 + 24n) \cdot \frac{1}{2} \cdot \frac{1}{4} \\ &\quad + (-384n^5 + 960n^4 - 864n^3 + 336n^2 - 48n) \cdot \frac{1}{2} \cdot \frac{1}{2} \\ &\quad + (16n^6 - 144n^5 + 484n^4 - 744n^3 + 508n^2 - 120n) \cdot \frac{1}{2} \cdot \frac{1}{4} \\ &\quad + (16n^6 + 48n^5 + 4n^4 - 72n^3 - 20n^2 + 24n) \cdot \frac{1}{2} \cdot \frac{-1}{2}] \\ &= 4 \cdot 3 \cdot (125n^4 + 250n^3 + 472n^2 + 347n + 111).\end{aligned}\tag{3B.9}$$

Appendix 3C Recursion Relations for Perturbation Coefficients of Anharmonic Oscillator

Bender and Wu²⁵ were the first to solve to high orders recursion relations for the perturbation coefficients of the ground state energy of an anharmonic oscillator with a potential $x^2/2 + gx^4/4$. Their relations are similar to Eqs. (3.537), (3.538), and (3.539), but not the same. Extending their method, we derive here a recursion relation for the perturbation coefficients of all energy levels of the anharmonic oscillator in any number of dimensions D , where the radial potential is $l(l+D-2)/2r^2 + r^2/2 + (g/2)(a_4r^4 + a_6r^6 + \dots + a_{2q}x^{2q})$, where the first term is the centrifugal barrier of angular momentum l in D dimensions. We shall do this in several steps.

3C.1 One-Dimensional Interaction x^4

In natural physical units with $\hbar = 1, \omega = 1, M = 1$, the Schrödinger equation to be solved reads

$$\left(-\frac{1}{2}\frac{d^2}{dx^2} + \frac{1}{2}x^2 + gx^4\right)\psi^{(n)}(x) = E^{(n)}\psi^{(n)}(x). \quad (3C.1)$$

At $g = 0$, this is solved by the harmonic oscillator wave functions

$$\psi^{(n)}(x, g = 0) = N^n e^{-x^2/2} H_n(x), \quad (3C.2)$$

with proper normalization constant N^n , where $H_n(x)$ are the Hermite polynomial of n th degree

$$H_n(x) = \sum_{p=0}^n h_n^p x^p. \quad (3C.3)$$

Generalizing this to the anharmonic case, we solve the Schrödinger equation (3C.1) with the power series ansatz

$$\psi^{(n)}(x) = e^{-x^2/2} \sum_{k=0}^{\infty} (-g)^k \Phi_k^{(n)}(x), \quad (3C.4)$$

$$E^{(n)} = \sum_{k=0}^{\infty} g^k E_k^{(n)}. \quad (3C.5)$$

To make room for derivative symbols, the superscript of $\Phi_k^{(n)}(x)$ is now dropped. Inserting (3C.4) and (3C.5) into (3C.1) and equating the coefficients of equal powers of g , we obtain the equations

$$x\Phi_k'(x) - n\Phi_k(x) = \frac{1}{2}\Phi_k''(x) - x^4\Phi_{k-1}(x) + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} \Phi_{k-k'}(x), \quad (3C.6)$$

where we have inserted the unperturbed energy

$$E_0^{(n)} = n + 1/2, \quad (3C.7)$$

and defined $\Phi_k(x) \equiv 0$ for $k < 0$. The functions $\Phi_k(x)$ are anharmonic versions of the Hermite polynomials. They turn out to be polynomials of $(4k+n)$ th degree:

$$\Phi_k(x) = \sum_{p=0}^{4k+n} A_k^p x^p. \quad (3C.8)$$

²⁵C.M. Bender and T.T. Wu, Phys. Rev. 184, 1231 (1969); Phys. Rev. D 7, 1620 (1973).

In a more explicit notation, the expansion coefficients A_k^p would of course carry the dropped superscript of $\Phi_k^{(n)}$. All higher coefficients vanish:

$$A_k^p \equiv 0 \quad \text{for } p \geq 4k + n + 1. \quad (3C.9)$$

From the harmonic wave functions (3C.2),

$$\Phi_0(x) = N^n H_n(x) = N^n \sum_{p=0}^n h_n^p x^p, \quad (3C.10)$$

we see that the recursion starts with

$$A_0^p = h_n^p N^n. \quad (3C.11)$$

For levels with an even principal quantum number n , the functions $\Phi_k(x)$ are symmetric. It is convenient to choose the normalization $\psi^{(n)}(0) = 1$, such that $N^n = 1/h_n^0$ and

$$A_k^0 = \delta_{0k}. \quad (3C.12)$$

For odd values of n , the wave functions $\Phi_k(x)$ are antisymmetric. Here we choose the normalization $\psi^{(n)'}(0) = 3$, so that $N^n = 3/h_n^1$ and

$$A_k^1 = 3\delta_{0k}. \quad (3C.13)$$

Defining

$$A_k^p \equiv 0 \quad \text{for } p < 0 \quad \text{or} \quad k < 0, \quad (3C.14)$$

we find from (3C.6), by comparing coefficients of x^p ,

$$(p-n)A_k^p = \frac{1}{2}(p+2)(p+1)A_k^{p+2} + A_{k-1}^{p-4} + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} A_{k-k'}^p. \quad (3C.15)$$

The last term on the right-hand side arises after exchanging the order of summation as follows:

$$\sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} \sum_{p=0}^{4(k-k')+n} A_{k-k'}^p x^p = \sum_{p=0}^{4k+n} x^p \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} A_{k-k'}^p. \quad (3C.16)$$

For even n , Eq. (3C.15) with $p = 0$ and $k > 0$ yields [using (3C.14) and (3C.12)] the desired expansion coefficients of the energies

$$E_k^{(n)} = -(-1)^k A_k^2. \quad (3C.17)$$

For odd n , we take Eq. (3C.15) with $p = 1$ and odd $k > 0$ and find [using (3C.13) and (3C.14)] the expansion coefficients of the energies:

$$E_k^{(n)} = -(-1)^k A_k^3. \quad (3C.18)$$

For even n , the recursion relations (3C.15) obviously relate only coefficients carrying even indices with each other. It is therefore useful to set

$$n = 2n', \quad p = 2p', \quad A_k^{2p'} = C_k^{p'}, \quad (3C.19)$$

leading to

$$2(p' - n')C_k^{p'} = (2p' + 1)(p' + 1)C_k^{p'+1} + C_{k-1}^{p'-2} - \sum_{k'=1}^k C_{k'}^1 C_{k-k'}^{p'}. \quad (3C.20)$$

For odd n , the substitution

$$n = 2n' + 1, \quad p = 2p' + 1, \quad A_k^{2p'+1} = C_k^{p'}, \quad (3C.21)$$

leads to

$$2(p' - n')C_k^{p'} = (2p' + 3)(p' + 1)C_k^{p'+1} + C_{k-1}^{p'-2} - \sum_{k'=1}^k C_{k'}^1 C_{k-k'}^{p'}. \quad (3C.22)$$

The rewritten recursion relations (3C.20) and (3C.22) are the same for even and odd n , except for the prefactor of the coefficient $C_k^{p'+1}$. The common initial values are

$$C_0^{p'} = \begin{cases} h_n^{2p'}/h_n^0 & \text{for } 0 \leq p' \leq n', \\ 0 & \text{otherwise.} \end{cases} \quad (3C.23)$$

The energy expansion coefficients are given in either case by

$$E_k^{(n)} = -(-1)^k C_k^1. \quad (3C.24)$$

The solution of the recursion relations proceeds in three steps as follows. Suppose we have calculated for some value of k all coefficients $C_{k-1}^{p'}$ for an upper index in the range $1 \leq p' \leq 2(k-1) + n'$.

In a first step, we find $C_k^{p'}$ for $1 \leq p' \leq 2k + n'$ by solving Eq. (3C.20) or (3C.22), starting with $p' = 2k + n'$ and lowering p' down to $p' = n' + 1$. Note that the knowledge of the coefficients C_k^1 (which determine the yet unknown energies and are contained in the last term of the recursion relations) is not required for $p' > n'$, since they are accompanied by factors $C_0^{p'}$ which vanish due to (3C.23).

Next we use the recursion relation with $p' = n'$ to find equations for the coefficients C_k^1 contained in the last term. The result is, for even k ,

$$C_k^1 = \left[(2n' + 1)(n' + 1)C_k^{n'+1} + C_{k-1}^{n'-2} - \sum_{k'=1}^{k-1} C_{k'}^1 C_{k-k'}^{n'} \right] \frac{1}{C_0^{n'}}. \quad (3C.25)$$

For odd k , the factor $(2n' + 1)$ is replaced by $(2n' + 3)$. These equations contain once more the coefficients $C_k^{n'}$.

Finally, we take the recursion relations for $p' < n'$, and relate the coefficients $C_k^{n'-1}, \dots, C_k^1$ to $C_k^{n'}$. Combining the results we determine from Eq. (3C.24) all expansion coefficients $E_k^{(n)}$.

The relations can easily be extended to interactions which are an arbitrary linear combination

$$V(x) = \sum_{n=2}^{\infty} a_{2n} \epsilon^n x^{2n}. \quad (3C.26)$$

A short *Mathematica* program solving the relations can be downloaded from the internet.²⁶

The expansion coefficients have the remarkable property of growing, for large order k , like

$$E_k^{(n)} \longrightarrow -\frac{1}{\pi} \sqrt{\frac{6}{\pi}} \frac{12}{n!} (-3)^k \Gamma(k + n + 1/2). \quad (3C.27)$$

This will be shown in Eq. (17.323). Such a factorial growth implies the perturbation expansion to have a zero radius of convergence. The reason for this will be explained in Section 17.10. At the expansion point $g = 0$, the energies possess an essential singularity. In order to extract meaningful numbers from a Taylor series expansion around such a singularity, it will be necessary to find a convergent resummation method. This will be provided by the variational perturbation theory to be developed in Section 5.14.

²⁶See <http://www.physik.fu-berlin/~kleinert/b3/programs>.

3C.2 General One-Dimensional Interaction

Consider now an arbitrary interaction which is expandable in a power series

$$v(x) = \sum_{k=1}^{\infty} g^k v_{k+2} x^{k+2}. \quad (3C.28)$$

Note that the coupling constant corresponds now to the square root of the previous one, the lowest interaction terms being $gv_3x^3 + g^2v_4x^4 + \dots$. The powers of g count the number of loops of the associated Feynman diagrams. Then Eqs. (3C.6) and (3C.15) become

$$x\Phi'_k(x) - n\Phi_k(x) = \frac{1}{2}\Phi''_k(x) - \sum_{k'=1}^k (-1)^{k'} v_{k'+2} x^{k'+2} \Phi_{k-k'} + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} \Phi_{k-k'}(x), \quad (3C.29)$$

and

$$(p-n)A_k^p = \frac{1}{2}(p+2)(p+1)A_k^{p+2} - \sum_{k'=1}^k (-1)^{k'} v_{k'+2} A_{k-k'}^{p-j-2} + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} A_{k-k'}^p. \quad (3C.30)$$

The expansion coefficients of the energies are, as before, given by (3C.17) and (3C.18) for even and odd n , respectively, but the recursion relation (3C.30) has to be solved now in full.

3C.3 Cumulative Treatment of Interactions x^4 and x^3

There exists a slightly different recursive treatment which we shall illustrate for the simplest mixed interaction potential

$$V(x) = \frac{M}{2}\omega^2 x^2 + gv_3x^3 + g^2v_4x^4. \quad (3C.31)$$

Instead of the ansatz (3C.4) we shall now factorize the wave function of the ground state as follows:

$$\psi^{(n)}(x) = \left(\frac{M\omega}{\pi\hbar}\right)^{1/4} \exp\left[-\frac{M\omega}{2\hbar}x^2 + \phi^{(n)}(x)\right], \quad (3C.32)$$

i.e., we allow for powers series expansion in the exponent:

$$\phi^{(n)}(x) = \sum_{k=1}^{\infty} g^k \phi_k^{(n)}(x). \quad (3C.33)$$

We shall find that this expansion contains fewer terms than in the Bender-Wu expansion of the correction factor in Eq. (3C.4). For completeness, we keep here physical dimensions with explicit constants \hbar, ω, M .

Inserting (3C.32) into the Schrödinger equation

$$\left[-\frac{\hbar^2}{2M}\frac{d^2}{dx^2} + \left(\frac{M}{2}\omega^2 x^2 + gv_3x^3 + g^2v_4x^4\right) - E^{(n)}\right]\psi^{(n)}(x) = 0, \quad (3C.34)$$

we obtain, after dropping everywhere the superscript (n) , the differential equation for $\phi^{(n)}(x)$:

$$-\frac{\hbar^2}{2M}\phi''(x) + \hbar\omega x\phi'(x) - \frac{\hbar^2}{2M}[\phi'(x)]^2 + gv_3x^3 + g^2v_4x^4 = n\hbar\omega + \epsilon, \quad (3C.35)$$

where ϵ denotes the correction to the harmonic energy

$$E = \hbar\omega\left(n + \frac{1}{2}\right) + \epsilon. \quad (3C.36)$$

We shall calculate ϵ as a power series in g :

$$\epsilon = \sum_{k=1}^{\infty} g^k \epsilon_k. \quad (3C.37)$$

From now on we shall consider only the ground state with $n = 0$. Inserting expansion (3C.33) into (3C.35), and comparing coefficients, we obtain the infinite set of differential equations for $\phi_k(x)$:

$$-\frac{\hbar^2}{2M}\phi_k''(x) + \hbar\omega x\phi_k'(x) - \frac{\hbar^2}{2M}\sum_{l=1}^{k-1}\phi_{k-l}'(x)\phi_l'(x) + \delta_{k,1}v_3x^3 + \delta_{k,2}v_4x^4 = \epsilon_k. \quad (3C.38)$$

Assuming that $\phi_k(x)$ is a polynomial, we can show by induction that its degree cannot be greater than $k + 2$, i.e.,

$$\phi_k(x) = \sum_{m=1}^{\infty} c_m^{(k)} x^m, \quad \text{with } c_m^{(k)} \equiv 0 \quad \text{for } m > k + 2, \quad (3C.39)$$

The lowest terms $c_0^{(k)}$ have been omitted since they will be determined at the end the normalization of the wave function $\psi(x)$. Inserting (3C.39) into (3C.38) for $k = 1$, we find

$$c_1^{(1)} = -\frac{v_3}{M\omega^2}, \quad c_2^{(1)} = 0, \quad c_3^{(1)} = -\frac{v_3}{3\hbar\omega}, \quad \epsilon_1 = 0. \quad (3C.40)$$

For $k = 2$, we obtain

$$c_1^{(2)} = 0, \quad c_2^{(2)} = \frac{7v_3^2}{8M^2\omega^4} - \frac{3v_4}{4M\omega^2}, \quad c_3^{(2)} = 0, \quad c_4^{(2)} = \frac{v_3^2}{8M\hbar\omega^3} - \frac{v_4}{4\hbar\omega}, \quad (3C.41)$$

$$\epsilon_2 = -\frac{11v_3^2\hbar^2}{8M^3\omega^4} + \frac{3v_4\hbar^2}{4M^2\omega^2}. \quad (3C.42)$$

For the higher-order terms we must solve the recursion relations

$$c_m^{(k)} = \frac{(m+2)(m+1)\hbar}{2mM\omega} c_{m+2}^{(k)} + \frac{\hbar}{2mM\omega} \sum_{l=1}^{k-1} \sum_{n=1}^{m+1} n(m+2-n) c_n^{(l)} c_{m+2-n}^{(k-l)}, \quad (3C.43)$$

$$\epsilon_k = -\frac{\hbar^2}{M} c_2^{(k)} - \frac{\hbar^2}{2M} \sum_{l=1}^{k-1} c_1^{(l)} c_1^{(k-l)}. \quad (3C.44)$$

Evaluating this for $k = 3$ yields

$$c_1^{(3)} = -\frac{5v_3^3\hbar}{M^4\omega^7} + \frac{6v_3v_4\hbar}{M^3\omega^5}, \quad c_2^{(3)} = 0, \quad c_3^{(3)} = -\frac{13v_3^3}{12M^3\omega^6} + \frac{3v_3v_4}{2M^2\omega^4}, \\ c_4^{(3)} = 0, \quad c_5^{(3)} = -\frac{v_3^3}{10M^2\hbar\omega^5} + \frac{v_3v_4}{5M\hbar\omega^3}, \quad \epsilon_3 = 0, \quad (3C.45)$$

and for $k = 4$:

$$c_1^{(4)} = 0, \quad c_2^{(4)} = \frac{305v_3^4\hbar}{32M^5\omega^9} - \frac{123v_3^2v_4\hbar}{8M^4\omega^7} + \frac{21v_4^2\hbar}{8M^3\omega^5}, \quad c_3^{(4)} = 0, \quad c_4^{(4)} = \frac{99v_3^4}{64M^4\omega^8} - \frac{47v_3^2v_4}{16M\omega^6} + \frac{11v_4^2}{16M^2\omega^4}, \\ c_5^{(4)} = 0, \quad c_6^{(4)} = \frac{5v_3^4}{48M^3\hbar\omega^7} - \frac{v_3^2v_4}{4M^2\hbar\omega^5} + \frac{v_4^2}{12M\hbar\omega^3}, \quad (3C.46)$$

$$\epsilon_4 = -\frac{465v_3^4\hbar^3}{32M^6\omega^9} + \frac{171v_3^2v_4\hbar^3}{8M^5\omega^7} - \frac{21v_4^2\hbar^3}{8M^4\omega^5}. \quad (3C.47)$$

The general form of the coefficients is, now in natural units with $\hbar = 1$, $M = 1$,:

$$c_m^{(k)} = \sum_{\lambda=0}^{\lfloor k/2 \rfloor} \frac{v_3^{k-2\lambda} v_4^\lambda}{\omega^{5k/2-m/2-2\lambda}} c_{m,\lambda}^{(k)}, \quad \text{with } c_{m,\lambda}^{(k)} \equiv 0 \text{ for } m > k+2, \text{ or } \lambda > \left\lfloor \frac{k}{2} \right\rfloor, \quad (3C.48)$$

$$\epsilon_k = \sum_{\lambda=0}^{\lfloor k/2 \rfloor} \frac{v_3^{k-2\lambda} v_4^\lambda}{\omega^{5k/2-1-2\lambda}} \epsilon_{k,\lambda}. \quad (3C.49)$$

This leads to the recursion relations

$$c_{m,\lambda}^{(k)} = \frac{(m+2)(m+1)}{2m} c_{m+2,\lambda}^{(k)} + \frac{1}{2m} \sum_{l=1}^{k-1} \sum_{n=1}^{m+1} \sum_{\lambda'=0}^{\lambda} n(m+2-n) c_{n,\lambda-\lambda'}^{(l)} c_{m+2-n,\lambda'}^{(k-l)}, \quad (3C.50)$$

with $c_{m,\lambda}^{(k)} \equiv 0$ for $m > k+2$ or $\lambda > \lfloor k/2 \rfloor$. The starting values follow by comparing (3C.40) and (3C.41) with (3C.48):

$$c_{1,0}^{(1)} = -1, \quad c_{2,0}^{(1)} = 0, \quad c_{3,0}^{(1)} = -\frac{1}{3}, \quad (3C.51)$$

$$\begin{aligned} c_{1,0}^{(2)} &= 0, & c_{1,1}^{(2)} &= 0, & c_{2,0}^{(2)} &= \frac{7}{8}, & c_{2,1}^{(2)} &= -\frac{3}{4}, \\ c_{3,0}^{(2)} &= 0, & c_{3,1}^{(2)} &= 0, & c_{4,0}^{(2)} &= \frac{1}{8}, & c_{4,1}^{(2)} &= -\frac{1}{4}. \end{aligned} \quad (3C.52)$$

The expansion coefficients $\epsilon_{k,\lambda}$ for the energy corrections ϵ_k are obtained by inserting (3C.49) and (3C.48) into (3C.44) and going to natural units:

$$\epsilon_{k,\lambda} = -c_{2,\lambda}^{(k)} - \frac{1}{2} \sum_{l=1}^{k-1} \sum_{\lambda'=0}^{\lambda} c_{1,\lambda-\lambda'}^{(l)} c_{1,\lambda'}^{(k-l)}. \quad (3C.53)$$

Table 3.1 shows the nonzero even energy corrections ϵ_k up to the tenth order.

3C.4 Ground-State Energy with External Current

In the presence of a constant external current j , the time-independent Schrödinger reads

$$-\frac{\hbar^2}{2M} \psi''(x) + \left(\frac{M}{2} \omega^2 x^2 + g v_3 x^3 + g^2 v_4 x^4 - jx \right) \psi(x) = E \psi(x). \quad (3C.54)$$

For zero coupling constant $g = 0$, we may simply introduce the new variables x' and E' :

$$x' = x - \frac{j}{M\omega^2} \quad \text{and} \quad E' = E + \frac{j^2}{2M\omega^2}, \quad (3C.55)$$

and the system becomes a harmonic oscillator in x' with energy $E' = \hbar\omega/2$. Thus we make the ansatz for the wave function

$$\psi(x) \propto e^{\phi(x)}, \quad \text{with } \phi(x) = \frac{j}{\hbar\omega} x - \frac{M\omega}{2\hbar} x^2 + \sum_{k=1}^{\infty} g^k \phi_k(x), \quad (3C.56)$$

and for the energy

$$E(j) = \frac{\hbar\omega}{2} - \frac{j^2}{2M\omega^2} + \sum_{k=1}^{\infty} g^k \epsilon_k. \quad (3C.57)$$

k	ϵ_k
2	$\frac{-11v_3^2 + 6v_4\omega^2}{8\omega^4}$
4	$-\frac{465v_3^4 - 684v_3^2v_4\omega^2 + 84v_4^2\omega^4}{32\omega^9}$
6	$\frac{-39709v_3^6 + 91014v_3^4v_4\omega^2 - 47308v_3^2v_4^2\omega^4 + 2664v_4^3\omega^6}{128\omega^{14}}$
8	$\frac{-3(6416935v_3^8 - 19945048v_3^6v_4\omega^2 + 18373480v_3^4v_4^2\omega^4 + 4962400v_3^2v_4^3\omega^6 - 164720v_4^4\omega^8)}{(2048\omega^{19})}$
10	$\frac{(-29444491879v_3^{10} + 11565716526v_3^8v_4\omega^2 - 15341262168v_3^6v_4^2\omega^4 + 7905514480v_3^4v_4^3\omega^6 - 1320414512v_3^2v_4^4\omega^8 + 29335392v_4^5\omega^{10})}{(8192\omega^{24})}$

Table 3.1 Expansion coefficients for the ground-state energy of the anharmonic oscillator (3C.31) up to the 10th order.

The equations (3C.38) become now

$$-\frac{\hbar^2}{2M}\phi_k''(x) - \frac{\hbar^2}{2M}\sum_{l=1}^{k-1}\phi_{k-l}'(x)\phi_l'(x) + \left(\hbar\omega x - \frac{j\hbar}{M\omega}\right)\phi_k'(x) + \delta_{k,1}v_3x^3 + \delta_{k,2}v_4x^4 = \epsilon_k. \quad (3C.58)$$

The results are now for $k = 1$

$$c_1^{(1)} = -\frac{v_3}{M\omega^2} - \frac{j^2v_3}{M^2\hbar\omega^5}, \quad c_2^{(1)} = -\frac{jev_3}{2M\hbar\omega^3}, \quad c_3^{(1)} = -\frac{v_3}{3\hbar\omega}, \quad \epsilon_1 = \frac{3\hbar jv_3}{2M\omega^3} + \frac{j^3v_3}{M^3\omega^6}, \quad (3C.59)$$

and for $k = 2$:

$$\begin{aligned} c_1^{(2)} &= \frac{17jv_3^2}{4M^3\omega^6} + \frac{4j^3v_3^2}{M^4\hbar\omega^9} - \frac{5jv_4}{2M^2\omega^4} - \frac{j^3v_4}{M^3\hbar\omega^7}, \\ c_2^{(2)} &= \frac{7v_3^2}{8M^2\omega^4} + \frac{3j^2v_3^2}{2M^3\hbar\omega^7} - \frac{3v_4}{4M\omega^2} - \frac{j^2v_4}{2M^2\hbar\omega^5}, \\ c_3^{(2)} &= \frac{jev_3^2}{2M^2\hbar\omega^5} - \frac{jev_4}{3M\hbar\omega^3}, \quad c_4^{(2)} = \frac{v_3^2}{8M\hbar\omega^3} - \frac{v_4}{4\hbar\omega}, \\ \epsilon_2 &= -\frac{11\hbar^2v_3^2}{8M^3\omega^4} - \frac{27\hbar j^2v_3^2}{4M^4\omega^7} - \frac{9j^4v_3^2}{2M^5\omega^{10}} + \frac{3\hbar^2v_4}{4M^2\omega^2} + \frac{3\hbar j^2v_4}{M^3\omega^5} + \frac{j^4v_4}{M^4\omega^8}. \end{aligned} \quad (3C.60)$$

The recursive equations (3C.43) and (3C.44) become

$$\begin{aligned} c_m^{(k)} &= \frac{(m+2)(m+1)\hbar}{2mM\omega}c_{m+2}^{(k)} + \frac{\hbar}{2mM\omega}\sum_{l=1}^{k-1}\sum_{n=1}^{m+1}n(m+2-n)c_n^{(l)}c_{m+2-n}^{(k-l)} \\ &\quad + \frac{j(m+1)}{Mm\omega^2}c_{m+1}^{(k)}, \end{aligned} \quad (3C.61)$$

$$\epsilon_k = -\frac{j\hbar}{M\omega}c_1^{(k)} - \frac{\hbar^2}{M}c_2^{(k)} - \frac{\hbar^2}{2M}\sum_{l=1}^{k-1}c_1^{(l)}c_1^{(k-l)}. \quad (3C.62)$$

Table 3.2 shows the energy corrections ϵ_k in the presence of an external current up to the sixth order using natural units, $\hbar = 1$, $M = 1$.

k	ϵ_k
1	$\frac{v_3j(2j^2 + 3\omega^3)}{2\omega^6}$
2	$\frac{2v_4\omega^2(4j^4 + 12j^2\omega^3 + 3\omega^6) - v_3^2(36j^4 + 54j^2\omega^3 + 11\omega^6)}{8\omega^{10}}$
3	$\frac{v_3j[3v_3^2(36j^4 + 63j^2\omega^3 + 22\omega^6) - 2v_4\omega^2(24j^4 + 66j^2\omega^3 + 31\omega^6)]}{4\omega^{14}}$
4	$\frac{[36v_3^2v_4\omega^2(112j^6 + 324j^4\omega^3 + 212j^2\omega^6 + 19\omega^9) - 4v_4^2\omega^4(64j^6 + 264j^4\omega^3 + 248j^2\omega^6 + 21\omega^9) - 3v_3^4(2016j^6 + 4158j^4\omega^3 + 2112j^2\omega^6 + 155\omega^9)]}{(32\omega^{10})}$
5	$\frac{v_3j[27v_3^4(1728j^6 + 4158j^4\omega^3 + 2816j^2\omega^6 + 465\omega^9) + 4v_4^2\omega^4(1536j^6 + 6408j^4\omega^3 + 7072j^2\omega^6 + 1683\omega^9) - 12v_3^2v_4\omega^2(3456j^6 + 10908j^4\omega^3 + 9176j^2\omega^6 + 1817\omega^9)]}{(32\omega^{22})}$
6	$\frac{[8v_4^3\omega^6(1536j^8 + 8544j^6\omega^3 + 14144j^4\omega^6 + 6732j^2\omega^9 + 333\omega^{12}) - 4v_3^2v_4^2\omega^4(103680j^8 + 454032j^6\omega^3 + 584928j^4\omega^6 + 221706j^2\omega^9 + 11827\omega^{12}) + 6v_3^4v_4\omega^2(285120j^8 + 991224j^6\omega^3 + 1024224j^4\omega^6 + 323544j^2\omega^9 + 15169\omega^{12}) - v_3^6(1539648j^8 + 4266108j^6\omega^3 + 3649536j^4\omega^6 + 979290j^2\omega^9 + 39709\omega^{12})]}{(128\omega^{26})}$

Table 3.2 Expansion coefficients for the ground-state energy of the anharmonic oscillator (3C.31) in the presence of an external current up to the 6th order.

3C.5 Recursion Relation for Effective Potential

It is possible to derive a recursion relation directly for the zero-temperature effective potential (5.259). To this we observe that according to Eq. (3.774), the fluctuating part of the effective potential is given by the Euclidean path integral

$$e^{-\beta V_{\text{eff}}^{\text{fl}}(X)} = \int \mathcal{D}\delta x \exp\left(-\frac{1}{\hbar}\left\{\mathcal{A}[X+\delta x] - \mathcal{A}[X] - \mathcal{A}_X[X]\delta x - V_{\text{eff}}^{\text{fl}}(X)\delta x\right\}\right). \quad (3C.63)$$

This can be rewritten as [recall (3.771)]

$$e^{-\beta[V_{\text{eff}}(X) - V(X)]} = \oint \mathcal{D}\delta x \exp\left\{-\frac{1}{\hbar}\int_0^{\hbar\beta} d\tau \times \left[\frac{M}{2}\dot{\delta x}^2(\tau) + V(X+\delta x) - V(X) - V'_{\text{eff}}(X)\delta x\right]\right\}. \quad (3C.64)$$

Going back to the integration variable $x = X + \delta x$, and taking all terms depending only on X to the left-hand side, this becomes

$$e^{-\beta[V_{\text{eff}}(X) - V'_{\text{eff}}(X)X]} = \oint \mathcal{D}x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2(\tau) + V(x) - V'_{\text{eff}}(X)x \right] \right\}. \quad (3C.65)$$

In the limit of zero temperature, the right-hand side is equal to $e^{-\beta E^{(0)}(X)}$, where $E^{(0)}(X)$ is the ground state of the Schrödinger equation associated with the path integral. Hence we obtain

$$-\frac{\hbar^2}{2M} \psi''(x) + [V(x) - V'_{\text{eff}}(X)x] \psi(x) = [V_{\text{eff}}(X) - V'_{\text{eff}}(X)X] \psi(x). \quad (3C.66)$$

For the mixed interaction of the previous subsection, this reads

$$\begin{aligned} -\frac{\hbar^2}{2M} \psi''(x) + \left[\frac{M}{2} \omega^2 x^2 + gv_3 x^3 + g^2 v_4 x^4 - V'_{\text{eff}}(X)x \right] \psi(x) \\ = [V_{\text{eff}}(X) - V'_{\text{eff}}(X)X] \psi(x), \end{aligned} \quad (3C.67)$$

and may be solved recursively. We expand the effective potential in powers of g as it is expanded in the coupling constant g :

$$V_{\text{eff}}(X) = \sum_{k=0}^{\infty} g^k V_k(X), \quad (3C.68)$$

and assume $V_k(X)$ to be a polynomial in X :

$$V_k(X) = \sum_{m=0}^{k+2} C_m^{(k)} X^m. \quad (3C.69)$$

Comparison with Eq. (3C.54) shows that we may set $j = V'_{\text{eff}}(X)$ and calculate $V_{\text{eff}}(X) - V'_{\text{eff}}(X)X$ by analogy to the energy in (3C.57). Inserting the ansatz (3C.68), (3C.69) into (3C.67) we find all equations for $V_k(X)$ by comparing coefficients of g^k and X^m . It turns out that for even or odd k , also $V_k(X)$ is even or odd in X , respectively. Table 3.3 shows the first six orders of the effective potential, which have been obtained in this way.

The equations for $V_k(X)$ are obtained as follows. We insert into (3C.67) the ansatz for the wave function $\psi(x) \propto e^{\phi(x)}$ with

$$\phi(x) = \frac{M\omega X}{\hbar} x - \frac{M\omega}{2\hbar} x^2 + \sum_{k=1}^{\infty} g^k \phi_k(x), \quad (3C.70)$$

and expand

$$V_{\text{eff}}(X) = \frac{\hbar\omega}{2} + \frac{M}{2} \omega^2 X^2 + \sum_{k=1}^{\infty} g^k V_k(X), \quad (3C.71)$$

to obtain the set of equations

$$\begin{aligned} -\frac{\hbar^2}{2M} \phi_k''(x) - \frac{\hbar^2}{2M} \sum_{l=1}^{k-1} \phi_{k-l}'(x) \phi_l'(x) + \hbar\omega(x-X) \phi_k'(x) - xV_k'(X) + \delta_{k,1} v_3 x^3 + \delta_{k,2} v_4 x^4 \\ = V_k(X) - V_k'(X)X. \end{aligned} \quad (3C.72)$$

From these we find for $k = 1$:

$$c_1^{(1)} = \frac{v_3}{2M\omega^2} + \frac{2v_3 X^2}{\hbar\omega}, \quad c_2^{(1)} = -\frac{v_3 X}{2\hbar\omega}, \quad c_3^{(1)} = -\frac{v_3}{3\hbar\omega}, \quad V_1(X) = \frac{3v_3 \hbar}{2M\omega} + v_3 X^3, \quad (3C.73)$$

k	$V_k(X)$
0	$\frac{\omega}{2} + \frac{\omega^2}{2}X^2$
1	$v_3X^3 + \frac{3v_3}{2\omega}X$
2	$v_4X^4 - \frac{v_3^2(1 + 9\omega X^2) + v_4\omega^2(3 + 12\omega X^2)}{4\omega^4}$
3	$\frac{v_3X[3v_3^2(4 + 9\omega X^2) - 2v_4\omega^2(13 + 18\omega X^2)]}{4\omega^6}$
4	$-\frac{[4v_4^2\omega^4(21 + 104\omega X^2 + 72\omega^2 X^4) - 12v_3^2v_4\omega^2(13 + 152\omega X^2 + 108\omega^2 X^4) + v_3^4(51 + 864\omega X^2 + 810\omega^2 X^4)]}{(32\omega^9)}$
5	$\frac{3v_3X[9v_3^4(51 + 256\omega X^2 + 126\omega^2 X^4) + 4v_4^2\omega^4(209 + 544\omega X^2 + 216\omega^2 X^4) - 4v_3^2v_4\omega^2(341 + 1296\omega X^2 + 540\omega^2 X^4)]}{(32\omega^{11})}$
6	$\frac{[24v_4^3\omega^6(111 + 836\omega X^2 + 1088\omega^2 X^4 + 288\omega^3 X^6) - 36v_3^2v_4^2\omega^4(365 + 5654\omega X^2 + 8448\omega^2 X^4 + 2160\omega^3 X^6) + 6v_3^4v_4\omega^2(2129 + 46008\omega X^2 + 85248\omega^2 X^4 + 22680\omega^3 X^6) - v_3^6(3331 + 90882\omega X^2 + 207360\omega^2 X^4 + 61236\omega^3 X^6)]}{(128\omega^{14})}$

Table 3.3 Effective potential of the anharmonic oscillator (3C.31) up to the 6th order, expanded in the coupling constant g (in natural units with $\hbar = 1$ and $M = 1$). The lowest terms agree, of course, with the two-loop result (3.770).

and for $k = 2$:

$$c_1^{(2)} = -\frac{13v_3^2X}{4M^2\omega^4} - \frac{2v_3^2X^3}{M\hbar\omega^3} + \frac{7v_4X}{2M\omega^2} + \frac{3v_4X^3}{\hbar\omega}, \quad c_2^{(2)} = \frac{v_3^2}{8M^2\omega^4} - \frac{3v_4}{4M\omega^2} - \frac{v_4X^2}{2\hbar\omega},$$

$$c_3^{(2)} = \frac{v_3^2X}{2M\hbar\omega^3} - \frac{v_4X}{3\hbar\omega}, \quad c_4^{(2)} = \frac{v_3^2}{8M\hbar\omega^3} - \frac{v_4}{4\hbar\omega}, \tag{3C.74}$$

$$V_2(X) = -\frac{\hbar^2v_3^2}{4M^3\omega^4} - \frac{9\hbar v_3^2X^2}{4M^2\omega^3} + \frac{3\hbar^2v_4}{4M^2\omega^2} + \frac{3\hbar v_4X^2}{M\omega} + v_4X^4. \tag{3C.75}$$

For $k \geq 3$, we must solve recursively

$$c_m^{(k)} = \frac{(m+2)(m+1)\hbar}{2mM\omega} c_{m+2}^{(k)} + \frac{\hbar}{2mM\omega} \sum_{l=1}^{k-1} \sum_{n=1}^{m+1} n(m+2-n) c_n^{(l)} c_{m+2-n}^{(k-l)} + \frac{X(m+1)}{m} c_{m+1}^{(k)} \text{ for } m \geq 2 \text{ and with } c_m^{(k)} \equiv 0 \text{ for } m > k+2, \tag{3C.76}$$

$$c_1^{(k)} = \frac{3\hbar}{M\omega} c_3^{(k)} + 2Xc_2^{(k)} + \frac{\hbar}{M\omega} \sum_{l=1}^{k-1} (c_2^{(k-l)} c_1^{(l)} + c_1^{(k-l)} c_2^{(l)}) + \frac{1}{\hbar\omega} V_k'(X), \tag{3C.77}$$

$$\begin{aligned}
V_k(X) &= -\frac{\hbar^2}{M}c_2^{(k)} - \frac{3\hbar^2}{M}Xc_3^{(k)} - 2\hbar\omega X^2c_2^{(k)} - \frac{\hbar^2}{M}X \sum_{l=1}^{k-1} \left(c_2^{(k-l)}c_1^{(l)} + c_1^{(k-l)}c_2^{(l)} \right) \\
&\quad - \frac{\hbar^2}{2M} \sum_{l=1}^{k-1} c_1^{(l)}c_1^{(k-l)}. \tag{3C.78}
\end{aligned}$$

The results are listed in Table 3.3.

3C.6 Interaction r^4 in D -Dimensional Radial Oscillator

It is easy to generalize these relations further to find the perturbation expansions for the eigenvalues of the radial Schrödinger equation of an anharmonic oscillator in D dimensions

$$\left[-\frac{1}{2} \frac{d^2}{dr^2} - \frac{1}{2} \frac{D-1}{r} \frac{d}{dr} + \frac{l(l+D-2)}{2r^2} + \frac{1}{2}r^2 + \frac{g}{4}r^4 \right] R_n(r) = E^{(n)}R_n(r). \tag{3C.79}$$

The case $g = 0$ will be solved in Section 9.2, with the energy eigenvalues

$$E^{(n)} = 2n' + l + D/2 = n + D/2, \quad n = 0, 1, 2, 3, \dots, \quad l = 0, 1, 2, 3, \dots \tag{3C.80}$$

For a fixed principal quantum number $n = 2n_r + l$, the angular momentum runs through $l = 0, 2, \dots, n$ for even, and $l = 1, 3, \dots, n$ for odd n . There are $(n+1)(n+2)/2$ degenerate levels. Removing a factor r^l from $R_n(r)$, and defining $R_n(r) = r^l w_n(r)$, the Schrödinger equation becomes

$$\left(-\frac{1}{2} \frac{d^2}{dr^2} - \frac{1}{2} \frac{2l+D-1}{r} \frac{d}{dr} + \frac{1}{2}r^2 + \frac{g}{4}r^4 \right) w_n(r) = E^{(n)}w_n(r). \tag{3C.81}$$

The second term modifies the differential equation (3C.6) to

$$r\Phi'_k(r) - 2n'\Phi_k(r) = \frac{1}{2}\Phi''_k(r) + \frac{(2l+D-1)}{2r}\Phi'_k(r) + r^4\Phi_{k-1}(r) + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} \Phi_{k-k'}(r). \tag{3C.82}$$

The extra terms change the recursion relation (3C.15) into

$$(p-2n')A_k^p = \frac{1}{2}[(p+2)(p+1) + (p+2)(2l+D-1)]A_k^{p+2} + A_{k-1}^{p-4} + \sum_{k'=1}^k (-1)^{k'} E_{k'}^{(n)} A_{k-k'}^p. \tag{3C.83}$$

For even $n = 2n' + l$ with $l = 0, 2, 4, \dots, n$, we normalize the wave functions by setting

$$C_k^0 = (2l+D)\delta_{0k}, \tag{3C.84}$$

rather than (3C.12), and obtain

$$2(p'-n')C_k^{p'} = [(2p'+1)(p'+1) + (p'+1)(l+D/2-1/2)]C_k^{p'+1} + C_{k-1}^{p'-2} - \sum_{k'=1}^k C_{k'}^1 C_{k-k'}^{p'}, \tag{3C.85}$$

instead of (3C.20).

For odd $n = 2n' + l$ with $l = 1, 3, 5, \dots, n$, the equations analogous to (3C.13) and (3C.22) are

$$C_k^1 = 3(2l+D)\delta_{0k} \tag{3C.86}$$

and

$$2(p'-n')C_k^{p'} = [(2p'+3)(p'+1) + (p'+3/2)(l+D/2-1/2)]C_k^{p'+1} + C_{k-1}^{p'-2} - \sum_{k'=1}^k C_{k'}^1 C_{k-k'}^{p'}. \tag{3C.87}$$

In either case, the expansion coefficients of the energy are given by

$$E_k^{(n)} = -\frac{(-1)^k}{2} \frac{2l+D+1}{2l+D} C_k^1. \tag{3C.88}$$

3C.7 Interaction r^{2q} in D Dimensions

A further extension of the recursion relation applies to interactions $gx^{2q}/4$. Then Eqs. (3C.20) and (3C.22) are changed in the second terms on the right-hand side which become $C_k^{p'-q}$. In a first step, these equations are now solved for $C_k^{p'}$ for $1 \leq p' \leq qk + n$, starting with $p' = qk + n'$ and lowering p' down to $p' = n' + 1$. As before, the knowledge of the coefficients C_k^1 (which determine the yet unknown energies and are contained in the last term of the recursion relations) is not required for $p' > n'$. The second and third steps are completely analogous to the case $q = 2$.

The same generalization applies to the D -dimensional case.

3C.8 Polynomial Interaction in D Dimensions

If the Schrödinger equation has the general form

$$\left[-\frac{1}{2} \frac{d^2}{dr^2} - \frac{1}{2} \frac{D-1}{r} \frac{d}{dr} + \frac{l(l+D-2)}{2r^2} + \frac{1}{2} r^2 + \frac{g}{4} (a_4 r^4 + a_6 r^6 + \dots + a_{2q} r^{2q}) \right] R_n(r) = E^{(n)} R_n(r), \quad (3C.89)$$

we simply have to replace in the recursion relations (3C.85) and (3C.87) the second term on the right-hand side as follows

$$C_{k-1}^{p'-2} \rightarrow a_4 C_{k-1}^{p'-2} + a_6 C_{k-1}^{p'-3} + \dots + a_{2q} C_{k-1}^{p'-q}, \quad (3C.90)$$

and perform otherwise the same steps as for the potential $gr^{2q}/4$ alone.

Appendix 3D Feynman Integrals for $T \neq 0$

The calculation of the Feynman integrals (3.550) can be done straightforwardly with the help of the symbolic program *Mathematica*. The first integral in Eqs. (3.550) is trivial. The second and fourth integrals are simple, since one overall integration over, say, τ_3 yields merely a factor $\hbar\beta$, due to translational invariance of the integrand along the τ -axis. The triple integrals can then be split as

$$\begin{aligned} & \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 d\tau_3 f(|\tau_1 - \tau_2|, |\tau_2 - \tau_3|, |\tau_3 - \tau_1|) \\ &= \hbar\beta \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 f(|\tau_1 - \tau_2|, |\tau_2|, |\tau_1|) \\ &= \hbar\beta \left(\int_0^{\hbar\beta} d\tau_2 \int_0^{\tau_2} d\tau_1 f(\tau_2 - \tau_1, \tau_2, \tau_1) + \int_0^{\hbar\beta} d\tau_2 \int_{\tau_2}^{\hbar\beta} d\tau_1 f(\tau_1 - \tau_2, \tau_2, \tau_1) \right), \end{aligned} \quad (3D.1)$$

to ensure that the arguments of the Green function have the same sign in each term. The lines represent the thermal correlation function

$$G^{(2)}(\tau, \tau') = \frac{\hbar}{2M\omega} \frac{\cosh \omega[|\tau - \tau'| - \hbar\beta/2]}{\sinh(\omega\hbar\beta/2)}. \quad (3D.2)$$

With the dimensionless variable $x \equiv \omega\hbar\beta$, the result for the quantities α_V^{2L} defined in (3.550) in the Feynman diagrams with L lines and V vertices is

$$a^2 = \frac{1}{2} \coth \frac{x}{2}, \quad (3D.3)$$

$$\alpha_2^4 = \frac{1}{8} \frac{1}{\sinh^2 \frac{x}{2}} (x + \sinh x), \quad (3D.4)$$

$$\alpha_3^6 = \frac{1}{64} \frac{1}{\sinh^3 \frac{x}{2}} \left(-3 \cosh \frac{x}{2} + 2 x^2 \cosh \frac{x}{2} + 3 \cosh \frac{3x}{2} + 6 x \sinh \frac{x}{2} \right), \quad (3D.5)$$

$$\alpha_2^8 = \frac{1}{256} \frac{1}{\sinh^4 \frac{x}{2}} (6 x + 8 \sinh x + \sinh 2x), \quad (3D.6)$$

$$\alpha_3^{10} = \frac{1}{4096} \frac{1}{\sinh^5 \frac{x}{2}} \left(-40 \cosh \frac{x}{2} + 24 x^2 \cosh \frac{x}{2} + 35 \cosh \frac{3x}{2} + 5 \cosh \frac{5x}{2} + 72 x \sinh \frac{x}{2} + 12 x \sinh \frac{3x}{2} \right), \quad (3D.7)$$

$$\alpha_3^{12} = \frac{1}{16384} \frac{1}{\sinh^6 \frac{x}{2}} \left(-48 + 32 x^2 - 3 \cosh x + 8 x^2 \cosh x + 48 \cosh 2x + 3 \cosh 3x + 108 x \sinh x \right), \quad (3D.8)$$

$$\alpha_2^6 = \frac{1}{24} \frac{1}{\sinh^2 \frac{x}{2}} (5 + 24 \cosh x), \quad (3D.9)$$

$$\alpha_3^8 = \frac{1}{72} \frac{1}{\sinh^3 \frac{x}{2}} \left(3 x \cosh \frac{x}{2} + 9 \sinh \frac{x}{2} + \sinh \frac{3x}{2} \right), \quad (3D.10)$$

$$\alpha_{3'}^{10} = \frac{1}{2304} \frac{1}{\sinh^4 \frac{x}{2}} (30 x + 104 \sinh x + 5 \sinh 2x). \quad (3D.11)$$

For completeness, we have also listed the integrals α_2^6 , α_3^8 , and $\alpha_{3'}^{10}$, corresponding to the three diagrams

respectively, which occur in perturbation expansions with a cubic interaction potential x^3 . These will appear in a modified version in Chapter 5.

In the low-temperature limit where $x = \omega \hbar \beta \rightarrow \infty$, the x -dependent factors α_V^{2L} in Eqs. (3D.3)–(3D.11) converge towards the constants

$$1/2, \quad 1/4, \quad 3/16, \quad 1/32, \quad 5/(8 \cdot 2^5), \quad 3/(8 \cdot 2^6), \quad 1/12, \quad 1/18, \quad 5/(9 \cdot 2^5), \quad (3D.13)$$

respectively. From these numbers we deduce the relations (3.553) and, in addition,

$$a_2^6 \rightarrow \frac{2}{3} a^6, \quad a_3^8 \rightarrow \frac{8}{9} a^8, \quad a_{3'}^{10} \rightarrow \frac{5}{9} a^{10}. \quad (3D.14)$$

In the high-temperature limit $x \rightarrow 0$, the Feynman integrals $\hbar \beta (1/\omega)^{V-1} a_V^{2L}$ with L lines and V vertices diverge like $\beta^V (1/\beta)^L$. The first V factors are due to the V -integrals over τ , the second are the consequence of the product of $n/2$ factors a^2 . Thus, a_V^{2L} behaves for $x \rightarrow 0$ like

$$a_V^{2L} \propto \left(\frac{\hbar}{M\omega} \right)^L x^{V-1-L}. \quad (3D.15)$$

Indeed, the x -dependent factors α_V^{2L} in (3D.3)–(3D.11) grow like

$$\begin{aligned} \alpha^2 &\approx 1/x + x/12 + \dots, \\ \alpha_2^4 &\approx 1/x + x^3/720, \\ \alpha_3^6 &\approx 1/x + x^5/30240 + \dots, \\ \alpha_2^8 &\approx 1/x^3 + x/120 - x^3/3780 + x^5/80640 + \dots, \\ \alpha_3^{10} &\approx 1/x^3 + x/240 - x^3/15120 + x^7/6652800 + \dots, \end{aligned}$$

$$\begin{aligned}
\alpha_3^{12} &\approx 1/x^4 + 1/240 + x^2/15120 - x^6/4989600 + 701 x^8/34871316480 + \dots, \\
\alpha_2^6 &\approx 1/x^2 + x^2/240 - x^4/6048 + \dots, \\
\alpha_3^8 &\approx 1/x^2 + x^2/720 - x^6/518400 + \dots, \\
\alpha_{3'}^{10} &\approx 1/x^3 + x/360 - x^5/1209600 + 629 x^9/261534873600 + \dots .
\end{aligned} \tag{3D.16}$$

For the temperature behavior of these Feynman integrals see Fig. 3.16. We have plotted the reduced Feynman integrals $\hat{a}_V^{2L}(x)$ in which the low-temperature behaviors (3.553) and (3D.14) have been divided out of a_V^{2L} .

Figure 3.16 Plot of reduced Feynman integrals $\hat{a}_V^{2L}(x)$ as a function of $L/x = Lk_B T/\hbar\omega$. The integrals (3D.4)–(3D.11) are indicated by decreasing dash-lengths.

The integrals (3D.4) and (3D.5) for a_2^4 and a_3^6 can be obtained from the integral (3D.3) for a^2 by the operation

$$\frac{\hbar^n}{n!M^n} \left(-\frac{\partial}{\partial\omega^2} \right)^n = \frac{\hbar^n}{n!M^n} \left(-\frac{1}{2\omega} \frac{\partial}{\partial\omega} \right)^n, \tag{3D.17}$$

with $n = 1$ and $n = 2$, respectively. This follows immediately from the fact that the Green function

$$G_\omega^{(2)}(\tau, \tau') = \frac{1}{\hbar M \beta} \sum_{m=-\infty}^{\infty} e^{-i\omega_m(\tau-\tau')} \frac{\hbar}{\omega_m^2 + \omega^2}, \tag{3D.18}$$

with ω^2 shifted to $\omega^2 + \delta\omega^2$ can be expanded into a geometric series

$$\begin{aligned}
\text{pace-1.9cm} G_{\sqrt{\omega^2 + \delta\omega^2}}^{(2)}(\tau, \tau') &= \frac{1}{\hbar M \beta} \sum_{m=-\infty}^{\infty} e^{-i\omega_m(\tau-\tau')} \left[\frac{\hbar}{\omega_m^2 + \omega^2} - \frac{\delta\omega^2}{\hbar} \frac{\hbar^2}{(\omega_m^2 + \omega^2)^2} \right. \\
&\quad \left. \text{pace1.0cm} + \left(\frac{\delta\omega^2}{\hbar} \right)^2 \frac{\hbar^3}{(\omega_m^2 + \omega^2)^3} + \dots \right],
\end{aligned} \tag{3D.19}$$

which corresponds to a series of convoluted τ -integrals

$$\begin{aligned}
G_{\sqrt{\omega^2 + \delta\omega^2}}^{(2)}(\tau, \tau') &= G_\omega^{(2)}(\tau, \tau') - \frac{M\delta\omega^2}{\hbar} \int_0^{\hbar\beta} d\tau_1 G_\omega^{(2)}(\tau, \tau_1) G_\omega^{(2)}(\tau_1, \tau') \\
&\quad + \left(\frac{M\delta\omega^2}{\hbar} \right)^2 \int_0^{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 d\tau_2 G_\omega^{(2)}(\tau, \tau_1) G_\omega^{(2)}(\tau_1, \tau_2) G_\omega^{(2)}(\tau_2, \tau') + \dots .
\end{aligned} \tag{3D.20}$$

In the diagrammatic representation, the derivatives (3D.17) insert n points into a line. In quantum field theory, this operation is called *mass insertion*. Similarly, the Feynman integral (3D.7) is obtained from (3D.6) via a differentiation (3D.17) with $n = 1$ [see the corresponding diagrams in (3.550)]. A factor 4 must be removed, since the differentiation inserts a point into each of the four

lines which are indistinguishable. Note that from these rules, we obtain directly the relations 1, 2, and 4 of (3.553).

Note that the same type of expansion allows us to derive the three integrals from the one-loop diagram (3.549). After inserting (3D.20) into (3.549) and re-expanding the logarithm we find the series of Feynman integrals

$$\omega^2 + \delta\omega^2 \rightarrow \text{circle} + \frac{M\delta\omega^2}{\hbar} \text{circle with dot} - \left(\frac{M\delta\omega^2}{\hbar}\right)^2 \frac{1}{2} \text{circle with two dots} + \left(\frac{M\delta\omega^2}{\hbar}\right)^3 \frac{1}{3} \text{circle with three dots} - \dots,$$

from which the integrals (3D.3)–(3D.5) can be extracted. As an example, consider the Feynman integral

$$\text{circle with two dots} = \hbar\beta \frac{1}{\omega} a_2^4.$$

It is obtained from the second-order Taylor expansion term of the tracelog as follows:

$$-\frac{1}{2}\hbar\beta \frac{1}{\omega} a_1^4 = \frac{\hbar^2}{2!M^2} \left(\frac{\partial}{\partial\omega^2}\right)^2 [-2\beta V_\omega]. \quad (3D.21)$$

A straightforward calculation, on the other hand, yields once more a_2^4 of Eq. (3D.5).

4

Semiclassical Time Evolution Amplitude

The path integral approach renders a clear intuitive understanding of quantum-mechanical effects in terms of quantum fluctuations, exhibiting precisely how the laws of classical mechanics are modified by these fluctuations. In some limiting situations, the modifications may be small, for instance, if an electron in an atom is highly excited. Its wave packet encircles the nucleus in almost the same way as a point particle in classical mechanics. Then it is relatively easy to calculate quite accurate quantum-mechanical amplitudes by expanding them around classical expressions in powers of the fluctuation width.

4.1 Wentzel-Kramers-Brillouin (WKB) Approximation

In Schrödinger's theory, an important step towards understanding the relation between classical and quantum mechanics consists in proving that the center of a Schrödinger wave packet moves like a classical particle. The approach to the classical limit is described by the so-called *eikonal approximation*, or the *Wentzel-Kramers-Brillouin approximation* (short: *WKB approximation*), which proceeds as follows:

First, one rewrites the time-independent Schrödinger equation of a point particle

$$\left\{ -\frac{\hbar^2}{2M} \nabla^2 - [E - V(\mathbf{x})] \right\} \psi(\mathbf{x}) = 0 \quad (4.1)$$

in the form

$$[-\hbar^2 \nabla^2 - p^2(\mathbf{x})] \psi(\mathbf{x}) = 0, \quad (4.2)$$

where

$$p(\mathbf{x}) \equiv \sqrt{2M[E - V(\mathbf{x})]} \quad (4.3)$$

is the *local classical momentum* of the particle.

In a second step, one re-expresses the wave function as an exponential

$$\psi(\mathbf{x}) = e^{iS(\mathbf{x})/\hbar}. \quad (4.4)$$

For the exponent $S(\mathbf{x})$, called the *eikonal*, the Schrödinger equation amounts to the differential equation :

$$-i\hbar\nabla^2 S(\mathbf{x}) + [\nabla S(\mathbf{x})]^2 - p^2(\mathbf{x}) = 0. \quad (4.5)$$

To solve this equation approximately, one assumes that the function $p(\mathbf{x})$ shows little relative change over the de Broglie wavelength

$$\lambda \equiv \frac{2\pi}{k(\mathbf{x})} \equiv \frac{2\pi\hbar}{p(\mathbf{x})}, \quad (4.6)$$

i.e.,

$$\varepsilon \equiv \frac{2\pi\hbar}{p(\mathbf{x})} \left| \frac{\nabla p(\mathbf{x})}{p(\mathbf{x})} \right| \ll 1. \quad (4.7)$$

This condition is called the *WKB condition*. In the extreme case of $p(\mathbf{x})$ being a constant the condition is certainly fulfilled and the Riccati equation is solved by the trivial eikonal

$$S = \mathbf{p}\mathbf{x} + \text{const}, \quad (4.8)$$

which makes (4.4) a plain wave. For slow variations, the first term in the Riccati equation is much smaller than the others and can be treated systematically in a “smoothness expansion”. Since the small ratio (4.7) carries a prefactor \hbar , the Planck constant may be used to count the powers of the smallness parameter ε , i.e., it may formally be considered as a small expansion parameter.

The limit $\hbar \rightarrow 0$ of the equation determines the lowest-order approximation to the eikonal, $S_0(\mathbf{x})$, by

$$[\nabla S_0(\mathbf{x})]^2 - p^2(\mathbf{x}) = 0. \quad (4.9)$$

Being independent of \hbar , this is a classical equation. Indeed, it is equivalent to the Hamilton-Jacobi differential equation of classical mechanics: For time-independent systems, the action can be written as

$$A(\mathbf{x}, t) = S_0(\mathbf{x}) - tE, \quad (4.10)$$

where $S_0(\mathbf{x})$ is defined by

$$S_0(\mathbf{x}) \equiv \int dt \mathbf{p}(t)\dot{\mathbf{x}}(t), \quad (4.11)$$

and E is the constant energy of the orbit under consideration. The action solves the Hamilton-Jacobi equation (1.64). In three dimensions, it is a function $A(\mathbf{x}, t)$ of the orbital endpoints. According to Eq. (1.62), the derivative of $A(\mathbf{x}, t)$ is equal to the momentum \mathbf{p} . Since E is a constant, the same thing holds for $S_0(\mathbf{x}, t)$. Hence

$$\mathbf{p} \equiv \nabla A(\mathbf{x}) = \nabla S_0(\mathbf{x}). \quad (4.12)$$

In terms of the action A , the Hamilton-Jacobi equation reads

$$\frac{1}{2M}(\nabla A)^2 + V(\mathbf{x}) = -\partial_t A. \quad (4.13)$$

By inserting Eqs. (4.10) and (4.12), we recover Eq. (4.9). This is why $S_0(\mathbf{x})$ is also called the *classical eikonal*.

The corrections to the classical eikonal are calculated most systematically by imagining $\hbar \neq 0$ to be a small quantity and expanding the eikonal around $S_0(x)$ in a power series in \hbar :

$$S = S_0 - i\hbar S_1 + (-i\hbar)^2 S_2 + (-i\hbar)^3 S_3 + \dots \quad (4.14)$$

This is called the *semiclassical expansion* of the eikonal. Inserting it into the Riccati equation, we find the sequence of *WKB equations*

$$\begin{aligned} (\nabla S_0)^2 - p^2 &= 0, \\ \nabla^2 S_0 + 2\nabla S_0 \cdot \nabla S_1 &= 0, \\ \nabla^2 S_1 + (\nabla S_1)^2 + 2\nabla S_0 \cdot \nabla S_2 &= 0, \\ \nabla^2 S_2 + 2\nabla S_1 \cdot \nabla S_2 + 2\nabla S_0 \cdot \nabla S_3 &= 0, \\ &\vdots \\ \nabla^2 S_n + \sum_{m=0}^{n+1} \nabla S_m \cdot \nabla S_{n+1-m} &= 0, \\ &\vdots \end{aligned} \quad (4.15)$$

Note that these equations involve only the vectors

$$\mathbf{q}_n = \nabla S_n \quad (4.16)$$

and allow for a successive determination of S_0, S_1, S_2, \dots , giving higher and higher corrections to the eikonal $S(\mathbf{x})$.

In one dimension we recognize in (4.5) the Riccati differential equation (2.547) fulfilled by $\partial_\tau S(x)$, if we identify x with $\tau\sqrt{2M}$, and $v(\tau)$ with $E - V(\tau)$, where (4.5) reads

$$-i\hbar\partial_\tau[\partial_\tau S(\tau)] + [\partial_\tau S(\tau)]^2 = p^2(\tau) = v(\tau). \quad (4.17)$$

If we re-express the expansion terms (2.552) in terms of $w(\tau) = \sqrt{v(\tau)}$, we may replace $w(\tau), w'(\tau), \dots$ by $p(x), p'(x), \dots$, and find directly

$$\begin{aligned} q_0(x) &= \pm p(x), \quad q_1(x) = -\frac{1}{2} \frac{p'(x)}{p(x)} = \frac{V'}{4(E-V)}, \\ q_2(x) &= \pm \left[\frac{1}{4} \frac{p''(x)}{p^2(x)} - \frac{3}{8} \frac{p'^2(x)}{p^3(x)} \right] = \mp \frac{4V''(E-V) + 5V'^2}{32\sqrt{2M}(E-V)^{5/2}} \equiv \mp p(x)g(x), \\ q_3(x) &= \frac{1}{2} g'(x) = \frac{15V'^3 + 18V'V''(E-V) + 4V'''(E-V)^2}{128M(E-V)^4}. \end{aligned} \quad (4.18)$$

Note that $q_2(x)$ can also be written as

$$q_2(x) = \frac{1}{4S'(x)} \{S', x\},$$

where $\{h, x\}$ denotes the so-called *Schwartz derivative* [1]:

$$\{h, x\} \equiv \frac{h'''}{h'} - \frac{3}{2} \left(\frac{h''}{h'} \right)^2 \quad (4.19)$$

of the function $h(x)$. The equation for $q_2(x)$ defines also the quantity $g(x) \equiv q_2(x)/p(x)$ appearing in the equation for $q_3(x)$.

It is useful to introduce also the expansion

$$q(x) \equiv S'(x) = q_0(x) + \hbar q_1(x) + \hbar^2 q_2(x) + \dots \quad (4.20)$$

Then the eikonal has the expansion

$$S(x) = \int dx q(x) = \pm \int dx p(x) [1 + \hbar^2 g(x)] + \hbar \frac{i}{2} [\log p(x) + \hbar^2 g(x)] \pm \dots \quad (4.21)$$

Keeping only terms up to the order \hbar , which is possible if $\hbar^2 |\epsilon(x)| \ll 1$, we find the (as yet unnormalized) *WKB wave function*

$$\psi_{\text{WKB}}(x) = e^{(i/\hbar) \int^x dx' q(x')} = \frac{1}{\sqrt{p(x)}} e^{\pm(i/\hbar) \int^x dx' p(x')}. \quad (4.22)$$

In the classically accessible regime $V(x) \leq E$, this is an oscillating wave function; in the inaccessible regime $V(x) \geq E$, it decreases or increases exponentially. The transition from one to the other is nontrivial since for $V(x) \approx E$, the WKB approximation breaks down. After some analytic work¹, however, it is possible to derive simple *connection rules* for the linearly independent solutions. Let $k(x) \equiv p(x)/\hbar$ in the oscillating regime and $\kappa(x) \equiv |p(x)|/\hbar$ in the exponential regime. Suppose that there is a crossover at $x = a$ connecting an inaccessible regime on the left of $x = a$ with an accessible one on the right. Then the connection rules are

$$\begin{array}{ccc} V(x) > E & & V(x) < E \\ \frac{1}{\sqrt{\kappa}} e^{-\int_x^a dx' \kappa} & \longleftrightarrow & \frac{2}{\sqrt{k}} \cos \left(\int_a^x dx' k - \frac{\pi}{4} \right), \end{array} \quad (4.23)$$

$$\frac{1}{\sqrt{\kappa}} e^{\int_x^a dx' \kappa} \quad \longleftrightarrow \quad -\frac{1}{\sqrt{k}} \sin \left(\int_a^x dx' k - \frac{\pi}{4} \right). \quad (4.24)$$

In the opposite situation at the point $x = b$, they turn into

$$\begin{array}{ccc} V(x) < E & & V(x) > E \\ \frac{2}{\sqrt{k}} \cos \left(\int_x^b dx' k - \frac{\pi}{4} \right) & \longleftrightarrow & \frac{1}{\sqrt{\kappa}} e^{-\int_b^x dx' \kappa}, \end{array} \quad (4.25)$$

$$-\frac{1}{\sqrt{k}} \sin \left(\int_x^b dx' k - \frac{\pi}{4} \right) \quad \longleftrightarrow \quad \frac{2}{\sqrt{\kappa}} e^{\int_b^x dx' \kappa}. \quad (4.26)$$

¹R.E. Langer, Phys. Rev. 51, 669 (1937). See also W.H. Furry, Phys. Rev. 71, 360 (1947), and the textbooks S. Flügge, *Practical Quantum Mechanics*, Springer, Berlin, 1974; L.I. Schiff, *Quantum Mechanics*, McGraw-Hill, New York, 1955; N. Fröman and P.O. Fröman, *JWKB-Approximation*, North-Holland, Amsterdam, 1965.

The connection rules can be used safely only along the direction of the double arrows.

For their derivation one solves the Schrödinger equation exactly in the neighborhood of the turning points where the potential rises or falls approximately linearly. These solutions are connected with adjacent WKB wave functions. The connection formulas can also be found directly by a formal trick: When approaching the dangerous turning points, one escapes into the complex x -plane and passes around the singularities at a finite distance. This has to be sufficiently large to preserve the WKB condition (4.7), but small enough to allow for the linear approximation of the potential near the turning point. Take for example the connection rule at $x = b$. When approaching the turning point at $x = b$ from the right, the function $\kappa(x)$ is approximately proportional to $\sqrt{x - b}$. Going around this zero in the upper complex half-plane takes $\kappa(x)$ into $ik(x)$ and the wave function $\sqrt{\kappa}^{-1} e^{-\int_b^x dx' \kappa}$ becomes $e^{-i\pi/4} \sqrt{k}^{-1} e^{-i \int_b^x dx' k}$. Going around the turning point in the lower half-plane produces $e^{i\pi/4} \sqrt{k}^{-1} e^{i \int_b^x dx' k}$. The sum of the two terms is $2\sqrt{k}^{-1} \cos(\int_x^b dx' k - \pi/4)$. The argument does not show why one should use the sum rather than the average. This becomes clear only after a more detailed discussion found in quantum-mechanical textbooks². The simplest derivation of the connection formulas is based on the large-distance behaviors (2.625) and (2.630) of wave the function to the right and left of a linearly rising potential and applying this to the linearly rising section of the general potential near the turning point.

In a simple potential well, the function $p(x)$ has two zeros, say one at $x = a$ and one at $x = b$. The bound-state wave functions must satisfy the boundary condition to vanish exponentially fast at $x = \pm\infty$. Imposing these, the connection formulas lead to the *semiclassical* or *Bohr-Sommerfeld quantization rule*

$$\int_a^b dx k(x) = (n + 1/2)\pi, \quad n = 0, \pm 1, \pm 2, \dots \quad (4.27)$$

It was pointed out by Dunham³ that due to the square-root nature of the cut between a and b , this condition implies that the anticlockwise contour integral around the cut over the eikonal expansion (4.21) up to order \hbar , where $q(x) \approx \pm p(x) + i(\hbar/2) \log p(x)$, is an integer multiple of \hbar :

$$\oint dx q(x) = 2\pi n \hbar. \quad (4.28)$$

The contour encloses the classical turning points and no other singularities of $q(x)$. This property ensures the single-valuedness of the wave function $\psi(x) = \exp[iS(x)/\hbar] = \exp[i \int dx q(x)/\hbar]$ at the semiclassical level.

Moreover, the single-valuedness is a necessary property to *all* orders in the expansion (4.21). This makes (4.28) an exact quantization rule.⁴ In fact, in Sub-

²See for example E. Merzbacher, *Quantum Theory*, John Wiley & Sons, New York, 1970, p. 122; M.L. Goldberger and K.M. Watson, *Collision Theory*, John Wiley & Sons, New York, 1964, p. 324. The analytic argument is given in L.D. Landau and E.M. Lifshitz, *Quantum Mechanics*, Pergamon, London, 1965, p. 158.

³J.L. Dunham, Phys. Rev. *41*, 21 (1932)

⁴J.R. Krieger and C. Rosenzweig, Phys. Rev. *164*, 171 (1967).

section 4.9.6 we shall arrive at the quantization condition (4.28) from a different starting point and calculate very accurate energy levels for the quartic potential $gx^4/4$ by evaluating (4.28) to high orders in \hbar .

Note that the first term $-i\hbar q_1(x)$ in the semiclassical expansion (4.20) of $q(x) = S'(x)$ contributes, via Cauchy's residue theorem, a value $-\pi\hbar$ to the contour integral (4.28). This expansion term can therefore be moved from the left- to the right-hand side of (4.28) by simply changing the right-hand side from $2\pi n\hbar$ to $2\pi(n + \frac{1}{2})\hbar$. This is the origin of the difference between the Bohr-Sommerfeld quantization condition (4.27) and the old the Bohr quantization condition which has only $n\pi$ on the right-hand side of (4.27). Remarkably, the next odd expansion terms $q_3(x)$ is a pure derivative which does not contribute to the contour integral in (4.28) at all. Using all terms up to $q_4(x)$, and applying partial integrations, the quantization condition (4.28) can be re-written as

$$\oint \left\{ (E-V)^{1/2} - \tilde{\hbar}^2 \frac{V'^2}{32(E-V)^{5/2}} - \tilde{\hbar}^4 \frac{49V'^4 - 16(E-V)^2 V'V''''}{2048(E-V)^{11/2}} + \dots \right\} = 2\pi(n + \frac{1}{2})\tilde{\hbar},$$

where $\tilde{\hbar} \equiv \hbar/\sqrt{2M}$. In terms of $\tilde{q}^2(x) \equiv 2Mq^2(x) = E - V(x)$, this becomes

$$\oint \left\{ \tilde{q} - \frac{\tilde{\hbar}^2 (\tilde{q}^2)'^2}{32 \tilde{q}^5} - \frac{\tilde{\hbar}^4}{2048} \left[\frac{49(\tilde{q}^2)^4}{\tilde{q}^{11}} - \frac{16(\tilde{q}^2)'(\tilde{q}^2)''''}{\tilde{q}^7} \right] + \dots \right\} = 2\pi(n + \frac{1}{2})\tilde{\hbar}. \quad (4.29)$$

For the harmonic oscillator, the semiclassical quantization rule (4.27) gives the exact energy levels. Indeed, for an energy E , the classical crossover points with $V(x_E) = E$ are

$$x_c = \pm \sqrt{\frac{2E}{M\omega^2}}, \quad (4.30)$$

to be identified in (4.27) with a and b , respectively. Inserting further

$$k(x) = \frac{p(x)}{\hbar} = \sqrt{\frac{2M}{\hbar^2} \left(E - \frac{1}{2}M\omega^2 x^2 \right)}, \quad (4.31)$$

we obtain the WKB approximation for the energy levels

$$\int_{-x_E}^{x_E} dx' k(x) = \frac{E}{\hbar\omega} \pi = (n + \frac{1}{2})\pi, \quad (4.32)$$

which indeed coincides with the exact ones. Only nonnegative values $n = 0, 1, 2, \dots$ lead to oscillatory waves.

As an example consider the quartic potential $V(x) = gx^4/2$ for which the Schrödinger equation cannot be solved exactly. Inserting this into equation (4.32), we obtain

$$\frac{1}{\hbar} \int_{-x_E}^{x_E} dx \sqrt{2M(E - gx^4/4)} \equiv \nu(E)\pi = (n + \frac{1}{2})\pi, \quad (4.33)$$

with the turning points $\pm x_E = \pm(4E/g)^{1/4}$. The integral is done using the formula⁵

$$\int_0^1 dt t^{\mu-1} (1-t^\lambda)^{\nu-1} = \frac{1}{\lambda} B(\mu/\lambda, \nu) \quad (4.34)$$

which for $\mu = 1$, $\lambda = 4$, and $\nu = 3/2$ yields $(1/4)B(1/4, 3/2)$, so that the left-hand side of Eq.(4.33) can be written with $\Gamma(1/4) = 2\pi/\Gamma(3/4)\sqrt{2}$ as $\nu(E)\pi \equiv E^{3/4}2M^{1/2}\pi^{3/2}/3\hbar g^{1/4}\Gamma^2(3/4)$, and (4.33) determines the energy with principal quantum number n in the Bohr-Sommerfeld approximation by the condition $\nu(E) = n + \frac{1}{2}$ resulting in

$$E_{\text{BS}}^{(n)} = \hbar\omega\kappa_{\text{BS}}^{(n)} \left(\frac{g\hbar}{4M^2\omega^3} \right)^{1/3}, \quad (4.35)$$

with

$$\kappa_{\text{BS}}^{(n)} = \frac{1}{\pi^{2/3}} \left(\frac{3}{2} \right)^{4/3} \Gamma^{8/3}(3/4) (n + \frac{1}{2})^{4/3} \approx 0.688\,253\,702 \times 2(n + \frac{1}{2})^{4/3}. \quad (4.36)$$

This large- n result may be compared with the precise of $\kappa^{(0)} = 0.667986\dots$ to be derived in Section 5.19 (see Table 5.9).

If the potential contains a centrifugal term $V_{\text{cf}}(r) = l(l+1)\hbar^2/2Mr^2$ in addition to the potential $V(\mathbf{x})$, the singularity at $r = 0$ is too strong to apply the WKB approximation. In addition, the factor \hbar^2 in front of this term ruins the systematics of the expansion terms (4.14) if one starts out with $(\nabla S_0)^2 = p^2 = 2M[E - V - l(l+1)\hbar^2/2Mr^2]$. In this situation, the semiclassical treatment needs a modification sketched.

For a rotationally symmetric potential, the wave function in the Schrödinger equation (4.1) can be factorized into a radial part $R(r)/r$ and spherical harmonic $Y_{lm}(\theta, \phi)$ [see (1.420)]. The radial wave function satisfies the radial Schrödinger equation

$$\left\{ -\frac{\hbar^2}{2M}\partial_r^2 - [E - V(r) - V_{\text{cf}}(r)] \right\} R(r) = 0. \quad (4.37)$$

In this equation, one moves the singularity at $r = 0$ to $\xi = -\infty$ by a coordinate transformation $r = e^\xi$, leading to the following nonsingular equation $\chi(\xi) \equiv e^{-\xi/2}R(e^\xi)$:

$$\left[-\frac{\hbar^2}{2M}\partial_\xi^2 - q^2(\xi) \right] \chi(\xi) = 0. \quad (4.38)$$

with

$$\tilde{q}^2(\xi) \equiv e^{2\xi} \left[E - V(e^\xi) - V_{\text{cf}}(e^\xi) - \frac{\hbar^2 e^{-2\xi}}{8M} \right] = e^{2\xi} \left[E - V(e^\xi) - \frac{(l + \frac{1}{2})^2 \hbar^2 e^{-2\xi}}{2M} \right]. \quad (4.39)$$

Inserting this into the quantization condition (4.29), only the first semiclassical term contributes, and all the higher terms vanish, leading to the *exact* energies for the

⁵I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 3.251.1.

Coulomb potential $V(r) = -e^2/r$ with an additional centrifugal barrier $V_{\text{cf}}(x)$. They are the same as the energies obtained from the initial Bohr-Sommerfeld quantization condition (4.27) if we exchange the factor $l(l+1)$ in the centrifugal barrier by $(l+\frac{1}{2})^2$. This exchange is called the *Langer correction*. For a one-dimensional hydrogen atom, the singularity of the Coulomb potential at $r = 0$ is also so strong that one must change the variable r to ξ . Inserting $\tilde{q}^2(\xi) = e^{2\xi} [E + e^2 e^{-\xi} - \frac{1}{8} e^{-2\xi}]$ into the Bohr-Sommerfeld quantization condition (4.27), we obtain the equation, re-expressed in terms of r ,

$$\int_{r_a}^{r_b} (dr/r) \sqrt{2(-1/8 + e^2 r + Er^2)} = \frac{\pi}{2} + \frac{\pi}{\sqrt{-2E}} = (n + \frac{1}{2})\pi,$$

where $r_{a,b}$ are the turning points $r_{a,b} = (e^2 \mp \sqrt{2e^2 + E}) / (-4E)$. For simplicity, we have gone to natural units with $\hbar = 1$, $M = 1$. Thus we find the semiclassical energies $E = -e^4/2n^2$ ($n = 1, 2, 3, \dots$), which are exact. Without the $1/8$ -term from the variable change $r = e^\xi$, the integral would have been equal to $\pi/\sqrt{-2E}$ yielding the approximate energies $E = -e^4/2(n + \frac{1}{2})^2$. These will be derived once more from another semiclassical expansion at the end of Appendix 4A.

4.2 Saddle Point Approximation

Let us now look at the semiclassical expansion within the path integral approach to quantum mechanics. Consider the time evolution amplitude

$$(x_b t_b | x_a t_a) = \int \mathcal{D}x e^{iA[x]/\hbar}, \quad (4.40)$$

imagining Planck's constant \hbar to be again a free parameter which is very small compared to the typical fluctuations of the action. With \hbar appearing in the denominator of an imaginary exponent we see that in the limit $\hbar \rightarrow 0$, the path integral becomes a sum of rapidly oscillating terms which will approximately cancel each other. This phenomenon is known from ordinary integrals

$$\int \frac{dx}{\sqrt{2\pi i \hbar}} e^{ia(x)/\hbar}, \quad (4.41)$$

which converge to zero for $\hbar \rightarrow 0$ according to the Riemann-Lebesgue lemma. The precise behavior is given by the saddle point expansion of integrals which we shall first recapitulate.

4.2.1 Ordinary Integrals

The evaluation of an integral of the type (4.41) proceeds for small \hbar via the so-called *saddle point approximation*. In the limit $\hbar \rightarrow 0$, the integral is dominated by the extremum of the function $a(x)$ with the smallest absolute value, call it x_{cl} (assuming it to be unique, for simplicity), where

$$a'(x_{\text{cl}}) = 0. \quad (4.42)$$

In the path integral, the point x_{cl} in this example corresponds to the classical orbit for which the functional derivative vanishes. This is the reason for using the subscript cl. For x near the extremum, the oscillations of the integrand are weakest. The leading oscillatory behavior of the integral is given by

$$\int_{-\infty}^{\infty} \frac{dx}{\sqrt{2\pi i\hbar}} e^{ia(x)/\hbar} \xrightarrow{\hbar \rightarrow 0} \text{const} \times e^{ia(x_{\text{cl}})/\hbar}, \quad (4.43)$$

with a constant proportionality factor independent of \hbar . This can be calculated by expanding $a(x)$ around its extremum as

$$a(x) = a(x_{\text{cl}}) + \frac{1}{2}a''(x_{\text{cl}})(\delta x)^2 + \frac{1}{3!}a^{(3)}(x_{\text{cl}})(\delta x)^3 + \dots, \quad (4.44)$$

where $\delta x \equiv x - x_{\text{cl}}$ is the deviation from x_{cl} . It is the analog of the *quantum fluctuation* introduced in Section 2.2. Due to (4.42), the linear term in δx is absent. If $a''(x_{\text{cl}}) \neq 0$ and the higher derivatives are neglected, the integral is of the Fresnel type and can be done, yielding

$$\int_{-\infty}^{\infty} \frac{dx}{\sqrt{2\pi i\hbar}} e^{ia(x)/\hbar} \rightarrow e^{ia(x_{\text{cl}})/\hbar} \int_{-\infty}^{\infty} \frac{d\delta x}{\sqrt{2\pi i\hbar}} e^{ia''(x_{\text{cl}})(\delta x)^2/2\hbar} = \frac{e^{ia(x_{\text{cl}})/\hbar}}{\sqrt{a''(x_{\text{cl}})}}. \quad (4.45)$$

The right-hand side is the *saddle point approximation* to the integral (4.41).

The saddle point approximation may be viewed as the consequence of the classical limit of the exponential function:

$$e^{ia(x)/\hbar} \xrightarrow{\hbar \rightarrow 0} \frac{\sqrt{2\pi i\hbar}}{\sqrt{a''(x_{\text{cl}})}} \delta(x - x_{\text{cl}}). \quad (4.46)$$

Corrections can be calculated perturbatively by expanding the integral in powers of \hbar , leading to what is called the *saddle point expansion*. For this we expand the remaining exponent in powers of δx :

$$\begin{aligned} & \exp \left\{ \frac{i}{\hbar} \left[\frac{1}{3!}a^{(3)}(x_{\text{cl}})(\delta x)^3 + \frac{1}{4!}a^{(4)}(x_{\text{cl}})(\delta x)^4 + \dots \right] \right\} \\ &= 1 + \frac{i}{\hbar} \left[\frac{1}{3!}a^{(3)}(x_{\text{cl}})(\delta x)^3 + \frac{1}{4!}a^{(4)}(x_{\text{cl}})(\delta x)^4 + \dots \right] \\ & \quad - \frac{1}{\hbar^2} \left[\frac{1}{72}a^{(3)}(x_{\text{cl}})^2(\delta x)^6 + \dots \right] + \dots \end{aligned} \quad (4.47)$$

and perform the resulting integrals of the type

$$\int_{-\infty}^{\infty} \frac{d\delta x}{\sqrt{2\pi i\hbar}} e^{ia''(x_{\text{cl}})(\delta x)^2/2\hbar} (\delta x)^n = \begin{cases} \frac{(n-1)!!}{[a''(x_{\text{cl}})]^{(1+n)/2}} (i\hbar)^{n/2}, & n = \text{even}, \\ 0, & n = \text{odd}. \end{cases} \quad (4.48)$$

Each factor δx in (4.47) introduces a power $\sqrt{\hbar/a''(x_{\text{cl}})}$. This is the average relative size of the quantum fluctuations. The increasing powers of \hbar ensure the decreasing

importance of the higher terms for small \hbar . For instance, the fourth-order term $a^{(4)}(x_{\text{cl}})(\delta x)^4/4!$ is accompanied by \hbar , and the lowest correction amounts to a factor

$$1 - ia^{(4)}(x_{\text{cl}})\frac{3!!}{4!}\frac{\hbar}{[a''(x_{\text{cl}})]^2}. \quad (4.49)$$

The cubic term $a^{(3)}(x_{\text{cl}})(\delta x)^3/3!$ yields a factor

$$1 + i[a^{(3)}(x_{\text{cl}})]^2\frac{5!!}{72}\frac{\hbar}{[a''(x_{\text{cl}})]^3}. \quad (4.50)$$

Thus we obtain the saddle point expansion to the integral is

$$\int_{-\infty}^{\infty} \frac{dx}{\sqrt{2\pi i\hbar}} e^{ia(x)/\hbar} = \frac{e^{ia(x_{\text{cl}})/\hbar}}{\sqrt{a''(x_{\text{cl}})}} \left\{ 1 - i\hbar \left[\frac{1}{8} \frac{a^{(4)}(x_{\text{cl}})}{[a''(x_{\text{cl}})]^2} - \frac{5}{24} \frac{[a^{(3)}(x_{\text{cl}})]^2}{[a''(x_{\text{cl}})]^3} \right] + \mathcal{O}(\hbar^2) \right\}. \quad (4.51)$$

Expectation values in this integral can also be expanded in powers of \hbar , for instance $\langle x \rangle = x_{\text{cl}} + \langle \delta x \rangle$ where

$$\begin{aligned} \langle \delta x \rangle &= -i\hbar \frac{1}{2} \frac{a^{(3)}(x_{\text{cl}})}{[a''(x_{\text{cl}})]^2} \\ &\quad - \hbar^2 \left[\frac{2}{3} \frac{a^{(3)}(x_{\text{cl}})a^{(4)}(x_{\text{cl}})}{[a''(x_{\text{cl}})]^4} - \frac{5}{8} \frac{[a^{(3)}(x_{\text{cl}})]^3}{[a''(x_{\text{cl}})]^5} - \frac{1}{8} \frac{a^{(5)}(x_{\text{cl}})}{[a''(x_{\text{cl}})]^3} \right] + \mathcal{O}(\hbar^3). \end{aligned} \quad (4.52)$$

Since the saddle point expansion is organized in powers of \hbar , it corresponds precisely to the semiclassical expansion of the eikonal in the previous section.

The saddle point expansion can be used for very small \hbar to calculate an integral with increasing accuracy. It is impossible, however, to achieve arbitrary accuracy since the resulting series is divergent for all physically interesting systems. It is merely an *asymptotic series* whose usefulness decreases rapidly with an increasing size of the expansion parameter. A variational expansion must be used to achieve convergence. For more details, see Sections 5.15 and 17.9.

An important property of the semiclassical approximation is that Fourier transformations become very simple. Consider the Fourier integral

$$\int_{-\infty}^{\infty} dx e^{-ipx/\hbar} e^{ia(x)/\hbar}. \quad (4.53)$$

For small \hbar , this can be done in the saddle point approximation according to the rule (4.46), and obtain

$$\int_{-\infty}^{\infty} dx e^{-ipx/\hbar} e^{ia(x)/\hbar} \rightarrow \sqrt{2\pi i\hbar} \frac{e^{i[a(x_{\text{cl}})-px_{\text{cl}}]/\hbar}}{\sqrt{a''(x_{\text{cl}})}}, \quad (4.54)$$

where x_{cl} is now the extremum of the action with a source term p , i.e., it is determined by the equation $p = a'(x_{\text{cl}})$. Note that the formula holds also if the exponential carries an x -dependent prefactor, since the x -dependence gives only corrections of the order of \hbar in the exponent:

$$\int_{-\infty}^{\infty} dx e^{-ipx/\hbar} c(x) e^{ia(x)/\hbar} \rightarrow \sqrt{2\pi i\hbar} c(x_{\text{cl}}) \frac{e^{i[a(x_{\text{cl}})-px_{\text{cl}}]/\hbar}}{\sqrt{a''(x_{\text{cl}})}}. \quad (4.55)$$

If the equation $p = a'(x_{\text{cl}})$ is inverted to find x_{cl} as a function $x_{\text{cl}}(p)$, the exponent $a(x_{\text{cl}}) - px_{\text{cl}}$ may be considered as a function of p :

$$b(p) = a(x_{\text{cl}}) - px_{\text{cl}}, \quad p = a'(x_{\text{cl}}). \quad (4.56)$$

This function is recognized as being the Legendre transform of the function $a(x)$ [recall (1.9)].

The original function $a(x)$ can be recovered from $b(p)$ via an inverse Legendre transformation

$$a(x) = b(p_{\text{cl}}) + xp_{\text{cl}}, \quad x = -b'(p_{\text{cl}}). \quad (4.57)$$

This formalism is the basis for many thermodynamic calculations. For large statistical systems, fluctuations of global properties such as the volume and the total internal energy are very small so that the saddle point approximation is very good. In this chapter, the formalism will be applied on many occasions.

4.2.2 Path Integrals

A similar saddle point expansion exists for the path integral (4.40). For small \hbar , the amplitudes $e^{iA/\hbar}$ from the various paths will mostly cancel each other by interference. The dominant contribution comes from the functional regime where the oscillations are weakest, which is from extremum of the action

$$\delta\mathcal{A}[x] = 0. \quad (4.58)$$

This gives the classical Euler-Lagrange equation of motion. For a point particle with the action

$$\mathcal{A}[x] = \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{x}^2 - V(x) \right], \quad (4.59)$$

it reads

$$M\ddot{x} = -V'(x). \quad (4.60)$$

Let $x_{\text{cl}}(t)$ denote the classical orbit. After multiplying (4.60) by \dot{x} , an integration in t yields the law of energy conservation

$$E = \frac{M}{2} \dot{x}_{\text{cl}}^2 + V(x_{\text{cl}}) = \text{const}. \quad (4.61)$$

This implies that the classical momentum

$$p_{\text{cl}}(t) \equiv M\dot{x}_{\text{cl}}(t) \quad (4.62)$$

can be written as

$$p_{\text{cl}}(t) = p(x_{\text{cl}}(t)), \quad (4.63)$$

where $p(x)$ is the local classical momentum defined in (4.3). From (4.61), the time dependence of the classical orbit $x_{\text{cl}}(t)$ is given by

$$t - t_0 = \int_0^{x_{\text{cl}}} dx \frac{M}{p(x)} = \int_0^{x_{\text{cl}}} dx \frac{M}{\sqrt{2M[E - V(x)]}}. \quad (4.64)$$

When solving the integral on the right-hand side we find for a given time interval $t = t_b - t_a$ the energy for which a pair of positions x_a, x_b can be connected by a classical orbit:

$$E = E(x_b, x_a; t_b - t_a). \quad (4.65)$$

The classical action is given by

$$\begin{aligned} \mathcal{A}[x_{\text{cl}}] &= \int_{t_a}^{t_b} dt \left[\frac{M}{2} \dot{x}_{\text{cl}}^2 - V(x_{\text{cl}}) \right] \\ &= \int_{t_a}^{t_b} dt [p_{\text{cl}}(t) \dot{x}_{\text{cl}} - H(p_{\text{cl}}, x_{\text{cl}})] \\ &= \int_{x_a}^{x_b} dx p(x) - (t_b - t_a)E. \end{aligned} \quad (4.66)$$

Just like E , the classical action is a function of x_b, x_a and $t_b - t_a$, to be denoted by $A(x_b, x_a; t_b - t_a)$, for which (4.66) reads more explicitly

$$A(x_b, x_a; t_b - t_a) \equiv \int_{x_a}^{x_b} dx p(x) - (t_b - t_a)E(x_b, x_a; t_b - t_a). \quad (4.67)$$

Recalling (4.11), the first term on the right-hand side is seen to be the classical eikonal

$$S(x_b, x_a; E) = \int_{x_a}^{x_b} dx p(x), \quad (4.68)$$

where E is the energy function (4.65) and $p(x)$ is given by (4.3),

The eikonal may be viewed as a functional $S_E[x]$ of paths $x(t)$ of a fixed energy, in which case it is extremal on the classical orbits. This was observed as early as 1744 by Maupertius [2]. The proof for this is quite simple: We insert the classical momentum (4.3) into $S_E[x]$ and write

$$S_E[x] \equiv \int p(x) dx = \int dt p(x) \dot{x} = \int dt L_E(x, \dot{x}) = \int dt \sqrt{2M[E - V(x)]} \dot{x}, \quad (4.69)$$

thus introducing a Lagrangian $L_E(x, \dot{x})$ for this problem. The associated Euler-Lagrange equation reads

$$\frac{d}{dt} \frac{\partial L_E}{\partial \dot{x}} = \frac{\partial L_E}{\partial x}. \quad (4.70)$$

Inserting $L_E(x, \dot{x}) = p(x) \dot{x}$ we find the correct equation of motion $\dot{p} = -V'(x)$.

There is an interesting geometrical aspect to this variational procedure. In order to see this let us go to D dimensions and write the eikonal (4.69) as

$$S_E[\mathbf{x}] = \int dt L_E(\mathbf{x}, \dot{\mathbf{x}}) = \int dt \sqrt{g_{ij}(\mathbf{x}) \dot{x}^i(t) \dot{x}^j(t)}, \quad (4.71)$$

with an energy-dependent metric

$$g_{ij}(\mathbf{x}) = p_E^2(\mathbf{x}) \delta_{ij}. \quad (4.72)$$

Then the Euler-Lagrange equations for $\mathbf{x}(t)$ coincides with the equation (1.72) for the geodesics in a Riemannian space with a metric $g_{ij}(\mathbf{x})$. In this way, the dynamical problem has been reduced to a geometric problem. The metric $g_{ij}(\mathbf{x})$ may be called *dynamical metric* of the space with respect to the potential $V(\mathbf{x})$. This geometric view is further enhanced by the fact that the eikonal (4.69) is, in fact, independent of the parametrization of the trajectory. Instead of the time t we could have used any parameter τ to describe $\mathbf{x}(\tau)$ and write the eikonal (4.69) as

$$S_E[\mathbf{x}] = \int d\tau \sqrt{g_{ij}(\mathbf{x}) \dot{x}^i(\tau) \dot{x}^j(\tau)}. \quad (4.73)$$

Einstein has certainly been inspired by this ancient description of classical trajectories when geometrizing the relativistic Kepler motion by attributing a dynamical Riemannian geometry to spacetime.

It is worth pointing out a subtlety in this variational principle, in view of a closely related situation to be encountered later in Chapter 10. The variations are supposed to be carried out at a fixed energy

$$E = \frac{M}{2} \dot{\mathbf{x}}^2 + V(\mathbf{x}). \quad (4.74)$$

This is a nonholonomic constraint which destroys the independence of the variation $\delta x(t)$ and $\delta \dot{x}$. They are related by

$$\dot{\mathbf{x}} \delta \dot{\mathbf{x}} = -\frac{1}{M} \nabla V(\mathbf{x}) \delta \mathbf{x}. \quad (4.75)$$

It is, however, possible to regain the independence by allowing for a simultaneous variation of the time argument in $\mathbf{x}(t)$ when varying $\mathbf{x}(\mathbf{t})$. As a consequence, we can no longer employ the standard equality $\delta \dot{x} = d\delta x/dt$ which is necessary for the derivation of the Euler-Lagrange equation (4.70). Instead, we calculate

$$\delta \dot{\mathbf{x}} = \frac{d\mathbf{x} + d\delta \mathbf{x}}{dt + d\delta t} - \dot{\mathbf{x}} = \frac{d}{dt} \delta \mathbf{x} - \dot{\mathbf{x}} \frac{d}{dt} \delta t, \quad (4.76)$$

which shows that variation and time derivatives no longer commute with each other. Combining this with the relation (4.75) we see that the variations of \mathbf{x} and $\dot{\mathbf{x}}$ can be made independent if we vary t along the orbit according to the relation

$$\dot{\mathbf{x}}^2 \frac{d}{dt} \delta t = \dot{\mathbf{x}} \frac{d}{dt} \delta \mathbf{x} + \frac{1}{M} \nabla V(\mathbf{x}) \delta \mathbf{x}. \quad (4.77)$$

With (4.76), the variations of the eikonal (4.71) are

$$\delta S_E[\mathbf{x}] = \int dt \left(\frac{\partial L_E}{\partial \dot{\mathbf{x}}} \frac{d}{dt} \delta \mathbf{x} + \frac{\partial L_E}{\partial \mathbf{x}} \delta \mathbf{x} \right) + \int dt \left(L_E - \frac{\partial L_E}{\partial \dot{\mathbf{x}}} \dot{\mathbf{x}} \right) \frac{d}{dt} \delta t, \quad (4.78)$$

where we have kept the usual commutativity of variation and time derivative of the time itself. In the second integral, we may set

$$-L_E + \frac{\partial L_E}{\partial \dot{\mathbf{x}}} \dot{\mathbf{x}} \equiv H_E. \quad (4.79)$$

The function H_E arises from L_E by the same combination of $L_E(\mathbf{x}, \dot{\mathbf{x}})$ and $\partial L_E / \partial \dot{\mathbf{x}}(\mathbf{x}, \dot{\mathbf{x}})$ as in a Legendre transformation which brings a Lagrangian to the associated Hamiltonian [recall (1.13)]. But in contrast to the usual procedure we do not eliminate $\dot{\mathbf{x}}$ in favor of a canonical momentum variable $\partial L_E / \partial \dot{\mathbf{x}}$ [recall (1.14)], i.e., the H_E is a function $H_E(\mathbf{x}, \dot{\mathbf{x}})$. Note that it is *not* equal to the energy.

The variation (4.78) shows that the extra variation δt of the time does not change the Euler-Lagrange equations for the above Lagrangian in Eq. (4.71), $L_E = \sqrt{2M[E - V(\mathbf{x})]}\dot{\mathbf{x}}^2$. Being linear in $\dot{\mathbf{x}}$, the associated H_E vanishes identically, so that the second term disappears and we recover the ordinary equation of motion

$$\frac{d}{dt} \frac{\partial L_E}{\partial \dot{\mathbf{x}}} = \frac{\partial L_E}{\partial \mathbf{x}}. \quad (4.80)$$

In general, however, we must keep the second term. Expressing $d\delta t/dt$ via (4.77), we find

$$\begin{aligned} \delta S_E[\mathbf{x}] &= \int dt \left[\frac{\partial L_E}{\partial \dot{\mathbf{x}}} - H_E \frac{\dot{\mathbf{x}}}{\dot{\mathbf{x}}^2} \right] \frac{d}{dt} \delta \mathbf{x} \\ &+ \int dt \left[\frac{\partial L_E}{\partial \mathbf{x}} - H_E \frac{1}{\dot{\mathbf{x}}^2} \frac{1}{M} \nabla V(\mathbf{x}) \right] \delta \mathbf{x}, \end{aligned} \quad (4.81)$$

and the general equation of motion becomes

$$\frac{d}{dt} \left[\frac{\partial L_E}{\partial \dot{\mathbf{x}}} - H_E \frac{\dot{\mathbf{x}}}{\dot{\mathbf{x}}^2} \right] = \frac{\partial L_E}{\partial \mathbf{x}} - H_E \frac{1}{\dot{\mathbf{x}}^2} \frac{1}{M} \nabla V(\mathbf{x}), \quad (4.82)$$

rather than (4.80). Let us illustrate this by rewriting the eikonal as a functional

$$S_E[\mathbf{x}] = \int dt L'_E(\mathbf{x}, \dot{\mathbf{x}}) = M \int dt \dot{\mathbf{x}}^2(t), \quad (4.83)$$

which is the same functional as (4.69) as long as the energy E is kept fixed. If we insert the new Lagrangian L'_E into (4.82), we obtain the correct equation of motion

$$M\ddot{\mathbf{x}} = -\nabla V(\mathbf{x}). \quad (4.84)$$

In this case, the equation of motion can actually be found more directly. We vary the eikonal (4.83) as follows:

$$\delta S_E[\mathbf{x}] = M \int \delta dt \dot{\mathbf{x}}^2 + M \int dt \dot{\mathbf{x}} \delta \dot{\mathbf{x}} + M \int dt \dot{\mathbf{x}} \delta \dot{\mathbf{x}}. \quad (4.85)$$

In the last term we insert the relation (4.76) and write

$$\delta S_E[\mathbf{x}] = M \left[\int \delta dt \dot{\mathbf{x}}^2 + \int dt \dot{\mathbf{x}} \delta \dot{\mathbf{x}} + \int dt \dot{\mathbf{x}} \frac{d}{dt} \delta \mathbf{x} - \int dt \dot{\mathbf{x}}^2 \frac{d}{dt} \delta t \right]. \quad (4.86)$$

The two terms containing δt cancel each other, so that relation (4.77) is no longer needed. Using now (4.75), we obtain directly the equation of motion (4.84).

With the help of the eikonal (4.68), we write the classical action (4.66) as

$$A(x_b, x_a; t_b - t_a) \equiv S(x_b, x_a; E) - (t_b - t_a)E, \quad (4.87)$$

where E is given by (4.65).

The action has the property that its derivatives with respect to the endpoints x_b, x_a at a fixed $t_b - t_a$ yield the initial and final classical momenta:

$$\frac{\partial}{\partial x_{b,a}} A(x_b, x_a; t_b - t_a) = \pm p(x_{b,a}). \quad (4.88)$$

Indeed, the differentiation gives

$$\frac{\partial A}{\partial x_b} = p(x_b) + \left[\int_{x_a}^{x_b} dx \frac{\partial p(x)}{\partial E} - (t_b - t_a) \right] \frac{\partial E}{\partial x_b}, \quad (4.89)$$

and using

$$\frac{\partial p(x)}{\partial E} = \frac{M}{p(x)} = \frac{1}{\dot{x}}, \quad (4.90)$$

we see that

$$\int_{x_a}^{x_b} dx \frac{\partial p(x)}{\partial E} = \int_{t_a}^{t_b} dt = t_b - t_a, \quad (4.91)$$

so that the bracket in (4.89) vanishes, and (4.88) is indeed fulfilled [compare also (4.12)]. The relation (4.91) implies that the eikonal (4.68) has the energy derivative

$$\frac{\partial}{\partial E} S(x_b, x_a; E) = t_b - t_a. \quad (4.92)$$

As a conjugate relation, the derivative of the action with respect to the time t_b at fixed x_b gives the energy with a minus sign [compare (4.10)]:

$$\frac{\partial}{\partial t_b} A(x_b, x_a; t_b - t_a) = -E(x_b, x_a; t_b - t_a). \quad (4.93)$$

This is easily verified:

$$\frac{\partial}{\partial t_b} A = \left[\int_{x_a}^{x_b} dx \frac{\partial p}{\partial E} - (t_b - t_a) \right] \frac{\partial E}{\partial t_b} - E = -E. \quad (4.94)$$

Thus, the classical action function $A(x_b, x_a; t_b - t_a)$ and the eikonal $S(x_b, x_a; E)$ are Legendre transforms of each other.

The equation

$$\frac{1}{2M} (\partial_x A)^2 + V(x) = \partial_t A \quad (4.95)$$

is, of course, the Hamilton-Jacobi equation (4.13) of classical mechanics.

We have therefore found the leading term in the semiclassical approximation to the amplitude [corresponding to the approximation (4.43)]:

$$(x_b t_b | x_a t_a) \xrightarrow{\hbar \rightarrow 0} \text{const} \times e^{iA(x_b, x_a; t_b - t_a)/\hbar}. \quad (4.96)$$

In general, this leading term will be multiplied by a fluctuation factor

$$(x_b t_b | x_a t_a) = e^{iA(x_b, x_a; t_b - t_a)/\hbar} F(x_b, x_a; t_b - t_a). \quad (4.97)$$

In contrast to the purely harmonic case in Eq. (2.153) this will depend on the initial and final coordinates x_a and x_b .

The calculation of the leading contribution to the fluctuation factor is the next step in the saddle point expansion of the path integral (4.40). For this we expand the action (4.59) in the neighborhood of the classical orbit in powers of the fluctuations

$$\delta x(t) = x(t) - x_{cl}(t). \quad (4.98)$$

This yields the fluctuation expansion

$$\begin{aligned} \mathcal{A}[x, \dot{x}] &= \mathcal{A}[x_{cl}] + \int_{t_a}^{t_b} dt \frac{\delta \mathcal{A}}{\delta x(t)} \delta x(t) \\ &+ \frac{1}{2} \int_{t_a}^{t_b} dt dt' \frac{\delta^2 \mathcal{A}}{\delta x(t) \delta x(t')} \delta x(t) \delta x(t') \\ &+ \frac{1}{3!} \int_{t_a}^{t_b} dt dt' dt'' \frac{\delta^3 \mathcal{A}}{\delta x(t) \delta x(t') \delta x(t'')} \delta x(t) \delta x(t') \delta x(t'') + \dots, \end{aligned} \quad (4.99)$$

where all functional derivatives on the right-hand side are evaluated along the classical orbit $x(t) = x_{cl}(t)$. The linear term in the quantum fluctuation $\delta x(t)$ is absent since $\mathcal{A}[x, \dot{x}]$ is extremal at $x_{cl}(t)$. For a point particle, the quadratic term is

$$\frac{1}{2} \int_{t_a}^{t_b} dt dt' \frac{\delta^2 \mathcal{A}}{\delta x(t) \delta x(t')} \delta x(t) \delta x(t') = \int_{t_a}^{t_b} dt \left[\frac{M}{2} (\delta \dot{x})^2 + \frac{1}{2} V''(x_{cl}(t)) (\delta x)^2 \right]. \quad (4.100)$$

Thus the fluctuations behave like those of a harmonic oscillator with a time-dependent frequency

$$\Omega^2(t) = \frac{1}{M} V''(x_{cl}(t)). \quad (4.101)$$

By definition, the fluctuations vanish at the endpoints:

$$\delta x(t_a) = 0, \quad \delta x(t_b) = 0. \quad (4.102)$$

If we include only the quadratic terms in the fluctuation expansion (4.99), we can integrate out the fluctuations in the path integral (4.40). Since $x(t)$ and $\delta x(t)$

differ only by a fixed additive function $x_{\text{cl}}(t)$, the measure of the path integral over $x(t)$ transforms trivially into that over $\delta x(t)$. Thus we conclude that the leading semiclassical limit of the amplitude is given by the product

$$(x_b t_b | x_a t_a)_{\text{sc}} = e^{iA(x_b, x_a; t_b - t_a)/\hbar} F_{\text{sc}}(x_b, x_a; t_b - t_a), \quad (4.103)$$

with the semiclassical fluctuation factor [compare (2.200)]

$$\begin{aligned} F_{\text{sc}}(x_b, x_a; t_b - t_a) &= \int \mathcal{D}\delta x(t) \exp \left\{ \frac{i}{\hbar} \int_{t_b}^{t_a} dt \frac{M}{2} [\dot{\delta x}^2 - \Omega^2(t) \delta x^2] \right\} \\ &= \frac{1}{\sqrt{2\pi i \epsilon \hbar / M}} \det(-\bar{\nabla} \nabla - \Omega^2(t))^{-1/2} \\ &= \frac{1}{\sqrt{2\pi i \hbar (t_b - t_a) / M}} \sqrt{\frac{\det(-\partial_t^2)}{\det(-\partial_t^2 - \Omega^2(t))}}. \end{aligned} \quad (4.104)$$

In principle, we would now have to solve the differential equation

$$[-\partial_t^2 - \Omega^2(t)]y_n(t) = [-\partial_t^2 - V''(x_{\text{cl}}(t))/M]y_n(t) = \lambda_n y_n(t), \quad (4.105)$$

and find the energies of the eigenmodes $y_n(t)$ of the fluctuations. The ratio of fluctuation determinants

$$\frac{D^0}{D} = \frac{\det(-\partial_t^2)}{\det(-\partial_t^2 - \Omega^2(t))} \quad (4.106)$$

in the second line of (4.104) would then be found from the product of ratios of eigenvalues, λ_n/λ_n^0 , where λ_n^0 are the eigenvalues of the differential equation

$$-\partial_t^2 y_n(t) = \lambda_n^0 y_n(t). \quad (4.107)$$

Fortunately, we can save ourselves all this work using the Gelfand-Yaglom method of Section 2.4 which provides a much simpler and more direct way of calculating fluctuation determinants with a time-dependent frequency without the knowledge of the eigenvalues λ_n .

4.3 Van Vleck-Pauli-Morette Determinant

According to the Gelfand-Yaglom method of Section 2.4, a functional determinant of the form

$$\det(-\partial_t^2 - \Omega^2(t))$$

is found by solving the differential equation (4.105) at zero eigenvalue

$$[-\partial_t^2 - \Omega^2(t)]D_a(t) = 0,$$

with the initial conditions

$$D_a(t_a) = 0, \quad \dot{D}_a(t_a) = 1. \quad (4.108)$$

Then $D_a(t_b)$ is the desired fluctuation determinant. In Eq. (2.240), we have constructed the solution to these equations in terms of an arbitrary solution $\xi(t)$ of the homogenous equation

$$[-\partial_t^2 - \Omega^2(t)]\xi(t) = 0 \quad (4.109)$$

as

$$D_{\text{ren}} = \xi(t)\xi(t_a) \int_{t_a}^{t_b} \frac{dt'}{\xi^2(t')}. \quad (4.110)$$

In general, it is difficult to find an analytic solution to Eq. (4.109). In the present fluctuation problem, however, the time-dependent frequency $\Omega(t)$ has a special form $\Omega^2(t) = V''(x_{\text{cl}}(t))/M$ of (4.101). We shall now prove that, just as in the purely harmonic action in Section 2.5, all information on the fluctuation determinant is contained in the classical orbit $x_{\text{cl}}(t)$, and ultimately in the mixed spatial derivatives $\partial_{x_b}\partial_{x_a}$ of the classical action $A(x_b, x_a; t_b - t_a)$. In fact, the solution $\xi(t)$ is simply equal to the velocity

$$\xi(t) = \dot{x}_{\text{cl}}(t). \quad (4.111)$$

This is seen directly by differentiating the equation of motion (4.60) with respect to t , yielding

$$\partial_t[M\ddot{x}_{\text{cl}} + V'(x_{\text{cl}}(t))] = [M\partial_t^2 + V''(x_{\text{cl}}(t))]\dot{x}_{\text{cl}}(t) = 0, \quad (4.112)$$

which is precisely the homogenous differential equation (4.109) for $\dot{x}_{\text{cl}}(t)$.

There is a simple symmetry argument to understand (4.111) as a completely general consequence of the time translation invariance of the system. The fluctuation $\delta x(t) \propto \dot{x}_{\text{cl}}(t)$ describes an infinitesimal translation of the classical solution $x_{\text{cl}}(t)$ in time, $x_{\text{cl}}(t) \rightarrow x_{\text{cl}}(t + \epsilon) = x_{\text{cl}} + \epsilon\dot{x}_{\text{cl}} + \dots$. Interpreted as a *translational fluctuation* of the solution $x_{\text{cl}}(t)$ along the time axis it cannot carry any energy λ_n and $y_0(t) \propto \dot{x}_{\text{cl}}(t)$ must therefore solve Eq. (4.105) with $\lambda_0 = 0$.

With the special solution (4.111), the functional determinant (4.110) becomes

$$D_{\text{ren}} = \dot{x}_{\text{cl}}(t_b)\dot{x}_{\text{cl}}(t_a) \int_{t_a}^{t_b} \frac{dt}{\dot{x}_{\text{cl}}^2(t)}. \quad (4.113)$$

Note that also the Green-function of the quadratic fluctuations associated with Eq. (4.109) can be given explicitly in terms of the classical solution $x_{\text{cl}}(t)$. For Dirichlet boundary conditions, it is equal to the combination (3.61) of the solutions $D_a(t)$ and $D_b(t)$ of the homogeneous differential equation (4.109) satisfying the boundary conditions (2.228) and (2.229), whose d'Alembert construction (2.239) becomes here

$$D_a(t) = \dot{x}_{\text{cl}}(t)\dot{x}_{\text{cl}}(t_a) \int_{t_a}^t \frac{dt}{\dot{x}_{\text{cl}}^2(t)}, \quad D_b(t) = \dot{x}_{\text{cl}}(t_b)\dot{x}_{\text{cl}}(t) \int_t^{t_b} \frac{dt}{\dot{x}_{\text{cl}}^2(t)}. \quad (4.114)$$

In Eqs. (2.252) and (2.269) we have found two simple expressions for the fluctuation determinant in terms of the classical action

$$D_{\text{ren}} = - \left(\frac{\partial \dot{x}_b}{\partial x_a} \right)^{-1} = -M \left[\frac{\partial^2}{\partial x_b \partial x_a} \mathcal{A}_{\text{cl}} \right]^{-1}. \quad (4.115)$$

These were derived for purely quadratic actions with an arbitrary time-dependent frequency $\Omega^2(t)$. But they hold for any action. First, the equality between the second and third expression is a consequence of the general relation (4.88). Second, we may consider the semiclassical approximation to the path integral as an *exact* path integral associated with the lowest quadratic approximation to the action in (4.99), (4.100):

$$\mathcal{A}_{\text{qu}}[x, \dot{x}] = \mathcal{A}[x_{\text{cl}}] + \int_{t_a}^{t_b} dt \left[\frac{M}{2} (\delta \dot{x})^2 + \Omega^2(t) (\delta x)^2 \right], \quad (4.116)$$

with $\Omega^2(t) = V''(x_{\text{cl}}(t))/M$ of (4.101). Then, since the classical orbit running from x_a to x_b satisfies the equation of motion (4.112), also a slightly different orbit $(x_{\text{cl}} + \delta x_{\text{cl}})(t)$ from $x'_a = x_a + \delta x_a$ to $x'_b = x_b + \delta x_b$ satisfies (4.112). Although the small change of the classical orbit gives rise to a slightly different frequency $\Omega^2(t) = V''((x_{\text{cl}} + \delta x_{\text{cl}})(t))/M$, this contributes only to second order in δx_a and δx_b . As a consequence, the derivative $D_a(t) = -\partial \dot{x}_b(t)/\partial x_a$ satisfies Eq. (4.112) as well. Also the boundary conditions of $D_a(t)$ are the same as those of $D_a(t)$ in Eqs. (2.228). Hence the quantity $D_a(t_b)$ is the correct fluctuation determinant also for the general action in the semiclassical approximation under study.

Another way to derive this formula makes use of the general relation (4.88), from which we find

$$\frac{\partial}{\partial x_b} \frac{\partial}{\partial x_a} A(x_b, x_a; t_b - t_a) = \frac{\partial}{\partial x_a} p(x_b) = \frac{M}{p(x_b)} \frac{\partial E}{\partial x_a}. \quad (4.117)$$

On the right-hand side we have suppressed the arguments of the function $E(x_b, x_a; t_b - t_a)$. After rewriting

$$\begin{aligned} \frac{\partial E}{\partial x_a} &= -\frac{\partial}{\partial x_a} \frac{\partial A}{\partial t_b} = -\frac{\partial}{\partial t_b} \frac{\partial A}{\partial x_a} \\ &= \frac{\partial}{\partial t_b} p(x_a) = \frac{M}{p(x_a)} \frac{\partial E}{\partial t_b}, \end{aligned} \quad (4.118)$$

we see that

$$\frac{\partial}{\partial x_b} \frac{\partial}{\partial x_a} A(x_b, x_a; t_b - t_a) = \frac{1}{\dot{x}(t_b) \dot{x}(t_a)} \frac{\partial E}{\partial t_b}. \quad (4.119)$$

From (4.64) we calculate

$$\begin{aligned} \frac{\partial E}{\partial t_b} &= \left(\frac{\partial t_b}{\partial E} \right)^{-1} = \left[-\int_{x_a}^{x_b} dx \frac{M}{p^2} \frac{\partial p}{\partial E} \right]^{-1} \\ &= \left[-\int_{x_a}^{x_b} dx \frac{M^2}{p^3} \right]^{-1} = \left[-M \int_{t_a}^{t_b} dt \frac{dt}{p^2} \right]^{-1} = \left[-\frac{1}{M} \int_{t_a}^{t_b} dt \frac{dt}{\dot{x}_{\text{cl}}^2(t)} \right]^{-1}. \end{aligned} \quad (4.120)$$

Inserting this into (4.119), we obtain once more formula (4.115) for the fluctuation determinant.

A relation following from (4.92):

$$\frac{\partial E}{\partial t_b} = \left(\frac{\partial^2 S}{\partial E^2} \right)^{-1}, \quad (4.121)$$

leads to an alternative expression

$$D_{\text{ren}} = -M \dot{x}_{\text{cl}}(t_b) \dot{x}_{\text{cl}}(t_a) \frac{\partial^2 S}{\partial E^2}. \quad (4.122)$$

The fluctuation factor is therefore also here [recall the normalization from Eqs. (2.202), (2.204), and (2.212)]

$$F(x_b, t_a; t_b - t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \left[\frac{\partial \dot{x}_b}{\partial x_a} \right]^{1/2} = \frac{1}{\sqrt{2\pi i \hbar}} [-\partial_{x_b} \partial_{x_a} A(x_b, x_a; t_b - t_a)]^{1/2}. \quad (4.123)$$

Its D -dimensional generalization of (4.123) is

$$F(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a) = \frac{1}{\sqrt{2\pi i \hbar}^D} \left\{ \det_D [-\partial_{x_b^i} \partial_{x_a^j} A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)] \right\}^{1/2}, \quad (4.124)$$

and the semiclassical time evolution amplitude reads

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \frac{1}{\sqrt{2\pi i \hbar}^D} \left\{ \det_D [-\partial_{x_b^i} \partial_{x_a^j} A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)] \right\}^{1/2} e^{iA(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)/\hbar}. \quad (4.125)$$

The $D \times D$ -determinant in the curly brackets is the so-called *Van Vleck-Pauli-Morette determinant*.⁶ It is the analog of the determinant in the right-hand part of Eq. (2.270). As discussed there, the result is initially valid only as long as the fluctuation determinant is regular. Otherwise we must replace the determinant by its absolute value, and multiply the fluctuation factor by the phase factor $e^{-i\nu/2}$ with the Maslov-Morse index ν [see Eq. (2.271)]. Using the relation (4.88) in D dimensions

$$\partial_{x_b^i} \partial_{x_a^j} A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a) = \frac{\partial p_b^i}{\partial x_a^j}, \quad (4.126)$$

we shall often write (4.125) as

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \frac{1}{\sqrt{2\pi i \hbar}^D} \left[\det_D \left(-\frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \right) \right]^{1/2} e^{iA(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)/\hbar}, \quad (4.127)$$

where the subscripts a and b can be interchanged in the determinant, if the sign is changed [recall (2.252)]. This concludes the calculation of the semiclassical approximation to the time evolution amplitude.

⁶J.H. Van Vleck, Proc. Nat. Acad. Sci. (USA) 14, 178 (1928); W. Pauli, *Selected Topics in Field Quantization*, MIT Press, Cambridge, Mass. (1973); C. DeWitt-Morette, Phys. Rev. 81, 848 (1951).

As a simple application, we use this formula to write down the semiclassical amplitude for a free particle and a harmonic oscillator. The first has the classical action

$$A(x_b, x_a; t_b - t_a) = \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a}, \quad (4.128)$$

and Eq. (4.115) gives

$$D_{\text{ren}} = t_b - t_a, \quad (4.129)$$

as it should. The harmonic-oscillator action is

$$A(x_b, x_a; t_b - t_a) = \frac{M\omega}{2 \sin \omega(t_b - t_a)} \left[(x_b^2 + x_a^2) \cos \omega(t_b - t_a) - 2x_b x_a \right], \quad (4.130)$$

and has the second derivative

$$-\partial_{x_b} \partial_{x_a} A = \frac{M\omega}{\sin \omega(t_b - t_a)}, \quad (4.131)$$

so that (4.123) coincides with fluctuation factor (2.216).

4.4 Fundamental Composition Law for Semiclassical Time Evolution Amplitude

The determinant ensures that the semiclassical approximation for the time evolution amplitude satisfies the fundamental composition law (2.4) in D dimensions

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \prod_{n=1}^N \left[\int_{-\infty}^{\infty} d^D x_n \right] \prod_{n=1}^{N+1} (\mathbf{x}_n t_n | \mathbf{x}_{n-1} t_{n-1}), \quad (4.132)$$

if the intermediate \mathbf{x} -integrals are evaluated in the saddle point approximation. To leading order in \hbar , only those intermediate \mathbf{x} -values contribute which lie on the classical trajectory determined by the endpoints of the combined amplitude. To next order in \hbar , the quadratic correction to the intermediate integrals renders an inverse square root of the fluctuation determinant. If two such amplitudes are connected with each other by an intermediate integration according to the composition law (4.132), the product of the two fluctuation factors turns into the correct fluctuation factor of the combined time interval. This is seen after rewriting the matrix $\partial_{x_b^i} \partial_{x_a^j} A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)$ with the help of (4.12) as $\partial \mathbf{p}_b / \partial \mathbf{x}_a$. The intermediate integral over \mathbf{x} in the product of two amplitudes receives a contribution only from continuous paths since, at the saddle point, the adjacent momenta have to be equal:

$$\frac{\partial}{\partial \mathbf{x}} A(\mathbf{x}_b, \mathbf{x}; t_b - t) + \frac{\partial}{\partial \mathbf{x}} A(\mathbf{x}, \mathbf{x}_a; t - t_a) = -\mathbf{p}'(\mathbf{x}_b, \mathbf{x}; t_b - t) + \mathbf{p}(\mathbf{x}, \mathbf{x}_a; t - t_a) = 0. \quad (4.133)$$

To obtain the combined amplitude, we obviously need the relation

$$\det_D \left(- \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} \right) \left\{ \det_D \left(- \frac{\partial \mathbf{p}'}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} + \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \Big|_{\mathbf{x}_a} \right)_{\mathbf{p}'=\mathbf{p}} \right\}^{-1} \det_D \left(- \frac{\partial \mathbf{p}}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}} \right) \\ = \det_D \left(- \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}_b} \right), \quad (4.134)$$

where we have indicated explicitly the variables kept fixed in $\mathbf{p}'(\mathbf{x}_b, \mathbf{x}; t_b - t)$ and $\mathbf{p}(\mathbf{x}, \mathbf{x}_a; t - t_a)$ when forming the partial derivatives. To prove (4.134), we use the product rule for determinants

$$\det_D^{-1} \left(- \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} \right) \det_D \left(- \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}_b} \right) = \det_D \left(\frac{\partial \mathbf{x}}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}_b} \right) \quad (4.135)$$

to rewrite (4.134) as

$$\det_D \left(- \frac{\partial \mathbf{p}}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}} \right) = \det_D \left(- \frac{\partial \mathbf{p}'}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} + \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \Big|_{\mathbf{x}_a} \right)_{\mathbf{p}'=\mathbf{p}} \det_D \left(\frac{\partial \mathbf{x}}{\partial \mathbf{x}_a} \Big|_{\mathbf{x}_b} \right). \quad (4.136)$$

This equation is true due to the chain rule of differentiation applied to the momentum $\mathbf{p}'(\mathbf{x}_b, \mathbf{x}; t_b - t) = \mathbf{p}(\mathbf{x}, \mathbf{x}_a; t - t_a)$, after expressing $\mathbf{p}(\mathbf{x}, \mathbf{x}_a; t - t_a)$ explicitly in terms of the variables \mathbf{x}_b and \mathbf{x}_a as $\mathbf{p}(\mathbf{x}(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a), \mathbf{x}_a; t - t_a)$, to enable us to hold \mathbf{x}_b fixed in the second partial derivative:

$$\frac{\partial \mathbf{p}'}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} = \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} = \frac{\partial \mathbf{p}(\mathbf{x}(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a), \mathbf{x}_a; t - t_a)}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} = \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \Big|_{\mathbf{x}} \frac{\partial \mathbf{x}_a}{\partial \mathbf{x}} \Big|_{\mathbf{x}_b} + \frac{\partial \mathbf{p}}{\partial \mathbf{x}} \Big|_{\mathbf{x}_a}. \quad (4.137)$$

It may be expected, and can indeed be proved, that it is possible to proceed in the opposite direction and derive the semiclassical expressions (4.125) and (4.127) with the Van Vleck-Pauli-Morette determinant from the fundamental composition law (4.132).⁷

In the semiclassical approximation, the composition law (4.132) can also be written as a temporal integral (in D dimensions)

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a) = \int dt (\mathbf{x}_b t_b | \mathbf{x}_{cl}(t) t) \dot{\mathbf{x}}_{cl}(t) (\mathbf{x}_{cl}(t) t | \mathbf{x}_a t_a) \quad (4.138)$$

over a classical orbit $\mathbf{x}_{cl}(t)$, where the t -integration is done in the saddle point approximation, assuming that the fluctuation determinant does not happen to be degenerate.

Just as in the saddle point expansion of ordinary integrals, it is possible to calculate higher corrections in \hbar . The result is a saddle point expansion of the path

⁷H. Kleinert and B. Van den Bossche, Berlin preprint 2000 (<http://www.physik.fu-berlin.de/~kleinert/301>).

integral which is again a semiclassical expansion. The counting of the \hbar -powers is the same as for the integral. The lowest approximation is of the exponential form $e^{i\mathcal{A}_{cl}/\hbar}$. Thus, in the exponent, the leading term is of order $1/\hbar$.⁸ The fluctuation factor F contributes to this an additive term $\log F$, which is of order \hbar^0 . To first order in \hbar , one finds expressions containing the third and fourth functional derivative of the action in the expansion (4.99), corresponding to the expressions (4.49) and (4.50) in the integral. Unfortunately, the functional case offers little opportunity for further analytic corrections, so we shall not dwell on this more academic possibility.

4.5 Semiclassical Fixed-Energy Amplitude

As pointed out at the end of Subsection 4.2.1, we have observed that the semiclassical approximation allows for a simple evaluation of Fourier integrals. As an application of the rules presented there, let us evaluate the Fourier transform of the time evolution amplitude, the fixed-energy amplitude introduced in (1.311). It is given by the temporal integral

$$(x_b|x_a)_E = \frac{1}{\sqrt{2\pi i\hbar}} \int_{t_a}^{\infty} dt_b [-\partial_{x_b} \partial_{x_a} A(x_b, x_a; t_b - t_a)]^{1/2} \times e^{i[A(x_b, x_a; t_b - t_a) + (t_b - t_a)E]/\hbar}, \quad (4.139)$$

which may be evaluated in the same saddle point approximation as the path integral. The extremum lies at

$$\frac{\partial}{\partial t} A(x_b, x_a; t_b - t_a) = -E. \quad (4.140)$$

Because of (4.93), the left-hand side is the function $-E(x_b, x_a; t_b - t_a)$. At the extremum, the time interval $t_b - t_a$ is some function of the endpoints and the energy E :

$$t_b - t_a = t(x_b, x_a; E). \quad (4.141)$$

The exponent is equal to the eikonal function $S(x_b, x_a; E)$ of Eq. (4.87), whose derivative with respect to the energy gives [recalling (4.92)]

$$\frac{\partial}{\partial E} S(x_b, x_a; E) = t(x_b, x_a; E). \quad (4.142)$$

The expansion of the exponent around the extremum has the quadratic term

$$\frac{i}{\hbar} \frac{\partial^2 A(x_b, x_a; t_b - t_a)}{\partial t_b^2} [t_b - t_a - t(x_b, x_a; E)]^2. \quad (4.143)$$

The time integral over t_b yields a factor

$$\sqrt{2\pi i\hbar} \left[\frac{\partial^2 A(x_b, x_a; t_b - t_a)}{\partial t_b^2} \right]^{-1/2}. \quad (4.144)$$

⁸Since \hbar has the dimension of an action, the dimensionless number \hbar/\mathcal{A}_{cl} should really be used as an appropriate dimensionless expansion parameter, but it has become customary to count directly the orders in \hbar .

With this, the fixed-energy amplitude has precisely the form (4.55):

$$(x_b|x_a)_E = \left[-\partial_{x_b}\partial_{x_a}A(x_b, x_a; t)/\partial_t^2 A(x_b, x_a; t) \right]^{1/2} e^{iS(x_b, x_a; E)/\hbar}. \quad (4.145)$$

Since the fluctuation factor has to be evaluated at a fixed energy E , it is advantageous to express it in terms of $S(x_b, x_a; E)$. For $\partial_t^2 A$, the evaluation is simple since

$$\frac{\partial^2 A}{\partial t^2} = -\frac{\partial E}{\partial t} = -\left(\frac{\partial t}{\partial E}\right)^{-1} = -\left(\frac{\partial^2 S}{\partial E^2}\right)^{-1}. \quad (4.146)$$

For $\partial_{x_b}\partial_{x_a}A$, we observe that the spatial derivatives of the action must be performed at a fixed time, so that a variation of x_b implies also a change of the energy $E(x_b, x_a; t)$. This is found from the condition

$$\frac{\partial t}{\partial x_b} = 0, \quad (4.147)$$

which after inserting (4.142), goes over into

$$\left. \frac{\partial^2 S}{\partial E \partial x_b} \right|_t = \frac{\partial^2 S}{\partial E \partial x_b} + \frac{\partial^2 S}{\partial E^2} \frac{\partial E}{\partial x_b} = 0. \quad (4.148)$$

We now use the relation

$$\left. \frac{\partial A}{\partial x_b} \right|_t = \left. \frac{\partial S}{\partial x_b} \right|_t - \left. \frac{\partial E}{\partial x_b} \right|_t t = \left. \frac{\partial S}{\partial x_b} + \frac{\partial S}{\partial E} \frac{\partial E}{\partial x_b} \right|_t - \left. \frac{\partial E}{\partial x_b} \right|_t t = \left. \frac{\partial S}{\partial x_b} \right|_E \quad (4.149)$$

and find from it

$$\begin{aligned} \left. \frac{\partial^2 A}{\partial x_b \partial x_a} \right|_t &= \frac{\partial^2 S}{\partial x_b \partial x_a} + \frac{\partial^2 S}{\partial x_b \partial E} \frac{\partial E}{\partial x_a} \\ &= \frac{\partial^2 S}{\partial x_b \partial x_a} - \frac{\partial^2 S}{\partial x_a \partial E} \frac{\partial^2 S}{\partial x_b \partial E} / \frac{\partial^2 S}{\partial E^2}. \end{aligned} \quad (4.150)$$

Thus the fixed-energy amplitude (4.139) takes the simple form

$$(x_b|x_a)_E = D_S^{1/2} e^{iS(x_b, x_a; E)/\hbar}, \quad (4.151)$$

with the 2×2 -determinant

$$D_S = \begin{vmatrix} \frac{\partial^2 S}{\partial x_b \partial x_a} & \frac{\partial^2 S}{\partial E \partial x_a} \\ \frac{\partial^2 S}{\partial x_b \partial E} & \frac{\partial^2 S}{\partial E^2} \end{vmatrix}. \quad (4.152)$$

The determinant can be simplified by the fact that a differentiation of the Hamilton-Jacobi equation

$$H\left(\frac{\partial S}{\partial x_b}, x_b\right) = E \quad (4.153)$$

with respect to x_a leads to the equation

$$\frac{\partial H}{\partial p_b} \frac{\partial^2 S}{\partial x_b \partial x_a} = \dot{x}_b \frac{\partial^2 S}{\partial x_b \partial x_a} = 0. \quad (4.154)$$

It implies the vanishing of the upper left element in (4.152), reducing D_S to

$$D_S = -\frac{\partial^2 S}{\partial x_b \partial E} \frac{\partial^2 S}{\partial x_a \partial E}. \quad (4.155)$$

Since $\partial S / \partial x_{b,a} = \pm p_{b,a}$ and $\partial p / \partial E = 1 / \dot{x}$, one arrives at

$$D_S = \frac{1}{\dot{x}_b \dot{x}_a}. \quad (4.156)$$

Let us calculate the semiclassical fixed-energy amplitude for a free particle. The classical action function is

$$A(x_b, x_a; t_b - t_a) = \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a}, \quad (4.157)$$

so that the function $E(x_b, x_a; t_b - t_a)$ is given by

$$E(x_b, x_a; t_b - t_a) = -\frac{\partial}{\partial t_b} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} = \frac{M}{2} \frac{(x_b - x_a)^2}{(t_b - t_a)^2}. \quad (4.158)$$

By a Legendre transformation, or directly from the defining equation (4.68), we calculate

$$S(x_b, x_a; E) = \sqrt{2ME} |x_b - x_a|. \quad (4.159)$$

From this we calculate the determinant (4.156) as

$$D_s = \frac{M}{2E}, \quad (4.160)$$

and the fixed-energy amplitude (4.151) becomes

$$(x_b | x_a)_E = \sqrt{\frac{M}{2E}} e^{i\sqrt{2ME}|x_b - x_a|/\hbar}. \quad (4.161)$$

4.6 Semiclassical Amplitude in Momentum Space

The simple way of finding Fourier transforms in the semiclassical approximation can be used to derive easily amplitudes in momentum space. Consider first the time evolution amplitude $(x_b t_b | x_a t_a)_{sc}$. The momentum space version is given by the two-dimensional Fourier integral [recall (2.37) and insert (4.103)]

$$(p_b t_b | p_a t_a)_{sc} = \int dx_b dx_a e^{-i(p_b x_b - p_a x_a)/\hbar} e^{iA(x_b, x_a; t_b - t_a)/\hbar} F(x_b, x_a; t_b - t_a). \quad (4.162)$$

The semiclassical evaluation according to the general rule (4.55) yields

$$(p_b t_b | p_a t_a)_{\text{sc}} = \frac{\sqrt{2\pi i \hbar}}{\sqrt{\det H}} [-\partial_{x_b} \partial_{x_a} A(x_b, x_a; t_b - t_a)]^{1/2} e^{i[A(x_b, x_a; t_b - t_a) - p_b x_b + p_a x_a]/\hbar}, \quad (4.163)$$

where H is the matrix

$$H = \begin{pmatrix} \partial_{x_b}^2 A(x_b, x_a; t_b - t_a) & \partial_{x_b} \partial_{x_a} A(x_b, x_a; t_b - t_a) \\ \partial_{x_a} \partial_{x_b} A(x_b, x_a; t_b - t_a) & \partial_{x_a}^2 A(x_b, x_a; t_b - t_a) \end{pmatrix}. \quad (4.164)$$

The exponent must be evaluated at the extremum with respect to x_b and x_a , which lies at

$$p_b = \partial_{x_b} A(x_b, x_a; t_b - t_a), \quad p_a = -\partial_{x_a} A(x_b, x_a; t_b - t_a). \quad (4.165)$$

The exponent contains then the Legendre transform of the action $A(x_b, x_a; t_b - t_a)$ which depends naturally on p_b and p_a :

$$A(p_b, p_a; t_b - t_a) = A(x_b, x_a; t_b - t_a) - p_b x_b + p_a x_a. \quad (4.166)$$

The inverse Legendre transformation to (4.165) is

$$x_b = -\partial_{p_b} A(x_b, x_a; t_b - t_a), \quad x_a = \partial_{x_b} A(x_b, x_a; t_b - t_a). \quad (4.167)$$

The important observation which greatly simplifies the result is that for a 2×2 matrix H_{ab} with $(a, b = 1, 2)$, the matrix element $-H_{12}/\det H$ is equal to H_{12} . By writing the matrix H and its inverse as

$$H = \begin{pmatrix} \frac{\partial p_b}{\partial x_b} & \frac{\partial p_b}{\partial x_a} \\ -\frac{\partial p_a}{\partial x_b} & -\frac{\partial p_a}{\partial x_a} \end{pmatrix}, \quad H^{-1} = \begin{pmatrix} \frac{\partial x_b}{\partial p_b} & -\frac{\partial x_b}{\partial p_a} \\ \frac{\partial x_a}{\partial p_b} & -\frac{\partial x_a}{\partial p_a} \end{pmatrix}, \quad (4.168)$$

we see that, just as in the Eqs. (2.278) and (2.279):

$$H_{12}^{-1} = \frac{\partial x_a}{\partial p_b} = \frac{\partial^2 A(p_b, p_a; t_b - t_a)}{\partial p_b \partial p_a}. \quad (4.169)$$

As a result, the semiclassical time evolution amplitude in momentum space (4.163) takes the simple form

$$(p_b t_b | p_a t_a)_{\text{sc}} = \frac{2\pi \hbar}{\sqrt{2\pi i \hbar}} [-\partial_{p_b} \partial_{p_a} A(p_b, p_a; t_b - t_a)]^{1/2} e^{iA(p_b, p_a; t_b - t_a)/\hbar}. \quad (4.170)$$

In D dimensions, this becomes

$$(\mathbf{p}_b t_b | \mathbf{p}_a t_a) = \frac{1}{\sqrt{2\pi i \hbar}^D} \left\{ \det_D [-\partial_{p_b^i} \partial_{p_a^j} A(\mathbf{p}_b, \mathbf{p}_a; t_b - t_a)] \right\}^{1/2} e^{iA(\mathbf{p}_b, \mathbf{p}_a; t_b - t_a)/\hbar}, \quad (4.171)$$

or

$$(\mathbf{p}_b t_b | \mathbf{p}_a t_a) = \frac{1}{\sqrt{2\pi i \hbar}^D} \left\{ \det_D \left[-\frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \right] \right\}^{1/2} e^{iA(\mathbf{p}_b, \mathbf{p}_a; t_b - t_a)/\hbar}, \quad (4.172)$$

these results being completely analogous to the x -space expression (4.125) and (4.127), respectively. As before, the subscripts a and b can be interchanged in the determinant.

If we apply these formulas to the harmonic oscillator with a time-dependent frequency, we obtain precisely the amplitude (2.285). Thus in this case, the semiclassical time evolution amplitude $(p_b t_b | p_a t_a)_{sc}$ happens to coincide with the exact one.

For a free particle with the action $A(x_b, x_a; t_b - t_a) = M(x_b - x_a)^2/2(t_b - t_a)$, the formula (4.163) cannot be applied since determinant of H vanishes, so that the saddle point approximation is inapplicable. The formal infinity one obtains when trying to apply Eq. (4.163) is a reflection of the δ -function in the exact expression (2.73), which has no semiclassical approximation. The Legendre transform of the action can, however, be calculated correctly and yields with the derivatives $p_b = \partial_{x_b} A(x_b, x_a; t_b - t_a) = p_a = -\partial_{x_a} A(x_b, x_a; t_b - t_a) = M(x_b - x_a)/(t_b - t_a) = p$ [recall (4.88)] the expression

$$A(p_b, p_a; t_b - t_a) = -\frac{p^2}{2}(t_b - t_a), \quad (4.173)$$

which agrees with the exponent of (2.73).

4.7 Semiclassical Quantum-Mechanical Partition Function

From the result (4.103) we can easily derive the quantum-mechanical partition function (1.540) in semiclassical approximation:

$$Z_{\text{QM}}^{\text{sc}}(t_b - t_a) = \int dx_a (x_a t_b | x_a t_a)_{sc} = \int dx_a F(x_a, x_a; t_b - t_a) e^{iA(x_a, x_a; t_b - t_a)/\hbar}. \quad (4.174)$$

Within the semiclassical approximation the path integral, as the final trace integral may be performed using the saddle point approximation. At the saddle point one has [as in (4.133)]

$$\begin{aligned} \frac{\partial}{\partial x_a} A(x_a, x_a; t_b - t_a) &= \frac{\partial}{\partial x_b} A(x_b, x_a; t_b - t_a) \Big|_{x_b=x_a} + \frac{\partial}{\partial x_a} A(x_b, x_a; t_b - t_a) \Big|_{x_b=x_a} \\ &= p_b - p_a = 0, \end{aligned} \quad (4.175)$$

i.e., only classical orbits contribute whose momenta are equal at the coinciding end-points. This restricts the orbits to periodic solutions of the equations of motion. The semiclassical limit selects, among all paths with $x_a = x_b$, the paths solving the equation of motion, ensuring the continuity of the internal momenta along these

paths. The integration in (4.174) enforces the equality of the initial and final momenta on these paths and permits a continuation of the equations of motion beyond the final time t_b in a periodic fashion, leading to periodic orbits. Along each of these orbits, the energy $E(x_a, x_a, t_b - t_a)$ and the action $A(x_a, x_a, t_b - t_a)$ do not depend on the choice of x_a . The phase factor $e^{iA/\hbar}$ in the integral (4.174) is therefore a constant. The integral must be performed over a full period between the turning points of each orbit in the forward and backward direction. It contains a nontrivial x_a -dependence only in the fluctuation factor. Thus, (4.174) can be written as

$$Z_{\text{QM}}^{\text{sc}}(t_b - t_a) = \left[\int dx_a F(x_a, x_a; t_b - t_a) \right] e^{iA(x_a, x_a; t_b - t_a)/\hbar}. \quad (4.176)$$

For the integration over the fluctuation factor we use the expression (4.123) and the equation

$$\frac{\partial}{\partial x_b} \frac{\partial}{\partial x_a} A(x_b, x_a; t_b - t_a) = -\frac{1}{\dot{x}_b \dot{x}_a} \frac{\partial^2 A}{\partial t_b^2}, \quad (4.177)$$

following from (4.119) and (4.93), and have

$$F(x_b, x_a; t_b - t_a) = \frac{1}{\sqrt{2\pi i \hbar}} \left[\frac{1}{\dot{x}(t_b) \dot{x}(t_a)} \frac{\partial^2 A}{\partial t_b^2} \right]^{1/2}. \quad (4.178)$$

Inserting $x_a = x_b$ leads to

$$F(x_a, x_a; t_b - t_a) = \frac{1}{\sqrt{2\pi i \hbar}} \frac{1}{\dot{x}_a} \left[\frac{\partial^2 A}{\partial t_b^2} \right]^{1/2}. \quad (4.179)$$

The action of a periodic path does not depend on x_a , so that the x_b -integration in (4.174) requires only integrating $1/\dot{x}_a$ forward and back, which produces the total period:

$$t_b - t_a = 2 \int_{x_-}^{x_+} dx_a \frac{1}{\dot{x}_a} = 2 \int_{x_-}^{x_+} dx \frac{M}{\sqrt{2M[E - V(x)]}}. \quad (4.180)$$

Hence we obtain from (4.174):

$$Z_{\text{QM}}^{\text{sc}}(t_b - t_a) = \frac{t_b - t_a}{\sqrt{2\pi i \hbar}} \left| \frac{\partial^2 A}{\partial t_b^2} \right|^{1/2} e^{iA(t_b - t_a)/\hbar - i\pi}. \quad (4.181)$$

There is a phase factor $e^{-i\pi}$ associated with a Maslov-Morse index $\nu = 2$, first introduced in the fluctuation factor (2.271). In the present context, this phase factor arises from the fact that when doing the integral (4.176), the periodic orbit passes through the turning points x_- and x_+ where the integrand of (4.180) becomes singular, even though the integral remains finite. Near the turning points, the semiclassical approximation breaks down, as discussed in Section 4.1 in the context of the

WKB approximation to the Schrödinger equation. This breakdown required special attention in the derivation of the connection formulas relating the wave functions on one side of the turning points to those on the other side. There, the breakdown was circumvented by escaping into the complex x -plane. When going around the singularity in the clockwise sense, the prefactor $1/p(x) = 1/\sqrt{2M(E - V(x))}^{1/2}$ acquired a phase factor $e^{-i\pi/2}$. For a periodic orbit, both turning points had to be encircled producing twice this phase factor, which is precisely the phase $e^{-i\pi}$ given in (4.181).

The result (4.181) takes an especially simple form after a Fourier transform action:

$$\begin{aligned}\tilde{Z}_{\text{QM}}^{\text{sc}}(E) &= \int_{t_a}^{\infty} dt_b e^{iE(t_b - t_a)/\hbar} Z_{\text{QM}}^{\text{sc}}(t_b - t_a) \\ &= \frac{1}{\sqrt{2\pi i \hbar}} \int_{t_a}^{\infty} dt_b (t_b - t_a) \left| \frac{\partial^2 A}{\partial t_b^2} \right|^{1/2} e^{i[A(t_b - t_a) + (t_b - t_a)E]/\hbar - i\pi}.\end{aligned}\quad (4.182)$$

In the semiclassical approximation, the main contribution to the integral at a given energy E comes from the time where $t_b - t_a$ is equal to the period of the particle orbit with this energy. It is determined as in (4.139) by the extremum of

$$A(t_b - t_a) + (t_b - t_a)E. \quad (4.183)$$

Thus it satisfies

$$-\frac{\partial}{\partial t_b} A(t_b - t_a) = E. \quad (4.184)$$

As in (4.140), the extremum determines the period $t_b - t_a$ of the orbit with an energy E . It will be denoted by $t(E)$. The second derivative of the exponent is $(i/\hbar)\partial^2 A(t_b - t_a)/\partial t_b^2$. For this reason, the quadratic correction in the saddle point approximation to the integral over t_b cancels the corresponding prefactor in (4.182) and leads to the simple expression

$$\tilde{Z}_{\text{QM}}^{\text{sc}}(E) = t(E) e^{i[A(t) + t(E)E]/\hbar - i\pi}. \quad (4.185)$$

The exponent contains again the eikonal $S(E) = A(t) + t(E)E$, the Legendre transform of the action $A(t)$ defined by

$$S(E) = A(t) - t \frac{\partial A(t)}{\partial t}, \quad (4.186)$$

where the variable t has to be replaced by $E(t) = -\partial A(t)/\partial t$. Via the inverse Legendre transformation, the derivative $\partial S(E)/\partial E = t$ leads back to

$$A(t) = S(E) - \frac{\partial S(E)}{\partial E} E. \quad (4.187)$$

Explicitly, $S(E)$ is given by the integral (4.68):

$$S(E) = 2 \int_{x_-}^{x_+} dx p(x) = 2 \int_{x_-}^{x_+} dx \sqrt{2M[E - V(x)]}. \quad (4.188)$$

Finally, we have to take into account that the periodic orbit is repeatedly traversed for an arbitrary number of times. Each period yields a phase factor $e^{iS(E)/\hbar - i\pi}$. The sum is

$$\tilde{Z}_{\text{QM}}^{\text{sc}}(E) = \sum_{n=1}^{\infty} t(E) e^{in[S(E)/\hbar - \pi]} = -t(E) \frac{e^{iS(E)/\hbar}}{1 + e^{iS(E)/\hbar}}. \quad (4.189)$$

This expression possesses poles in the complex energy plane at points where the eikonal satisfies the condition

$$S(E_n) = 2\pi\hbar(n + 1/2), \quad n = 0, \pm 1, \pm 2, \dots \quad (4.190)$$

This condition agrees precisely with the Bohr-Sommerfeld rule (4.27) for semiclassical quantization. At the poles, one has

$$\tilde{Z}_{\text{QM}}^{\text{sc}}(E) \approx t(E) \frac{i\hbar}{S'(E_n)(E - E_n)}. \quad (4.191)$$

Due to (4.92), the pole terms acquire the simple form

$$\tilde{Z}_{\text{QM}}^{\text{sc}}(E) \approx \frac{i\hbar}{E - E_n}. \quad (4.192)$$

From (4.189) we derive the density of states defined in (1.583). For this we use the general formula

$$\rho(E) = \frac{1}{2\pi\hbar} \text{disc } \tilde{Z}_{\text{QM}}(E), \quad (4.193)$$

where $\text{disc } Z_{\text{QM}}(E)$ is the discontinuity $Z_{\text{QM}}(E + i\eta) - Z_{\text{QM}}(E - i\eta)$ across the singularities defined in Eq. (1.328). If we equip the energies E_n in (4.192) with the usual small imaginary part $-i\eta$, we can also write (4.193) as

$$\rho(E) = \frac{1}{\pi\hbar} \text{Re} \tilde{Z}_{\text{QM}}(E). \quad (4.194)$$

Inserting here the Fourier representation (4.189), we obtain the semiclassical approximation

$$\bar{\rho}_{\text{sc}}(E) = \frac{t(E)}{\pi\hbar} \sum_{n=1}^{\infty} \cos\{n[S(E)/\hbar - \pi]\} \quad (4.195)$$

or

$$\Delta\rho_{\text{sc}}(E) = \frac{t(E)}{2\pi\hbar} \left(-1 + \sum_{n=-\infty}^{\infty} e^{in[S(E)/\hbar - \pi]} \right). \quad (4.196)$$

We have added a Δ -symbol to this quantity since it is really the semiclassical correction to the classical density of states $\rho(E)$, as we shall see in a moment. With the help of Poisson's summation formula (1.197), this goes over into

$$\Delta\rho_{\text{sc}}(E) = -\frac{t(E)}{2\pi\hbar} + \frac{t(E)}{\hbar} \sum_{n=-\infty}^{\infty} \delta[S(E)/\hbar - 2\pi(n + 1/2)]. \quad (4.197)$$

The right-hand side contains δ -functions which are singular at the semiclassical energy values (4.190). Using once more the relation (4.92), the formula $\delta(ax) = a^{-1}\delta(x)$ leads to the simple expression

$$\Delta\rho_{\text{sc}}(E) = -\frac{t(E)}{2\pi\hbar} + \sum_{n=-\infty}^{\infty} \delta(E - E_n). \quad (4.198)$$

This result has a surprising property: Consider the spacing between the energy levels

$$\Delta E_n = E_n - E_{n-1} = 2\pi\hbar \frac{\Delta E_n}{\Delta S_n} \quad (4.199)$$

and average the sum in (4.198) over a small energy interval ΔE containing several energy levels. Then we obtain an average density of states:

$$\rho_{\text{av}}(E) = \frac{S'(E)}{2\pi\hbar} = \frac{t(E)}{2\pi\hbar}. \quad (4.200)$$

It cancels precisely the first term in (4.198). Thus, the semiclassical formula (4.189) possesses a vanishing average density of states. This cannot be correct and we conclude that in the derivation of the formula, a contribution must have been overlooked. This contribution comes from the classical partition function. Within the above analysis of periodic orbits, there are also those which return to the point of departure after an infinitesimally small time (which leaves them with no time to fluctuate). The expansion (4.189) does not contain them, since the saddle point approximation to the time integration (4.182) used for its derivation fails at short times. The reason for this failure is the singular behavior of the fluctuation factor $\propto 1/(t_b - t_a)^{1/2}$ in (4.103).

In order to recover the classical contribution, one simply uses the short-time amplitude in the form (2.349) to calculate the purely classical contribution to $Z(E)$:

$$Z_{\text{cl}}(E) \equiv \int dx \int \frac{dp}{2\pi\hbar} \frac{i\hbar}{E - H(p, x)}. \quad (4.201)$$

This implies a classical contribution to the density of states

$$\rho_{\text{cl}}(E) \equiv \int dx \rho_{\text{cl}}(E; x), \quad (4.202)$$

which is a spatial integral over the *classical local density of states*

$$\rho_{\text{cl}}(E; x) \equiv \int \frac{dp}{2\pi\hbar} \delta[E - H(p, x)]. \quad (4.203)$$

The δ -function in the integrand can be rewritten as

$$\delta(E - H(p, x)) = \frac{M}{p(E; x)} [\delta(p - p(E; x)) + \delta(p + p(E; x))], \quad (4.204)$$

where $p(E; x)$ is the local momentum associated with the energy E

$$p(E; x) = \sqrt{2M[E - V(x)]}, \quad (4.205)$$

which was defined in (4.3), except that we have now added the energy to the argument, to have a more explicit notation. It is then trivial to evaluate the integral (4.203) and (4.202) yielding the classical local density of states

$$\rho_{\text{cl}}(E; x) = \frac{1}{\pi\hbar} \frac{M}{p(E; x)}, \quad (4.206)$$

and its integral

$$\rho_{\text{cl}}(E) = \int dx \frac{1}{\pi\hbar} \frac{M}{p(E; x)} = \frac{1}{2\pi\hbar} t(E) = \rho_{\text{av}}(E), \quad (4.207)$$

which coincides with the average classical density of states in (4.200).

Thus the full semiclassical density of states consists of the sum of (4.198) and (4.207):

$$\rho_{\text{sc}}(E) = \rho_{\text{cl}}(E) + \Delta\rho_{\text{sc}}(E). \quad (4.208)$$

This has, on the average, the correct classical value.

Note that by Eq. (4.200), the eikonal $S(E)$ is related to the integral over the classical density of states $\rho_{\text{cl}}(E)$ by a factor $2\pi\hbar$:

$$S(E) = 2\pi\hbar \int_{-\infty}^E dE \rho_{\text{cl}}(E). \quad (4.209)$$

Recalling the definition (1.587) of the number of states up to the energy E we see that

$$S(E) = 2\pi\hbar N(E), \quad (4.210)$$

which shows that the Bohr-Sommerfeld quantization condition (4.190) is the semiclassical version of the completely general equation (1.588).

4.8 Multi-Dimensional Systems

The D -dimensional generalization of the classical partition function (4.201) reads

$$Z_{\text{cl}}(E) \equiv \int d^D x \int \frac{d^D p}{2\pi\hbar} \frac{i\hbar}{E - H(\mathbf{p}, \mathbf{x})}, \quad (4.211)$$

and of the density of states (4.203):

$$\rho_{\text{cl}}(E; \mathbf{x}) \equiv \int \frac{d^D p}{(2\pi\hbar)^D} \delta[E - H(\mathbf{p}, \mathbf{x})]. \quad (4.212)$$

The Hamiltonian of the standard form $H(\mathbf{p}, \mathbf{x}) = \mathbf{p}^2/2M + V(\mathbf{x})$ allows us to perform the momentum integration by separating it into radial and angular parts,

$$\int \frac{d^D p}{(2\pi\hbar)^D} = \int dp p^{D-1} \int d\hat{\mathbf{p}}. \quad (4.213)$$

The angular integral yields the surface of a unit sphere in D dimensions:

$$\int d\hat{\mathbf{p}} = S_D = \frac{2\pi^{D/2}}{\Gamma(D/2)}. \quad (4.214)$$

The δ -function $\delta(E - H(\mathbf{p}, \mathbf{x}))$ can again be rewritten as in (4.204), which selects the momenta of magnitude

$$p(E; \mathbf{x}) = \sqrt{2M[E - V(\mathbf{x})]}. \quad (4.215)$$

Thus we find

$$\rho_{\text{cl}}(E) \equiv \int d^D x \rho_{\text{cl}}(E; \mathbf{x}), \quad (4.216)$$

where $\rho_{\text{cl}}(E; \mathbf{x})$ is the *classical local density of states*.

$$\rho_{\text{cl}}(E; \mathbf{x}) = S_D \frac{M}{p^2(E; \mathbf{x})} \frac{p^D(E; \mathbf{x})}{(2\pi\hbar)^D} = \frac{1}{(4\pi\hbar^2)^{D/2}} \frac{2M}{\Gamma(D/2)} \{2M[E - V(\mathbf{x})]\}^{D/2-1}, \quad (4.217)$$

generalizing expression (4.207). The number of states with energies between E and $E + dE$ in the volume element $d^D x$ is $dE d^3 x \rho_{\text{cl}}(E; \mathbf{x})$.

For completeness we state some features of the semiclassical results which appear when generalizing the theory to D dimensions. For a detailed derivation see the rich literature on this subject quoted at the end of the chapter.

For an arbitrary number D of dimensions, the Van Vleck-Pauli-Morette determinant (4.124) takes the form

$$F(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a) = \frac{1}{\sqrt{2\pi i\hbar}^D} \left| \det_D [-\partial_{x_b^i} \partial_{x_a^j} A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)] \right|^{1/2} e^{-i\pi\nu/2}, \quad (4.218)$$

where ν is the Maslov-Morse index.

The fixed-energy amplitude becomes the sum over all periodic orbits:⁹

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \frac{1}{\sqrt{2\pi i\hbar}^{D-1}} \sum_p |D_S|^{1/2} e^{iS(\mathbf{x}_b, \mathbf{x}_a; E)/\hbar - i\pi\nu'/2}, \quad (4.219)$$

where $S(\mathbf{x}_b, \mathbf{x}_a; E)$ is the D -dimensional generalization of (4.68) and D_S the $(D + 1) \times (D + 1)$ -determinant:

$$D_S = (-1)^{D+1} \det \begin{pmatrix} \frac{\partial^2 S}{\partial \mathbf{x}_b \partial \mathbf{x}_a} & \frac{\partial^2 S}{\partial E \partial \mathbf{x}_a} \\ \frac{\partial^2 S}{\partial \mathbf{x}_b \partial E} & \frac{\partial^2 S}{\partial E \partial E} \end{pmatrix}. \quad (4.220)$$

⁹M.C. Gutzwiller, J. Math. Phys. 8, 1979 (1967); 11, 1791 (1970); 12, 343 (1971).

The factor $(-1)^{D+1}$ makes the determinant positive for short trajectories. The index ν' differs from ν by one unit if $\partial^2 S/\partial E^2 = \partial t(E)/\partial E$ is negative.

In D dimensions, the Hamilton-Jacobi equation leads to

$$\frac{\partial H}{\partial \mathbf{p}_b} \cdot \frac{\partial^2 S}{\partial \mathbf{x}_b \partial \mathbf{x}_a} = \dot{\mathbf{x}}_b \cdot \frac{\partial^2 S}{\partial \mathbf{x}_b \partial \mathbf{x}_a} = 0, \quad (4.221)$$

instead of (4.154). Only the longitudinal projection of the $D \times D$ -matrix $\partial^2 S/\partial \mathbf{x}_b \partial \mathbf{x}_a$ along the direction of motion vanishes now. In this direction

$$\dot{\mathbf{x}}_b \cdot \frac{\partial^2 S}{\partial \mathbf{x}_b \partial E} = 1, \quad (4.222)$$

so that the determinant (4.220) can be reduced to

$$D_S = \frac{1}{|\dot{\mathbf{x}}_b| |\dot{\mathbf{x}}_a|} \det \left(-\frac{\partial^2 S}{\partial \mathbf{x}_b^\perp \partial \mathbf{x}_a^\perp} \right), \quad (4.223)$$

instead of (4.156). Here $\mathbf{x}_{b,a}^\perp$ denotes the deviations from the orbit orthogonal to $\dot{\mathbf{x}}_{b,a}$, and we have used (2.290) to arrive at (4.223).

As an example, let us write down the D -dimensional generalization of the free-particle amplitude (4.161). The eikonal is obviously

$$S(\mathbf{x}_a, \mathbf{x}_b; E) = \sqrt{2ME} |\mathbf{x}_b - \mathbf{x}_a|, \quad (4.224)$$

and the determinant (4.223) becomes

$$D_S = \frac{M}{2E} \frac{(2ME)^{(D-1)/2}}{|\mathbf{x}_a - \mathbf{x}_b|^{D-1}}. \quad (4.225)$$

Thus we find

$$(\mathbf{x}_b | \mathbf{x}_a)_E = \sqrt{\frac{M}{2E}} \frac{1}{(2\pi i \hbar)^{(D-1)/2}} \frac{(2ME)^{(D-1)/4}}{|\mathbf{x}_a - \mathbf{x}_b|^{(D-1)/2}} e^{i\sqrt{2ME} |\mathbf{x}_b - \mathbf{x}_a|/\hbar}. \quad (4.226)$$

For $D = 1$, this reduces to (4.161).

Note that the semiclassical result coincides with the large-distance behavior (1.359) of the exact result (1.355), since the semiclassical limit implies a large momenta k in the Bessel function (1.355).

When calculating the partition function, one has to perform a D -dimensional integral over all $\mathbf{x}_b = \mathbf{x}_a$. This is best decomposed into a one-dimensional integral along the orbit and a $D - 1$ -dimensional one orthogonal to it. The eikonal function $S(\mathbf{x}_a, \mathbf{x}_a; E)$ is constant along the orbit, as in the one-dimensional case. When leaving the orbit, however, this is no longer true. The quadratic deviation of S orthogonal to the orbit is

$$\frac{1}{2} (\mathbf{x} - \mathbf{x}^\perp)^T \frac{\partial^2 S(\mathbf{x}, \mathbf{x}; E)}{\partial \mathbf{x}^\perp \partial \mathbf{x}^\perp} (\mathbf{x} - \mathbf{x}^\perp), \quad (4.227)$$

where the superscript T denotes the transposed vector to be multiplied from the left with the matrix in the middle. After the exact trace integration along the orbit and a quadratic approximation in the transversal direction for each primitive orbit, which is not repeated, we obtain the contribution to the partition function

$$Z_{sc} = t(E) \frac{\left| \frac{\partial^2 S(\mathbf{x}_b, \mathbf{x}_a; E)}{\partial \mathbf{x}_b^\perp \partial \mathbf{x}_a^\perp} \right|_{\mathbf{x}_b = \mathbf{x}_a = \mathbf{x}}^{1/2}}{\left| \frac{\partial^2 S(\mathbf{x}, \mathbf{x}; E)}{\partial \mathbf{x}^\perp \partial \mathbf{x}^\perp} \right|^{1/2}} \sum_{n=1}^{\infty} e^{in[S(E)/\hbar - i\pi\nu/2]}, \quad (4.228)$$

where ν is the Maslov-Morse index of the orbit. The ratio of the determinants is conveniently expressed in terms of the determinant of the so-called *stability matrix* M in phase space, which is introduced in classical mechanics as follows:

Consider a classical orbit in phase space and vary slightly the initial point, moving it orthogonally away from the orbit by $\delta \mathbf{x}_a^\perp, \delta \mathbf{p}_a^\perp$. This produces variations at the final point $\delta \mathbf{x}_b^\perp, \delta \mathbf{p}_b^\perp$, related to those at the initial point by the linear equation

$$\begin{pmatrix} \delta \mathbf{x}_b^\perp \\ \delta \mathbf{p}_b^\perp \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} \delta \mathbf{x}_a^\perp \\ \delta \mathbf{p}_a^\perp \end{pmatrix} \equiv M \begin{pmatrix} \delta \mathbf{x}_a^\perp \\ \delta \mathbf{p}_a^\perp \end{pmatrix}. \quad (4.229)$$

The $2(D-1) \times 2(D-1)$ -dimensional matrix is the stability matrix M . It can be expressed in terms of the second derivatives of $S(\mathbf{x}_b, \mathbf{x}_a; E)$. These appear in the relation

$$\begin{pmatrix} \delta \mathbf{p}_a^\perp \\ \delta \mathbf{p}_b^\perp \end{pmatrix} = \begin{pmatrix} -a & -b \\ b^T & c \end{pmatrix} \begin{pmatrix} \delta \mathbf{x}_a^\perp \\ \delta \mathbf{x}_b^\perp \end{pmatrix}, \quad (4.230)$$

where a, b , and c are the $(D-1) \times (D-1)$ -dimensional matrices

$$a = \frac{\partial^2 S}{\partial \mathbf{x}_a^\perp \partial \mathbf{x}_a^\perp}, \quad b = \frac{\partial^2 S}{\partial \mathbf{x}_a^\perp \partial \mathbf{x}_b^\perp}, \quad c = \frac{\partial^2 S}{\partial \mathbf{x}_b^\perp \partial \mathbf{x}_b^\perp}. \quad (4.231)$$

From this one calculates the matrix elements of the stability matrix (4.229):

$$A = -b^{-1}a, \quad B = -b^{-1}, \quad C = b^T - cb^{-1}a, \quad D = -cb^{-1}. \quad (4.232)$$

The stability properties of the classical orbits are classified by the eigenvalues of the stability matrix (4.229). In three dimensions, the eigenvalues are given by the zeros of the characteristic polynomial of the 4×4 -matrix M :

$$P(\lambda) = |M - \lambda| = \begin{vmatrix} A - \lambda & B \\ C & D - \lambda \end{vmatrix} = \begin{vmatrix} -b^{-1}a - \lambda & -b^{-1} \\ b^T - cb^{-1}a & -cb^{-1} - \lambda \end{vmatrix}. \quad (4.233)$$

The usual manipulations bring this to the form

$$\begin{aligned} P(\lambda) &= \begin{vmatrix} -b^{-1}a - \lambda & -b^{-1} \\ b^T + \lambda & -\lambda \end{vmatrix} = \frac{1}{|b|} \begin{vmatrix} -a - \lambda b & -1 \\ b^T + (a+c)\lambda + \lambda^2 b & 0 \end{vmatrix} \\ &= \frac{1}{|b|} |b^T + (a+c)\lambda + \lambda^2 b|. \end{aligned} \quad (4.234)$$

Precisely this expression appears, with $\mathbf{x}_b = \mathbf{x}_a$, in the prefactor of (4.228) if this is rewritten as

$$\frac{\left| \frac{\partial^2 S}{\partial \mathbf{x}_b^\perp \partial \mathbf{x}_a^\perp} \right|_{\mathbf{x}_b \approx \mathbf{x}_a = \mathbf{x}}^{1/2}}{\left| \frac{\partial^2 S}{\partial \mathbf{x}_b^\perp \partial \mathbf{x}_b^\perp} + 2 \frac{\partial S}{\partial \mathbf{x}_b^\perp} \frac{\partial S}{\partial \mathbf{x}_a^\perp} + \frac{\partial^2 S}{\partial \mathbf{x}_a^\perp \partial \mathbf{x}_a^\perp} \right|_{\mathbf{x}_b = \mathbf{x}_a = \mathbf{x}}^{1/2}}. \quad (4.235)$$

Due to (4.232), this coincides with $P(1)^{-1/2}$. The semiclassical limit to the quantum-mechanical partition function takes therefore the simple form referred to as *Gutzwiller's trace formula*

$$Z_{\text{sc}}(E) = t(E) \frac{1}{P(1)^{1/2}} \frac{e^{iS(E) - i\pi\nu/2}}{1 - e^{iS(E) - i\pi\nu/2}}. \quad (4.236)$$

The energy eigenvalues lie at the poles and satisfy the quantization rules [compare (4.27), (4.190)]

$$S(E_n) = 2\pi\hbar(n + \nu/4). \quad (4.237)$$

The eigenvalues of the stability matrix come always in pairs $\lambda, 1/\lambda$, as is obvious from (4.234). For this reason, one has to classify only two eigenvalues. These must be either both real or mutually complex-conjugate. One distinguishes the following cases:

1. *elliptic*, if $\lambda = e^{i\chi}, e^{-i\chi}$, with a real phase $\chi \neq 0$,
2. *direct parabolic*, if $\lambda = 1$,
inverse parabolic, if $\lambda = -1$,
3. *direct hyperbolic*, if $\lambda = e^{\pm\chi}$,
inverse hyperbolic, if $\lambda = -e^{\pm\chi}$,
4. *loxodromic*, if $\lambda = e^{u \pm iv}$.

In these cases,

$$P(1) = \prod_{i=1}^2 (\lambda_i - 1)(1/\lambda_i - 1) \quad (4.238)$$

has the values

1. $4 \sin^2(\chi/2)$,
2. 0 or 4 ,
3. $-4 \sinh^2(\chi/2)$ or $4 \cosh^2(\chi/2)$,
4. $4 \sin[(u + v)/2] \sin[(u - v)/2]$.

Only in the parabolic case are the equations of motion integrable, this being obviously an exception rather than a rule, since it requires the fulfillment of the equation $a + c = \pm 2b$. Actually, since the transverse part of the trace integration in the partition function results in a singular determinant in the denominator of (4.236), this case requires a careful treatment to arrive at the correct result.¹⁰ In general, a system will show a mixture of elliptic and hyperbolic behavior, and the particle orbits exhibit what is called a *smooth chaos*. In the case of a purely hyperbolic behavior one speaks of a *hard chaos*, which is simpler to understand. The semiclassical approximation is based precisely on those orbits of a system which are exceptional in a chaotic system, namely, the periodic orbits.

The expression (4.236) also serves to obtain the semiclassical density of states in D -dimensional systems via Eq. (4.193). In D dimensions the paths, with vanishing length contribute to the partition function the classical expression [compare (4.211)]. Application of semiclassical formulas has led to surprisingly simple explanations of extremely complex experimental data on highly excited atomic spectra which classically behave in a chaotic manner.

For completeness, let us also state the momentum space representation of the semiclassical fixed-energy amplitude (4.145). It is given by the momentum space analog of (4.219):

$$(\mathbf{p}_b|\mathbf{p}_a)_E = \frac{(2\pi\hbar)^D}{\sqrt{2\pi i\hbar}^{D-1}} \sum_p |\tilde{D}_S|^{1/2} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E)/\hbar - i\pi\nu'/2}, \quad (4.239)$$

where $S(\mathbf{p}_b, \mathbf{p}_a; E)$ is the Legendre transform of the eikonal

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = S(\mathbf{p}_b, \mathbf{p}_a; E) - \mathbf{p}_b \mathbf{x}_b + \mathbf{p}_a \mathbf{x}_a, \quad (4.240)$$

evaluated at the classical momenta $\mathbf{p}_b = \partial_{\mathbf{p}_b} S(\mathbf{p}_b, \mathbf{p}_a; E)$ and $\mathbf{p}_a = \partial_{\mathbf{p}_a} S(\mathbf{p}_b, \mathbf{p}_a; E)$. The determinant can be brought to the form:

$$D_S = \frac{1}{|\dot{\mathbf{p}}_b||\dot{\mathbf{p}}_a|} \det \left(-\frac{\partial^2 S}{\partial \mathbf{p}_b^\perp \partial \mathbf{p}_a^\perp} \right), \quad (4.241)$$

where \mathbf{p}_a^\perp is the momentum orthogonal to $\dot{\mathbf{p}}_a$.

This formula cannot be applied to the free particle fixed-energy amplitude (3.219) for the same degeneracy reason as before.

Higher \hbar -corrections to the trace formula (4.236) have also been derived, but the resulting expressions are very complicated to handle. See the citations at the end of this chapter.

4.9 Quantum Corrections to Classical Density of States

There exists a simple way of calculating quantum corrections to the semiclassical expressions (4.207) and its D -dimensional generalization (4.216) for the density of

¹⁰M.V. Berry and M. Tabor, J. Phys. A 10, 371 (1977), Proc. Roy. Soc. A 356, 375 (1977).

states. To derive them we introduce an operator δ -function $\delta(E - \hat{H})$ via the spectral representation

$$\delta(E - \hat{H}) \equiv \sum_n \delta(E - E_n) |n\rangle \langle n|, \quad (4.242)$$

where $|n\rangle$ are the eigenstates of the Hamiltonian operator \hat{H} . The δ -function (4.242) has the Fourier representation [recall (1.193)]

$$\delta(E - \hat{H}) = \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} e^{-i(\hat{H}-E)t/\hbar}. \quad (4.243)$$

Its matrix elements between eigenstates $|\mathbf{x}\rangle$ of the position operator,

$$\rho(E; \mathbf{x}) = \langle \mathbf{x} | \delta(E - \hat{H}) | \mathbf{x} \rangle = \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} e^{iEt/\hbar} \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x} \rangle, \quad (4.244)$$

define the *quantum-mechanical local density of states*. The amplitude on the right-hand side is the time evolution amplitude

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x} \rangle = (\mathbf{x} t | \mathbf{x} 0), \quad (4.245)$$

which can be represented by a path integral as described in Chapter 2. In the semiclassical limit, only the short-time behavior of $(\mathbf{x} t | \mathbf{x} 0)$ is relevant.

4.9.1 One-Dimensional Case

For a one-dimensional harmonic oscillator, the short-time expansion of (4.245) can easily be derived. We shall do this for a slightly generalized harmonic potential which contains also a linear term to

$$V(x) = \frac{\omega^2}{2}(x^2 - 2ax) = \frac{\omega^2}{2}(x - a)^2 - \frac{\omega^2}{2}a^2. \quad (4.246)$$

Then the diagonal amplitude (4.245) becomes [see also (2.333)]

$$(x t_b | x t_a) = \frac{1}{\sqrt{2\pi i \hbar / M}} \sqrt{\frac{\omega}{\sin \omega t}} \exp \left[i \frac{M\omega}{\hbar} \left(\tan \frac{\omega t}{2} (x - a)^2 - \frac{\omega t a^2}{2} \right) \right]. \quad (4.247)$$

For $t \equiv t_b - t_a < 1/\omega$, we expand this in a power series of t as follows:

$$(x t_b | x t_a) = \frac{e^{-i\frac{M}{2}\omega^2(x^2-2ax)t/\hbar}}{\sqrt{2\pi i \hbar t / M}} \left\{ 1 + \frac{t^2 \omega^2}{12} - \frac{iM}{\hbar} \frac{t^3}{24} \omega^4 (x - a)^2 + \frac{t^4 \omega^4}{160} - \frac{iM}{\hbar} \frac{11 t^5 \omega^2}{1440} \omega^4 (x - a)^2 + \dots \right\}. \quad (4.248)$$

This expansion can be generalized to an arbitrary smooth potential $V(x)$ if the exponential prefactor containing the harmonic potential is replaced by

$$e^{-iV(x)t/\hbar}, \quad (4.249)$$

whereas ω^2 and $\omega^4 x^2$ are substituted as follows:

$$\omega^2 \rightarrow \frac{1}{M} V''(x), \quad (4.250)$$

$$\omega^4 (x-a)^2 \rightarrow \frac{1}{M^2} [V'(x)]^2. \quad (4.251)$$

The presence of a is important for this identification. Without it we could not tell whether the harmonic term $\omega^4 x^2$ represents $[V'(x)]^2/M^2$ or $2V(x)V''(x)/M^2$. Thus we find

$$\begin{aligned} \langle x t_b | x t_a \rangle = \frac{e^{-iV(x)t/\hbar}}{\sqrt{2\pi i \hbar t/M}} \left\{ 1 + \frac{t^2}{12M} V''(x) - \frac{i}{\hbar} \frac{t^3}{24M} [V'(x)]^2 \right. \\ \left. + \frac{t^4}{160} [V''(x)]^2 - \frac{i}{\hbar} \frac{11t^5}{1440M} [V'(x)]^2 V''(x) + \dots \right\}. \end{aligned} \quad (4.252)$$

For positive $E - V(x)$, the integration along the real axis can be deformed into the upper complex plane to enclose the square-root cut along the positive imaginary t -axis in the anti-clockwise sense. Setting $t = i\tau$ and using the fact that the discontinuity across a square root cut produces a factor two, the lowest three terms become

$$\rho(E; x) = 2 \int_0^\infty \frac{d\tau}{2\pi\hbar} \frac{e^{-[E-V(x)]\tau/\hbar}}{\sqrt{2\pi\hbar\tau/M}} \left\{ 1 - \frac{\tau^2}{12M} V''(x) - \frac{1}{\hbar} \frac{\tau^3}{24M} [V'(x)]^2 + \dots \right\}. \quad (4.253)$$

The first term can easily be integrated for $E > V(x)$, and yields the classical local density of states (4.207):

$$\rho_{\text{cl}}(E; x) = \frac{1}{\pi\hbar} \frac{M}{\sqrt{2M[E-V(x)]}} = \frac{M}{\pi\hbar} \frac{1}{p(E; x)}. \quad (4.254)$$

In order to calculate the effect of the correction terms in the expansion (4.253), we observe that a factor τ in the integrand is the same as a derivative $\hbar d/dV$ applied to the exponential. Thus we find directly the semiclassical expansion for the density of states (4.253), valid for $E > V(x)$:

$$\rho(E; x) = \left\{ 1 - \frac{\hbar^2}{12M} V''(x) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [V'(x)]^2 \frac{d^3}{dV^3} + \dots \right\} \rho_{\text{cl}}(E; x). \quad (4.255)$$

Inserting (4.254) and performing the differentiations with respect to V we obtain

$$\begin{aligned} \rho(E; x) = \frac{1}{\pi\hbar} \sqrt{\frac{M}{2}} \left\{ \frac{1}{[E-V(x)]^{1/2}} - \frac{\hbar^2}{12M} V''(x) \frac{3}{4} \frac{1}{[E-V(x)]^{5/2}} \right. \\ \left. - \frac{\hbar^2}{24M} [V'(x)]^2 \frac{15}{8} \frac{1}{[E-V(x)]^{7/2}} + \dots \right\}. \end{aligned} \quad (4.256)$$

Note that the higher expansion terms contain powers of higher and higher gradients of the potential. It is a so-called *gradient expansion* of the density of states.

The integral over (4.256) yields a gradient expansion for $\rho(E)$ [3]. The second term can be integrated by parts which, under the assumption that $V(x)$ vanishes at the boundaries, simply changes the sign of the third term, so that we find

$$\rho(E) = \frac{1}{\pi\hbar} \sqrt{\frac{M}{2}} \int dx \left\{ \frac{1}{[E - V(x)]^{1/2}} + \frac{\hbar^2}{24M} [V'(x)]^2 \frac{15}{8} \frac{1}{[E - V(x)]^{7/2}} + \dots \right\}. \quad (4.257)$$

4.9.2 Arbitrary Dimensions

In D dimensions, the short-time expansion of the time evolution amplitude (4.252) takes the form

$$\langle \mathbf{x} t_b | \mathbf{x} t_a \rangle = \frac{e^{-iV(\mathbf{x})t/\hbar}}{\sqrt{2\pi i\hbar t/M}^D} \left\{ 1 + \frac{t^2}{12M} \nabla^2 V(\mathbf{x}) - \frac{i}{\hbar} \frac{t^3}{24M} [\nabla V(\mathbf{x})]^2 + \dots \right\}. \quad (4.258)$$

Recalling the $i\eta$ -prescription on page 115, according to which the singularity at $t = 0$ has to be shifted slightly into the upper half plane by replacing $t \rightarrow t - i\eta$, we use the formula¹¹

$$\int_{-\infty}^{\infty} \frac{dt}{2\pi} \frac{1}{(it + \eta)^\nu} e^{ita} = \Theta(a) \frac{a^{\nu-1}}{\Gamma(\nu)} e^{-a\eta}, \quad (4.259)$$

and obtain the obvious generalization of (4.255):

$$\rho(E; \mathbf{x}) = \left\{ 1 - \frac{\hbar^2}{12M} \nabla^2 V(\mathbf{x}) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} \rho_{\text{cl}}(E; \mathbf{x}), \quad (4.260)$$

where $\rho_{\text{cl}}(E; \mathbf{x})$ is the classical D -dimensional local density of states (4.217). The way this appears here is quite different from that in the earlier classical calculation (4.212), which may be expressed with the help of the local momentum (4.215) as an integral

$$\rho_{\text{cl}}(E; \mathbf{x}) = \int \frac{d^D p}{(2\pi\hbar)^D} \delta[E - H(\mathbf{p}, \mathbf{x})] = \int \frac{d^D p}{(2\pi\hbar)^D} \frac{M}{p(E; \mathbf{x})} \delta[p - p(E; \mathbf{x})]. \quad (4.261)$$

In order to see the relation to the appearance in (4.260) we insert the Fourier decomposition of the leading term of the short-time expansion of the time evolution amplitude

$$\langle \mathbf{x} t | \mathbf{x} 0 \rangle_{\text{cl}} = \int \frac{d^D p}{(2\pi\hbar)^D} e^{-i[\mathbf{p}^2/2M + V(\mathbf{x})]t/\hbar} \quad (4.262)$$

¹¹I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 3.382.6. The formula is easily derived by expressing $(it + \eta)^{-\nu} = \Gamma^{-1}(\nu) \int_0^\infty d\tau \tau^{\nu-1} e^{-\tau(it+\eta)}$.

into the integral representation (4.244) which takes the form

$$\rho(E; \mathbf{x}) = \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} \int \frac{d^D p}{(2\pi\hbar)^D} e^{-i[p^2 - p^2(E; \mathbf{x})]t/2M\hbar}. \quad (4.263)$$

By doing the integral over the time first, the size of the momentum is fixed to the local momentum $p^2(E; \mathbf{x})$ resulting in the original representation (4.261). The expression (4.217) for the density of states, on the other hand, corresponds to first integrating over *all* momenta. The time integration selects from the result of this the correct local momenta $p^2(E; \mathbf{x})$.

This generalizes (4.256) to

$$\begin{aligned} \rho(E; \mathbf{x}) = & \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \left\{ \frac{1}{\Gamma(D/2)} [E - V(\mathbf{x})]^{D/2-1} \right. \\ & - \frac{\hbar^2}{12M} [\nabla^2 V(\mathbf{x})] \frac{1}{\Gamma(D/2-2)} [E - V(\mathbf{x})]^{D/2-3} \\ & \left. + \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{1}{\Gamma(D/2-3)} [E - V(\mathbf{x})]^{D/2-4} + \dots \right\}. \end{aligned} \quad (4.264)$$

When integrating the density (4.264) over all \mathbf{x} , the second term in the curly brackets can again be converted into the third term changing its sign, as in (4.257). The right-hand side can easily be integrated for all pure power potentials. This will be done in Appendix 4A.

4.9.3 Bilocal Density of States

It is useful to generalize the local density of states (4.244) and introduce a *bilocal density of states*:

$$\begin{aligned} \rho(E; \mathbf{x}_b, \mathbf{x}_a) &= \langle \mathbf{x}_b | \delta(E - \hat{H}) | \mathbf{x}_a \rangle = \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} e^{iEt/\hbar} \langle \mathbf{x}_b | e^{-i\hat{H}t/\hbar} | \mathbf{x}_a \rangle \\ &= \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} e^{iEt/\hbar} (\mathbf{x}_b | t | \mathbf{x}_a | 0). \end{aligned} \quad (4.265)$$

The semiclassical expansion requires now the nondiagonal version of the short-time expansions (4.258). For a D -dimensional harmonic oscillator, the expansion (4.248) with $a = 0$ is generalized to

$$\begin{aligned} (\mathbf{x}_b | t_b | \mathbf{x}_a | t_a) = & \frac{e^{iM\Delta\mathbf{x}^2/2t\hbar}}{\sqrt{2\pi i\hbar t/M}} e^{-iM\omega^2 \bar{\mathbf{x}}^2 t/2\hbar} \left\{ 1 + \frac{t^2 D}{12} \omega^2 - \frac{iM}{\hbar} \frac{t^3}{24} \omega^4 \bar{\mathbf{x}}^2 - \frac{iM}{\hbar} \frac{t}{24} \Delta\mathbf{x}^2 \omega^2 \right. \\ & \left. - \frac{iM}{\hbar} \frac{t^3}{1440} \Delta\mathbf{x}^2 \omega^4 - \frac{iM}{\hbar} \frac{t^3 D}{288} \Delta\mathbf{x}^2 \omega^4 + \frac{t^4 (D + \frac{5}{4} D^2)}{360} \omega^4 - \frac{1}{\hbar^2} \Delta\mathbf{x}^4 \frac{t^2}{1152} \omega^4 \bar{\mathbf{x}}^2 + \dots \right\}, \end{aligned} \quad (4.266)$$

where $\bar{\mathbf{x}} = (\mathbf{x}_b + \mathbf{x}_a)/2$ is the mean position of the two endpoints. In this expansion we have included all terms whose size is of the order t^4 , keeping in mind that $\Delta\mathbf{x}^2$

is of the order \hbar in a finite amplitude. Performing the substitutions (4.250) and (4.251), for $a = 0$, this expansion is generalized to

$$\begin{aligned}
(\mathbf{x}_b t_b | \mathbf{x}_a t_a) &= \frac{e^{iM\Delta\mathbf{x}^2/2t\hbar}}{\sqrt{2\pi i\hbar t/M}^D} e^{-iV(\bar{\mathbf{x}})t/\hbar} \left\{ 1 + \frac{t^2}{12M} \nabla^2 V - \frac{i}{\hbar} \frac{t^3}{24M} [\nabla V]^2 - \frac{i}{\hbar} \frac{t}{24} (\Delta\mathbf{x}\nabla)^2 V \right. \\
&\quad - \frac{i}{\hbar} \frac{t^3}{1440M} [(\Delta\mathbf{x}\nabla)\Delta x_i \nabla_j V] \nabla_i \nabla_j V - \frac{iM}{\hbar} \frac{t^3}{288} (\Delta\mathbf{x})^2 [\nabla^2 V]^2 + \frac{t^4}{360M^2} \left([\nabla_i \nabla_j V]^2 + \frac{5}{4} [\nabla V]^2 \right) \\
&\quad \left. - \frac{t^2}{1152\hbar^2} [\Delta x_i \Delta x_j \nabla_k \nabla_l V] [\Delta x_k \Delta x_l \nabla_i \nabla_j V] + \dots \right\}. \quad (4.267)
\end{aligned}$$

where we have omitted the arguments $\bar{\mathbf{x}}$ in all potentials. The substitution of the term $\Delta\mathbf{x}^2 M\omega^2$ in (4.266) by

$$\Delta\mathbf{x}^2 M\omega^2 \rightarrow (\Delta\mathbf{x}\nabla)^2 V(\bar{\mathbf{x}}), \quad (4.268)$$

rather than $\Delta\mathbf{x}^2 \nabla^2 V(\bar{\mathbf{x}})$, follows from the fact that there is no factor D . The other substitutions follow similarly.

For a derivation without the substitution tricks (4.250), (4.251), (4.268), see Appendix 4B.

A recursive calculation is possible by writing the amplitude as

$$(\mathbf{x} t | \mathbf{x}' 0) = \frac{e^{iM\Delta\mathbf{x}^2/2t\hbar}}{\sqrt{2\pi i\hbar t/M}^D} A(\mathbf{x}, \Delta\mathbf{x}, t), \quad (4.269)$$

with the the amplitude $A(\mathbf{x}, \Delta\mathbf{x}; t)$, satisfying the differential equation

$$\hbar i \partial_t A(\mathbf{x}, \Delta\mathbf{x}; t) = \left[-\frac{\hbar^2}{2M} \nabla^2 - V(\mathbf{x}) \right] A - \frac{i\hbar}{t} \Delta\mathbf{x}\nabla A(\mathbf{x}, \Delta\mathbf{x}; t). \quad (4.270)$$

After expanding

$$A(\mathbf{x}, \Delta\mathbf{x}; t) = 1 + \sum_{n=1}^{\infty} t^n \sum_{p=0}^{\infty} \Delta x_{i_1} \cdots \Delta x_{i_p} a_{i_1, \dots, i_p}^{(n)}(\mathbf{x}), \quad (4.271)$$

we can calculate the coefficients order by order in n and p .

Inserting the amplitude (4.267) into the integral in Eq. (4.265), we obtain from the lowest expansion terms the bilocal density of states

$$\begin{aligned}
\rho(E; \mathbf{x}_b, \mathbf{x}_a) &= \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} \frac{e^{iM\Delta\mathbf{x}^2/2t\hbar}}{\sqrt{2\pi i\hbar t/M}^D} e^{-i[V(\bar{\mathbf{x}})-E]t/\hbar} \\
&\quad \times \left\{ 1 + \frac{t^2}{12M} \nabla^2 V(\bar{\mathbf{x}}) - \frac{i}{\hbar} \frac{t^3}{24M} [\nabla V(\bar{\mathbf{x}})]^2 - \frac{i}{\hbar} \frac{t}{24} (\Delta\mathbf{x}\nabla)^2 V(\bar{\mathbf{x}}) + \dots \right\}. \quad (4.272)
\end{aligned}$$

The leading term is simply the time evolution amplitude of the free-particle in a constant potential $V(\bar{\mathbf{x}})$ which has the Fourier decomposition [recall (1.335)]:

$$(\mathbf{x}_b t_b | \mathbf{x}_a t_a)_{\text{cl}} = \int \frac{d^D p}{(2\pi\hbar)^D} e^{i\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a)/\hbar} e^{-iH(\mathbf{p}, \bar{\mathbf{x}})t/\hbar}. \quad (4.273)$$

Indeed, inserting this into (4.265), and performing the integration over time, we find

$$\rho_{\text{cl}}(E; \mathbf{x}_b, \mathbf{x}_a) = \int \frac{d^D p}{(2\pi\hbar)^D} \delta(E - H(\mathbf{p}, \bar{\mathbf{x}})) e^{i\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a)/\hbar}. \quad (4.274)$$

Decomposing the momentum integral into radial and angular parts as in (4.213), we can integrate out the radial part as in (4.203), whereas the angular integral yields the following function of $R = |\mathbf{x}_b - \mathbf{x}_a|$:

$$\int d\hat{\mathbf{p}} e^{i\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a)/\hbar} = S_D(pR/\hbar), \quad (4.275)$$

which is a direct generalization of the surface of a sphere in D dimensions (4.214). It reduces to it for $p = 0$. This integral will be calculated in Section 9.1. The result is

$$S_D(z) = (2\pi)^{D/2} J_{D/2-1}(z) / z^{D/2-1}, \quad (4.276)$$

where $J_\nu(z)$ are Bessel functions. For small z , these behave like¹²

$$J_\nu(z) \approx \frac{(z/2)^\nu}{\Gamma(\nu + 1)}, \quad (4.277)$$

thus ensuring that $S_D(kR)$ is indeed equal to S_D at $R = 0$.

Altogether, the classical limit of the bilocal density of states is

$$\rho_{\text{cl}}(E; \mathbf{x}_b, \mathbf{x}_a) = \left(\frac{1}{2\pi\hbar^2} \right)^{D/2} M \frac{J_{D/2-1}(p(E; \bar{\mathbf{x}})R/\hbar)}{(R/\hbar)^{D/2-1}}. \quad (4.278)$$

At $\mathbf{x}_b = \mathbf{x}_a$, this reduces to the density (4.212).

In three dimensions, the Bessel function becomes

$$J_{1/2}(z) = \sqrt{\frac{2}{\pi z}} \sin z, \quad (4.279)$$

and (4.278) yields

$$\rho_{\text{cl}}(E; \mathbf{x}_b, \mathbf{x}_a) = \left(\frac{1}{2\pi\hbar^2} \right)^{3/2} \frac{1}{\Gamma(3/2)} \frac{M \sin[p(E; \bar{\mathbf{x}})R/\hbar]}{\sqrt{2} R/\hbar}. \quad (4.280)$$

From the D -dimensional version of the short-time expansion (4.272) we obtain, after using once more the equivalence of t and $i\hbar d/dV$,

$$\begin{aligned} \rho(E; \mathbf{x}_b, \mathbf{x}_a) = & \left\{ 1 - \frac{\hbar^2}{12M} [\nabla^2 V(\bar{\mathbf{x}})] \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\bar{\mathbf{x}})]^2 \frac{d^3}{dV^3} \right. \\ & \left. + \frac{1}{24} [(\mathbf{x}_b - \mathbf{x}_a) \nabla]^2 V(\bar{\mathbf{x}}) \frac{d}{dV} + \dots \right\} \rho_{\text{cl}}(E; \mathbf{x}_b, \mathbf{x}_a). \end{aligned} \quad (4.281)$$

¹²M. Abramowitz and I. Stegun, *op. cit.*, Formula 9.1.7.

4.9.4 Gradient Expansions of Tracelog of Hamiltonian Operator

Starting point is formula (1.590) for the tracelog of the Hamiltonian operator. By performing the trace in the local basis $|\mathbf{x}\rangle$, we arrive at the useful formula involving the density of states (4.244)

$$\mathrm{Tr} \log \hat{H} = \int d^D x \int_{-\infty}^{\infty} dE \rho(E; \mathbf{x}) \log E. \quad (4.282)$$

Inserting here the classical density of states (4.217), the integral over the classical spectrum $E \in (E_0, \infty)$ can be performed, where E_0 is the bottom of the potential $V(\mathbf{x})$, and yields the classical limit of the tracelog:

$$[\mathrm{Tr} \log \hat{H}]_{\mathrm{cl}} = \int d^D x \int_{E_0}^{\infty} dE \rho_{\mathrm{cl}}(E; \mathbf{x}) \log E = \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \int d^D x I_{D/2}(V(\mathbf{x})), \quad (4.283)$$

where

$$I_{\alpha}(V) \equiv \frac{1}{\Gamma(\alpha)} \int_V^{\infty} dE (E - V)^{\alpha-1} \log E. \quad (4.284)$$

The integrals $I_{D/2}(V(\mathbf{x}))$ diverge, but can be calculated with the techniques explained in Section 2.15 from the analytically regularized integrals¹³

$$I_{\alpha}^{\eta}(V) \equiv \frac{1}{\Gamma(\alpha)} \int_V^{\infty} dE (E - V)^{\alpha-1} E^{-\eta} = V^{\alpha-\eta} \frac{\Gamma(-\alpha + \eta)}{\Gamma(\eta)}. \quad (4.285)$$

Since $E^{-\eta} = 1 - \eta \log E + \mathcal{O}(\eta^2)$, the coefficient of $-\eta$ in the Taylor series of $I_{\alpha}^{\eta}(V)$ will yield the desired integral. Since $1/\Gamma(\eta) \approx \eta$, we obtain directly

$$I_{\alpha}(V) = -\Gamma(-\alpha)V^{\alpha}, \quad (4.286)$$

so that (4.283) becomes

$$[\mathrm{Tr} \log \hat{H}]_{\mathrm{cl}} = - \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \Gamma(-D/2) \int d^D x [V(\mathbf{x})]^{D/2}. \quad (4.287)$$

The same result can be obtained with the help of formulas (4.244), (4.258), and (2.506) as

$$[\mathrm{Tr} \log \hat{H}]_{\mathrm{cl}} = - \int d^D x \int_{-\infty}^{\infty} dE \int_{-\infty}^{\infty} \frac{dt}{2\pi\hbar} \frac{e^{it[E-V(\mathbf{x})]/\hbar}}{(2\pi i \hbar t/M)^{D/2}} \int_0^{\infty} \frac{dt'}{t'} e^{-iEt'/\hbar}. \quad (4.288)$$

Integrating over the energy yields

$$[\mathrm{Tr} \log \hat{H}]_{\mathrm{cl}} = - \int d^D x \int_0^{\infty} \frac{dt}{t} \frac{1}{(2\pi i \hbar t/M)^{D/2}} e^{-itV(\mathbf{x})/\hbar}. \quad (4.289)$$

Deforming the contour of integration by the substitution $t = -i\tau$, we arrive at the integral representation of the Gamma function (2.498) which reproduces immediately the result (4.287).

The full quantum mechanical expression for the trace log contains the diagonal time evolution amplitude

$$\mathrm{Tr} \log \hat{H} = - \int d^D x \int_0^{\infty} \frac{dt}{t} \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x} \rangle. \quad (4.290)$$

Inserting here the short-time expansion (4.258), we obtain the semiclassical expansion for the trace of the logarithm. If the factors t^n in the integrand are replaced by derivatives with respect to the

¹³I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 3.196.2.

potential $V(\mathbf{x})$, we obtain the semiclassical expansion containing the prefactor in curly brackets in the expansion (4.260):

$$\begin{aligned} \text{Tr log } \hat{H} &= - \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \Gamma(-D/2) \\ &\times \int d^D x \left\{ 1 - \frac{\hbar^2}{12M} \nabla^2 V(\mathbf{x}) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} [V(\mathbf{x})]^{D/2}. \end{aligned} \quad (4.291)$$

The second term can be integrated by parts, which replaces $\nabla^2 V(\mathbf{x}) \rightarrow -[\nabla V(\mathbf{x})]^2/dV$, so that we obtain the gradient expansion

$$\text{Tr log } \hat{H} = - \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \Gamma(-D/2) \int d^D x \left\{ 1 + \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} [V(\mathbf{x})]^{D/2}. \quad (4.292)$$

The expression in curly brackets can obviously be replaced by

$$\left\{ 1 - \frac{\hbar^2}{24M} \frac{\Gamma(3-D/2)}{\Gamma(-D/2)} \frac{[\nabla V(\mathbf{x})]^2}{[V(\mathbf{x})]^3} + \dots \right\}. \quad (4.293)$$

In one dimension and with $M = 1/2$, this amounts to the formula

$$\text{Tr log}[-\hbar^2 \partial_x^2 + V(x)] = \frac{1}{\hbar} \int dx \sqrt{V(x)} \left\{ 1 + \frac{\hbar^2}{32} \frac{[V'(x)]^2}{V^3(x)} + \dots \right\}. \quad (4.294)$$

It is a useful exercise to rederive this with the help of the Gelfand-Yaglom method in Section 2.4.

There exists another method for deriving the gradient expansion (4.291). We split $V(\mathbf{x})$ into a constant term V and a small \mathbf{x} -dependent term $\delta V(\mathbf{x})$, and rewrite

$$\begin{aligned} \text{Tr log} \left[-\frac{\hbar^2}{2M} \nabla^2 + V(\mathbf{x}) \right] &= \text{Tr log} \left[-\frac{\hbar^2}{2M} \nabla^2 + V + \delta V(\mathbf{x}) \right] \\ &= \text{Tr log} \left(-\frac{\hbar^2}{2M} \nabla^2 + V \right) + \text{Tr log} (1 + \Delta_V \delta V), \end{aligned} \quad (4.295)$$

where Δ_V denotes the functional matrix

$$\Delta_V(\mathbf{x}, \mathbf{x}') = \left(-\frac{\hbar^2}{2M} \nabla^2 + V \right)^{-1} = \int \frac{d^D p}{(2\pi\hbar)^D} \frac{e^{i\mathbf{p}(\mathbf{x}-\mathbf{x}')/\hbar}}{\mathbf{p}^2/2M + V} \equiv \Delta_V(\mathbf{x} - \mathbf{x}'). \quad (4.296)$$

This coincides with the fixed-energy amplitude $(i/\hbar)(\mathbf{x}|\mathbf{x}')_E$ at $E = -V$ [recall Eq. (1.348)].

The first term in (4.295) is equal to (4.287) if we replace $V(\mathbf{x})$ in that expression by the constant V , so that we may write

$$\text{Tr log } \hat{H} = [\text{Tr log } \hat{H}]_{\text{cl}} \Big|_{V(\mathbf{x}) \rightarrow V} + \text{Tr log} (1 + \Delta_V \delta V). \quad (4.297)$$

We now expand the remainder

$$\text{Tr log} (1 + \Delta_V \delta V) = \text{Tr } \Delta_V \delta V - \frac{1}{2} \text{Tr} (\Delta_V \delta V)^2 + \dots, \quad (4.298)$$

and evaluate the expansion terms. The first term is simply

$$\text{Tr } \Delta_V \delta V = \int d^D x \Delta_V(\mathbf{x}, \mathbf{x}) \delta V(\mathbf{x}) = \Delta_V(\mathbf{0}) \int d^D x \delta V(\mathbf{x}). \quad (4.299)$$

where

$$\Delta_V(\mathbf{0}) = \int \frac{d^D p}{(2\pi\hbar)^D} \frac{1}{\mathbf{p}^2/2M + V} = \partial_V [\text{Tr log } \hat{H}]_{\text{cl}} \Big|_{V(\mathbf{x}) \rightarrow V}. \quad (4.300)$$

The result of the integration was given in Eq. (1.352).

The second term in the remainder (4.298) reads explicitly

$$-\frac{1}{2}\text{Tr} (\Delta_V \delta V)^2 = -\frac{1}{2} \int d^D x \int d^D x' \Delta_V(\mathbf{x}, \mathbf{x}') \delta V(\mathbf{x}') \Delta_V(\mathbf{x}', \mathbf{x}) \delta V(\mathbf{x}). \quad (4.301)$$

We now make use of the operator relation

$$[f(\hat{A}), \hat{B}] = f'(\hat{A})[\hat{A}, \hat{B}] - \frac{1}{2}f''(\hat{A})[\hat{A}, [\hat{A}, \hat{B}]] + \dots, \quad (4.302)$$

to expand

$$\delta V \Delta_V = \Delta_V \delta V + \Delta_V^2 [\hat{T}, \delta V] + \Delta_V^3 [\hat{T}, [\hat{T}, \delta V]] + \dots, \quad (4.303)$$

where \hat{T} is the operator of the kinetic energy $\hat{\mathbf{p}}^2/2M$. It commutes with any function $f(\mathbf{x})$ as follows:

$$[\hat{T}, f] = -\frac{\hbar^2}{2M} [(\nabla^2 f) + 2(\nabla f) \cdot \nabla], \quad (4.304)$$

$$[\hat{T}, [\hat{T}, f]] = \frac{\hbar^4}{4M^2} \{[(\nabla^2)^2 f] + 4[\nabla \nabla^2 f] \cdot \nabla + 4[\nabla_i \nabla_i f] \nabla_i \nabla_j\}, \quad (4.305)$$

\vdots

Inserting this into (4.301), we obtain a first contribution

$$-\frac{1}{2} \int d^D x \int d^D x' \Delta_V(\mathbf{x}, \mathbf{x}') \Delta_V(\mathbf{x}', \mathbf{x}) [\delta V(\mathbf{x})]^2. \quad (4.306)$$

The spatial integrals are performed by going to momentum space, where we derive the general formula

$$\begin{aligned} & \int d^D x \int d^D x_1 \cdots \int d^D x_n \Delta_V(\mathbf{x}, \mathbf{x}_1) \Delta_V(\mathbf{x}_1, \mathbf{x}_2) \cdots \Delta_V(\mathbf{x}_{n-1}, \mathbf{x}_n) \Delta_V(\mathbf{x}_n, \mathbf{x}) \\ &= \int \frac{d^D p}{(2\pi\hbar)^D} \frac{1}{(\mathbf{p}^2/2M + V)^{n+1}} = \frac{(-1)^n}{n!} \partial_V^n \Delta_V(\mathbf{0}). \end{aligned} \quad (4.307)$$

This simplifies (4.306) to

$$\frac{1}{2} \partial_V \Delta_V(\mathbf{0}) \int d^D x [\delta V(\mathbf{x})]^2. \quad (4.308)$$

We may now combine the non-gradient terms of $\delta V(\mathbf{x})$ consisting of the first term in (4.297), of (4.299), and of (4.308), and replace in the latter $\Delta_V(\mathbf{0})$ according to (4.300), to obtain the first three expansion terms of $[\text{Tr} \log \hat{H}]_{\text{cl}}$ with the full \mathbf{x} -dependent $V(\mathbf{x})$ in Eq. (4.287).

The next contribution to (4.301) coming from (4.304) is

$$\begin{aligned} & \frac{\hbar^2}{4M} \int d^D x \int d^D x_1 \int d^D x_2 \Delta_V(\mathbf{x}, \mathbf{x}_1) \Delta_V(\mathbf{x}_1, \mathbf{x}_2) \Delta_V(\mathbf{x}_2, \mathbf{x}) \\ & \times \left\{ [\nabla^2 \delta V(\mathbf{x})] \delta V(\mathbf{x}) + 2[\nabla \delta V(\mathbf{x})]^2 + 2[\nabla \delta V(\mathbf{x})] \delta V(\mathbf{x}) \nabla \right\}, \end{aligned} \quad (4.309)$$

where the last ∇ acts on the first \mathbf{x} in $\Delta_V(\mathbf{x}, \mathbf{x}_1)$, due to the trace. It does not contribute to the integral since it is odd in $\mathbf{x} - \mathbf{x}_1$.

We now perform the integrals over \mathbf{x}_1 and \mathbf{x}_2 using formula (4.307) and find

$$\frac{\hbar^2}{8M} \int d^D x \left\{ [\nabla^2 \delta V(\mathbf{x})] [\delta V(\mathbf{x})] + 2[\nabla \delta V(\mathbf{x})]^2 \right\} \partial_V^2 \Delta_V(\mathbf{0}). \quad (4.310)$$

The first term can be integrated by parts, after which it removes half of the second term.

A third contribution to (4.301) which contains only the lowest gradients of $\delta V(\mathbf{x})$ comes from the third term in (4.305):

$$-\frac{\hbar^4}{8M^2} \int d^D x \int d^D x_1 \int d^D x_2 \int d^D x_3 \Delta_V(\mathbf{x}, \mathbf{x}_1) \Delta_V(\mathbf{x}_1, \mathbf{x}_2) \Delta_V(\mathbf{x}_2, \mathbf{x}_3) \Delta_V(\mathbf{x}_3, \mathbf{x}) \\ \times 4 [\nabla_i \nabla_j \delta V(\mathbf{x})] \delta V(\mathbf{x}) \nabla_i \nabla_j, \quad (4.311)$$

where the last $\nabla_i \nabla_j$ acts again on we men the first \mathbf{x} in $\Delta_V(\mathbf{x}, \mathbf{x}_1)$, as a consequence of the trace. In momentum space, we encounter the integral

$$\int \frac{d^D p}{(2\pi\hbar)^D} \frac{-4p_i p_j / \hbar^2}{(\mathbf{p}^2 / 2M + V)^4} = -\frac{8M}{\hbar^2} \frac{\delta_{ij}}{D} \int \frac{d^D p}{(2\pi\hbar)^D} \left[\frac{1}{(\mathbf{p}^2 / 2M + V)^3} - \frac{V}{(\mathbf{p}^2 / 2M + V)^4} \right] \\ = -\frac{8M}{\hbar^2} \frac{\delta_{ij}}{D} \left(\frac{1}{2} \partial_V^2 + \frac{1}{6} V \partial_V^3 \right) \Delta_V(\mathbf{0}). \quad (4.312)$$

so that the third contribution to (4.301) reads, after an integration by parts,

$$-\frac{\hbar^2}{M} \int d^D x [\nabla \delta V(\mathbf{x})]^2 \frac{\delta_{ij}}{D} \left(\frac{1}{2} \partial_V^2 + \frac{1}{6} V \partial_V^3 \right) \Delta_V(\mathbf{0}). \quad (4.313)$$

Combining all gradient terms in $[\nabla V(\mathbf{x})]^2$ and replacing $\Delta_V(\mathbf{0})$ according to (4.300), we recover the previous result (4.292) with the curly brackets (4.293).

For the one-dimensional tracelog, this leads to the formula

$$\text{Tr} \log[-\hbar^2 \partial_x^2 + V(x)] = \frac{1}{\hbar} \int dx \sqrt{V(x)} \left\{ 1 + \frac{\hbar^2}{32} \frac{[V'(x)]^2}{V^3(x)} + \dots \right\}. \quad (4.314)$$

It is a useful exercise to rederive this with the help of the Gelfand-Yaglom method in Section 2.4.

This one-dimensional result can easily be carried to much higher order, with the help of the gradient expansion of the trace of the logarithm of the operator $-\hbar^2 \partial_\tau^2 + w^2(\tau)$ derived in Subsection 2.15.4. If we replace τ by x/\hbar and $v(\tau)$ by $V(x)$, we obtain from (2.550)–(2.552):

$$\frac{1}{\hbar} \int dx \sqrt{V(x)} \left\{ 1 - \hbar \frac{V'}{4V^{3/2}} - \hbar^2 \left(\frac{5V'^2}{32V^3} - \frac{V''}{8V^2} \right) - \hbar^3 \left(\frac{15V'^3}{64V^{9/2}} - \frac{9V'V''}{32V^{7/2}} + \frac{V^{(3)}}{16V^{5/2}} \right) \right. \\ \left. - \hbar^4 \left(\frac{1105V'^4}{2048V^6} - \frac{221V'^2V''}{256V^5} + \frac{19V''^2}{128V^4} + \frac{7V'V^{(3)}}{32V^4} - \frac{V^{(4)}}{32V^3} \right) \right\}. \quad (4.315)$$

The terms accompanying the odd powers of \hbar in the curly brackets can be combined to a total derivative and can be ignored if $V(x)$ is the same at the upper and lower boundaries. The \hbar^2 term goes over into the \hbar^2 -term in (4.314). The \hbar^4 -terms in the curly brackets can be integrated by parts, which brings $V'^4/V^6 \rightarrow \frac{2}{3} V'^2 V''/V^5$, $V'V^{(3)}/V^4 \rightarrow \frac{7}{2} V'^2 V''/V^5 - V''^2/V^4$, $V^{(4)}/V^3 \rightarrow \frac{35}{4} V'^2 V''/V^5 - \frac{5}{2} V''^2/V^4$, so that the total \hbar^4 -term is equivalent to $-\hbar^4 \left(-\frac{35}{3072} V'^2 V''/V^5 + \frac{1}{128} V''^2/V^4 \right)$.

A third procedure to find the gradient expansion is based on an operator calculation [4]. We write the amplitude in (4.265) as

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = e^{-it[\mathbf{p}^2/2M + V(\mathbf{x})]/\hbar} \langle \mathbf{x} | \mathbf{x}' \rangle = \int \frac{d^D k}{(2\pi)^D} e^{-it[-\hbar^2 \nabla^2/2M + V(\mathbf{x})]/\hbar} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')}, \quad (4.316)$$

and take the plane wave exponential to the left of the time evolution operator with the help of Lie's expansion formula (1.297)

$$e^{-i\mathbf{k}\mathbf{x}} \nabla e^{i\mathbf{k}\mathbf{x}} = \nabla + i\mathbf{k}. \quad (4.317)$$

In this way we obtain the formula

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')} e^{-it[-\hbar^2(\nabla+i\mathbf{k})^2/2M+V(\mathbf{x})]/\hbar}, \quad (4.318)$$

We rewrite this as

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')-it\hbar k^2/2M} e^{-itV(\mathbf{x})/\hbar} C(\mathbf{x}; \mathbf{k}, t) \quad (4.319)$$

where

$$C(\mathbf{x}; \mathbf{k}, t) \equiv e^{it[\hbar^2 k^2+V(\mathbf{x})]/\hbar} e^{-it[-\hbar^2(\nabla+i\mathbf{k})^2/2M+V(\mathbf{x})]/\hbar} = e^{itV(\mathbf{x})/\hbar} e^{-it[\hat{H}-i\hbar^2\mathbf{k}\nabla/M]/\hbar}. \quad (4.320)$$

We now expand $C(\mathbf{x}; \mathbf{k}, t)$ in powers of t :

$$C(\mathbf{x}; \mathbf{k}, t) = \sum_{n=0}^{\infty} t^n C^{(n)}(\mathbf{x}; \mathbf{k}). \quad (4.321)$$

The expansion coefficients are most easily obtained by expanding only the second exponential in powers of t and dropping the pure t th power of the potential $V(\mathbf{x})$. After this we evaluate the integrals over powers of \mathbf{k} with the help of the Gaussian formula

$$\int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')-it\hbar k^2/2M} = \frac{1}{(2\pi i\hbar/M)^{D/2}} e^{iM(\mathbf{x}-\mathbf{x}')^2/2\hbar t}. \quad (4.322)$$

If we define the momentum average with respect to this integral as

$$\langle f(\mathbf{k}) \rangle_k \equiv \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')-it\hbar k^2/2M} f(\mathbf{k}) \Big/ \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}(\mathbf{x}-\mathbf{x}')-it\hbar k^2/2M}, \quad (4.323)$$

we see that

$$\langle f(\mathbf{k}) \rangle_k = f(-i\nabla_{\mathbf{x}}) e^{iM(\mathbf{x}-\mathbf{x}')^2/2\hbar t}, \quad (4.324)$$

so that the expectation values of products of momenta are

$$\begin{aligned} \langle k_i \rangle_k &= -i\nabla_i e^{iM(\mathbf{x}-\mathbf{x}')^2/2\hbar t} = \kappa_i e^{iM(\Delta\mathbf{x})^2/2\hbar t}, & \kappa_i &\equiv \frac{M}{\hbar} \frac{(x-x')_i}{t}, \\ \langle k_i k_j \rangle_k &= i\nabla_i \nabla_j e^{iM(\mathbf{x}-\mathbf{x}')^2/2\hbar t} = \left(\kappa_i \kappa_j + \frac{M}{i\hbar t} \delta_{ij} \right) e^{iM(\Delta\mathbf{x})^2/2\hbar t}, \\ \langle k_i k_j k_k \rangle_k &= -\nabla_i \nabla_j \nabla_k e^{iM\Delta\mathbf{x}^2/2\hbar t} = \left[\kappa_i \kappa_j \kappa_k + \frac{M}{i\hbar t} (\delta_{ij} \kappa_k + \delta_{jk} \kappa_i + \delta_{ki} \kappa_j) \right] e^{iM(\Delta\mathbf{x})^2/2\hbar t}. \end{aligned} \quad (4.325)$$

The list can easily be continued using Leibnitz' chain rule of differentiation and the derivative $-i\nabla_i \kappa_j = \delta_{ij} M/i\hbar t$. A compact formula for the result is

$$\begin{aligned} \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle &= \frac{1}{(2\pi i\hbar/M)^{D/2}} \langle C(\mathbf{x}, \mathbf{k}, t) \rangle_q \\ &= \frac{1}{(2\pi i\hbar/M)^{D/2}} C(\mathbf{x}; -i\nabla_{\mathbf{x}}, t) e^{iM(\mathbf{x}-\mathbf{x}')^2/2\hbar t}. \end{aligned} \quad (4.326)$$

Our goal is to obtain the amplitude $\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle$ as a short-time expansion

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \frac{e^{iM(\Delta\mathbf{x})^2/2\hbar t}}{(2\pi i\hbar/M)^{D/2}} \sum_{n=0}^{\infty} t^n a_n(\mathbf{x}, \Delta\mathbf{x}). \quad (4.327)$$

The above \mathbf{k} -averages show, however, that the expectations of the coefficients of the expansion (4.321) contain powers of t up to t^n . These must be rearranged to find the power series (4.327). An explicit expression for the expansion coefficients $a_n(\mathbf{x}, \Delta\mathbf{x})$ is found by rescaling \mathbf{k} and introducing $\mathbf{q} \equiv \mathbf{k}\sqrt{t\hbar/M}$ and rewriting $C(\mathbf{x}; \mathbf{q}\sqrt{M/t\hbar}, t)$ as

$$C(\mathbf{x}; \mathbf{q}\sqrt{M/t\hbar}, t) = \left[e^{-it[-\hbar^2\nabla^2/2M + V(\mathbf{x}) - i\mathbf{q}\sqrt{i\hbar/Mt}\hbar\nabla]/\hbar} \right]_{\mathcal{Y}^n}, \quad (4.328)$$

where the symbol $[\dots]_{\mathcal{Y}^n}$ indicates that we have to drop all pure powers $V^n(x)$ in the n th expansion coefficients of the exponential. With this we can rewrite (4.319) as

$$\langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x}' \rangle = \frac{e^{iM(\Delta\mathbf{x})^2/2\hbar t}}{(2\pi i\hbar/M)^{D/2}} \left[e^{-\Delta\mathbf{x}^2/2} \langle C(\mathbf{x}, \mathbf{q}\sqrt{M/t\hbar}, t) \rangle_{\mathcal{q}} \right]_{\mathcal{Y}^n}, \quad (4.329)$$

where the \mathbf{q} -averages are obtained from formulas (4.325) in which M is set equal to $i\hbar t$. They are defined by the Gaussian integrals

$$\langle f(\mathbf{q}) \rangle_{\mathcal{q}} \equiv \int \frac{d^D q}{(2\pi)^D} f(\mathbf{q}) e^{i\mathbf{q}\Delta\mathbf{x} - q^2/2} \Big/ \int \frac{d^D q}{(2\pi)^D} e^{i\mathbf{q}\Delta\mathbf{x} - q^2/2}. \quad (4.330)$$

whose power series can be evaluated with the help of the integrals

$$\begin{aligned} \int \frac{d^D q}{(2\pi)^D} e^{-q^2/2} \{1, q_i q_j, q_{i_1} q_{i_2} q_{i_3} q_{i_4}, \dots, q_{i_1} q_{i_2} \dots q_{i_{2n-1}} q_{i_{2n}}, \dots\} \\ = \frac{1}{(2\pi)^{D/2}} \{1, \delta_{ij}, \delta_{i_1 i_2 i_3 i_4}, \dots, \delta_{i_1 i_2 \dots i_{2n-1} i_{2n}}, \dots\}. \end{aligned} \quad (4.331)$$

The results are the analogs of the equations in (4.325):

$$\begin{aligned} \langle q_i \rangle_{\mathcal{q}} &= -i\nabla_i e^{-(\Delta\mathbf{x})^2/2} = \Delta x_i e^{-(\Delta\mathbf{x})^2/2}, \\ \langle q_i q_j \rangle_{\mathcal{q}} &= i\nabla_i \nabla_j e^{-(\mathbf{x}-\mathbf{x}')^2/2} = (\Delta x_i \Delta x_j + \delta_{ij}) e^{-(\Delta\mathbf{x})^2/2}, \\ \langle q_i q_j q_k \rangle_{\mathcal{q}} &= -\nabla_i \nabla_j \nabla_k e^{iM\Delta\mathbf{x}^2/2} = [\Delta x_i \Delta x_j \Delta x_k + (\delta_{ij} \Delta x_k + \delta_{jk} \Delta x_i + \delta_{ki} \Delta x_j)] e^{-(\Delta\mathbf{x})^2/2}. \end{aligned} \quad (4.332)$$

Here $\delta_{i_1 i_2 \dots i_{2n-1} i_{2n}}$ are the so-called *contraction tensors* defined for $n > 2$ recursively by the relation

$$\delta_{i_1 \dots i_{2n}} = \delta_{i_1 i_2} \delta_{i_3 i_4 \dots i_{2n}} + \delta_{i_1 i_3} \delta_{i_2 i_4 \dots i_{2n}} + \dots + \delta_{i_1 i_{2n}} \delta_{i_2 i_3 \dots i_{2n-1}}. \quad (4.333)$$

With these formulas, the calculation of the diagonal expansion coefficients which have $\Delta\mathbf{x} = 0$ is quite simple. For the sake of generality we also allow for the presence of a vector potential via the minimal substitution law (2.644). In the operator language, where \mathbf{p} is represented by the differential operator $\hat{\mathbf{p}} = -i\hbar\nabla$ [recall (1.89), the derivatives ∇ in (4.328) must be replaced by the covariant derivatives $\mathbf{D} \equiv \nabla - i(e/c\hbar)\mathbf{A}$. The commutator of these derivatives is no longer zero but proportional to the magnetic field:

$$[D_i, D_j] = -i\epsilon_{ijk}(e/c\hbar)B_k \quad (4.334)$$

Expanding (4.328) up to second order in t we find

$$\begin{aligned} a_0 &= 1, \quad a_1 = 0, \\ a_2 &= \left\langle \frac{1}{2}(-\hat{H}^2 - V^2) - \frac{\hbar^2}{3!M} \left[\hat{H}(\mathbf{q}\mathbf{D})^2 + (\mathbf{q}\mathbf{D})\hat{H}(\mathbf{q}\mathbf{D}) + (\mathbf{q}\mathbf{D})^2\hat{H} \right] - \frac{\hbar^4}{4!M^2}(\mathbf{q}\mathbf{D})^4 \right\rangle_{\mathcal{q}}. \end{aligned} \quad (4.335)$$

Performing the momentum averages with the help of (4.332), a_2 becomes

$$a_2 = -\frac{1}{2}(\hat{H}^2 - V^2) - \frac{\hbar^2}{3!M} \left[\hat{H}\mathbf{D}^2 + \mathbf{D}\hat{H}\mathbf{D} + \mathbf{D}^2\hat{H} \right] - \frac{\hbar^4}{8M^2}(\mathbf{D}^4 + D_i D_j D_i D_j + D_i \mathbf{D}^2 D_i). \quad (4.336)$$

Inserting here $\hat{H} = -\hbar^2 \mathbf{D}^2/2M + V$, this takes the form

$$a_2 = -\frac{1}{2} \left[\left(\frac{\hbar^2 \mathbf{D}^2}{2M} \right)^2 - \frac{\hbar^2}{2M} (\mathbf{D}^2 V + V \mathbf{D}^2) \right] - \frac{\hbar^2}{3!M} \left[\hat{H} \mathbf{D}^2 + \mathbf{D} \hat{H} \mathbf{D} + \mathbf{D}^2 \hat{H} \right] - \frac{\hbar^4}{8M^2} (\mathbf{D}^4 + D_i D_j D_i D_j + D_i \mathbf{D}^2 D_i). \quad (4.337)$$

After some algebra this becomes

$$a_2 = \frac{\hbar^2}{12M} [\mathbf{D}^2 V(x) + V(x) \mathbf{D}^2] - \frac{\hbar^2}{6M} D_i V(x) D_i - \frac{\hbar^4}{48M^2} [D_i, D_j]^2, \quad (4.338)$$

where the derivative terms which have no functions of \mathbf{x} behind it vanish. In the absence of a magnetic field, a_2 reduces to

$$a_2 = \frac{\hbar^2}{12M} \nabla^2 V(x), \quad (4.339)$$

in agreement with the second expansion term in Eq. (4.258). A magnetic field \mathbf{B} orthogonal to the 12-plane adds to this a term

$$\Delta a_2^B = -\frac{\hbar^4}{48M^2} ([D_1, D_2]^2 + [D_2, D_1]^2) = \frac{\hbar^2}{24M^2} \left(\frac{e}{c} \right)^2 B^2. \quad (4.340)$$

This can be compared to the exact result in Eq. (2.668) where the diagonal amplitude has a unit exponential factor, and the small- t expansion is coming only from the Taylor series of the fluctuation factor $(\omega_L t/2)/\sin(\omega_L t/2)$. This starts out like $1 + \omega_L^2 t^2/24 = 1 + t^2 (\hbar^2/24M^2) (e/c)^2 B^2$, in agreement with the above magnetic term.

4.9.5 Local Density of States on a Circle

For future use, let us also calculate this determinant for x on a circle $x = (0, b)$, so that, as a side result, we obtain also the gradient expansion of the tracelog of the operator $(-\partial_\tau^2 + \omega^2(\tau))$ at a finite temperature. For this we recall that for a τ -independent frequency, the starting point is Eq. (2.558), according to which the tracelog of the operator $(-\partial_\tau^2 + \omega^2)$ with periodic boundary conditions in $\tau \in (0, \hbar\beta)$ is given by

$$F_\omega = -\frac{\hbar}{\sqrt{\pi}} \int_0^\infty \frac{d\tau}{\tau} \tau^{-1/2} \left[1 + 2 \sum_{n=1}^\infty e^{-(n\hbar\beta)^2/4\tau} \right] e^{-\tau\omega^2}. \quad (4.341)$$

The first term is the zero-temperature expression, the second comes from the Poisson summation formula and gives the finite-temperature effects. In the first (classical) term of the density (4.253), the factor $1/\sqrt{2\pi\hbar\tau/M}$ came from the integral over the Boltzmann factor involving the kinetic energy $\int_{-\infty}^\infty (dk/2\pi) e^{-\tau\hbar k^2/2M}$. For periodic boundary conditions in $x \in (0, b)$, this is changed to $(1/b) \sum_m e^{-\tau\hbar k_m^2/2M}$, where $k_m = 2\pi m/b$. By Poisson's formula (1.205), this can be replaced by the integral and an auxiliary sum

$$\frac{1}{b} \sum_m e^{-\tau\hbar k_m^2/2M} = \sum_{n=-\infty}^\infty \int_{-\infty}^\infty \frac{dk}{2\pi} e^{-\tau\hbar k^2/2M + ibkn} = \frac{1}{\sqrt{2\pi\hbar\tau/M}} \sum_{n=-\infty}^\infty e^{-n^2 M b^2/2\hbar\tau}. \quad (4.342)$$

If the sum is inserted into the integral (4.253), we obtain the density $\rho(E; x)$ on a circle of circumference b , with the classical contribution

$$\rho_{\text{cl}}(b, E; x) = 2 \int_0^\infty \frac{d\tau}{2\pi\hbar} \sum_{n=-\infty}^\infty \frac{e^{-n^2 M b^2/2\hbar\tau - \tau[E - V(x)]/\hbar}}{(2\pi\hbar\tau/M)^{1/2}}. \quad (4.343)$$

The $n = 0$ -term in the sum leads back to the original expression (4.253) on an infinite x -axis. The τ -integrals are now done with the help of formula (2.559) which yields, due to $K_\nu(z) = K_{-\nu}(z)$,

$$\int_0^\infty \frac{d\tau}{\tau} \tau^\nu e^{-n^2 M b^2 / 2\hbar\tau - [E - V(x)]\tau/\hbar} = 2 \left[\frac{nM b}{p(E; x)} \right]^\nu K_\nu(np(E; x)b/\hbar), \quad (4.344)$$

and we obtain, instead of (4.254),

$$\rho_{\text{cl}}(b, E; x) = \frac{1}{\pi\hbar} \frac{1}{\sqrt{2\pi\hbar/M}} 2 \sum_{n=0}^\infty \left[\frac{nM b}{p(E; x)} \right]^{1/2} K_{1/2}(np(E; x)b/\hbar). \quad (4.345)$$

Inserting $K_{1/2}(z) = \sqrt{\pi/2z} e^{-z}$ [recall (2.561)], this becomes

$$\rho_{\text{cl}}(b, E; x) = \frac{M}{\pi\hbar} \frac{1}{p(E; x)} \left(1 + 2 \sum_{n=1}^\infty e^{-np(E; x)b/\hbar} \right). \quad (4.346)$$

The sum $\sum_{n=1}^\infty \alpha^n$ is equal to $\alpha/(1 - \alpha)$, so that we obtain

$$\rho_{\text{cl}}(b, E; x) = \frac{M}{\pi\hbar} \frac{\coth[p(E; x)b/2\hbar]}{p(E; x)} = \frac{M}{\pi\hbar} \frac{\coth \sqrt{2M[E - V(x)]} b/2\hbar}{\sqrt{2M[E - V(x)]}}. \quad (4.347)$$

For $b \rightarrow \infty$, this reduces to the previous density (4.254).

If we include the higher powers of τ in (4.253), we obtain the generalization of expression (4.255):

$$\rho(b, E; x) = \left\{ 1 - \frac{\hbar^2}{12M} V''(x) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [V'(x)]^2 \frac{d^3}{dV^3} + \dots \right\} \rho_{\text{cl}}(b, E; x). \quad (4.348)$$

The tracelog is obtained by integrating this over $dE \log E$ from $V(x)$ to infinity. The integral diverges, and we must employ analytic regularization. We proceed as in (4.288), by using the real-time version of (4.343) and rewriting $\log E$ as an integral $-\int_0^\infty (dt'/t') e^{-iEt'/\hbar}$, so that the leading term in (4.348) is given by

$$[\text{Tr} \log \hat{H}]_{\text{cl}} = - \int_0^b dx \int_{-\infty}^\infty dE \int_{-\infty}^\infty \frac{dt}{2\pi\hbar} \sum_{n=-\infty}^\infty \frac{e^{-in^2 M b^2 / 2\hbar t + it[E - V(x)]/\hbar}}{(2\pi i \hbar t / M)^{1/2}} \int_0^\infty \frac{dt'}{t'} e^{-iEt'/\hbar}. \quad (4.349)$$

The integral over E leads now to

$$[\text{Tr} \log \hat{H}]_{\text{cl}} = - \sum_{n=-\infty}^\infty \int_0^b dx \int_0^\infty \frac{dt}{t} \frac{1}{(2\pi i \hbar t / M)^{1/2}} e^{-in^2 M b^2 / 2\hbar t - itV(x)/\hbar}. \quad (4.350)$$

Deforming again the contour of integration by the substitution $t = -i\tau$, creating the τ^{-1} in the denominator by an integration over $V(x)/\hbar$, we see that

$$\begin{aligned} [\text{Tr} \log \hat{H}]_{\text{cl}} &= -\pi \int_0^b dx \int_{V(x)}^\infty dV \rho_{\text{cl}}(b, E; x) \Big|_{E=V(x) \rightarrow V} \\ &= \pi \int_0^b dx \int_{V(x)}^\infty \frac{dV}{E_b} \frac{1}{4\pi b} \frac{\coth \frac{1}{2} \sqrt{V/E_b}}{\frac{1}{2} \sqrt{V/E_b}}, \end{aligned} \quad (4.351)$$

where $E_b \equiv \hbar/2M b^2$ is the energy associated with the length b . The integration over V produces a factor \hbar/τ in the integrand.

Thus we obtain

$$\mathrm{Tr} \log \hat{H} = \int_0^b dx \left\{ 1 + \frac{\hbar^2}{24M} [V'(x)]^2 \frac{d^3}{dV^3} + \dots \right\} \frac{2}{b} \log \left\{ 2 \sinh \left[\frac{1}{2} \sqrt{\frac{V(x)}{E_b}} \right] \right\}. \quad (4.352)$$

For $M = \hbar^2/2$, this give us the finite- b correction to formula (4.314). Replacing x by the Euclidean time τ , b by $\hbar\beta$, and $V(x)$ by the time-dependent square frequency $\omega^2(\tau)$, we obtain the gradient expansion

$$\mathrm{Tr} \log [-\partial_\tau^2 + \omega^2(\tau)] = \int_0^{\hbar\beta} d\tau \left\{ 1 + \frac{[\partial_\tau \omega^2(\tau)]^2}{12} \partial_{\omega^2}^3 + \dots \right\} \frac{2}{\hbar\beta} \log \left[2 \sinh \frac{\hbar\beta\omega(\tau)}{2} \right]. \quad (4.353)$$

4.9.6 Quantum Corrections to Bohr-Sommerfeld Approximation

The expansion (4.315) can be used to obtain a higher-order expansion of the density of states $\rho(E)$, thereby extending Eq. (4.257). For this we recall Eq. (1.595) according to which we can calculate the exact density of states from the formula

$$\rho(E) = -\frac{1}{\pi} \partial_E \mathrm{Im} \mathrm{Tr} \log \{ -\partial_x^2 + [V(x) - E] \}. \quad (4.354)$$

Integrating this over the energy yields, according to Eq. (1.596), the number of states times π , and thus the simple *exact* quantization condition for a nondegenerate one-dimensional system:

$$-\mathrm{Im} \mathrm{Tr} \log \{ -\partial_x^2 + [V(x) - E] \} = \pi(n + 1/2). \quad (4.355)$$

By comparison with Eq. (4.209) we may define a fully quantum corrected version of the classical eikonal:

$$S_{\mathrm{qc}}(E) = -2\hbar \mathrm{Im} \mathrm{Tr} \log \{ -\partial_x^2 + [V(x) - E] \}. \quad (4.356)$$

The semiclassical expansion of this can be obtained from our earlier result (4.315) by replacing $V(x) \rightarrow V(x) - E$, so that $\sqrt{V(x)} \rightarrow -i\sqrt{E - V(x)}$, yielding

$$S_{\mathrm{qc}}(E) = 2 \int dx \sqrt{E - V(x)} \left\{ 1 + \hbar^2 \left[\frac{5V'^2}{32(E-V)^3} + \frac{V''}{8(E-V)^2} \right] - \hbar^4 \left[\frac{1105V'^4}{2048(E-V)^6} + \frac{221V'^2V''}{256(E-V)^5} + \frac{19V''^2}{128(E-V)^4} + \frac{7V'V^{(3)}}{32(E-V)^4} + \frac{V^{(4)}}{32(E-V)^3} + \dots \right] \right\}. \quad (4.357)$$

The first term in the expansion corresponds to the Bohr-Sommerfeld approximation (4.27), the remaining ones yield the quantum corrections. The integrand agrees, of course, with the WKB expansion of the eikonal (4.14) after inserting the expansion terms S_0, S_1, \dots , obtained by integrating the relations (4.20) over the functions $q_0(x), q_1(x), \dots$ of Eq. (4.18).

Using Eq. (4.354) we obtain from $S_{\mathrm{qc}}(E)$ the density of states

$$\rho(E) = \frac{1}{2\pi\hbar} S_{\mathrm{qc}}(E) = \frac{1}{2\pi\hbar} \int dx \frac{1}{\sqrt{E - V}} \left\{ 1 - \hbar^2 \left[\frac{25V'^2}{32(E-V)^3} + \frac{3V''}{8(E-V)^2} \right] + \hbar^3 \left[\frac{12155V'^4}{2048(E-V)^6} + \frac{1989V'^2V''}{256(E-V)^5} + \frac{133V''^2}{128(E-V)^4} + \frac{49V'V^{(3)}}{32(E-V)^4} + \frac{5V^{(4)}}{32(E-V)^3} \right] \right\}. \quad (4.358)$$

Let us calculate the quantum corrections to the semiclassical energies for a purely quartic potential $V(x) = gx^4/4$, where the integral over the first term in (4.357) between the turning points $\pm x_E = \pm(4E/g)^{1/4}$ gave the Bohr-Sommerfeld approximation (4.33). The integrals of the higher terms in (4.357) are divergent, but can be calculated in analytically regularized form using once more the integral formula (4.34). This extends the Bohr-Sommerfeld equation $\nu(E) = n + 1/2$ to the exact equation $N(E) \equiv S_{qc}/2\pi\hbar = n + 1/2$ [recall (1.596)]. If we express $N(E)$ in terms of $\nu(E)$ defined in Eq. (4.33) rather than E , we obtain the expansion

$$N(\nu) = \nu - \frac{1}{12\pi\nu} + \frac{11\pi^2}{10368\Gamma^8(\frac{3}{4})\nu^3} + \frac{4697\pi}{1866240\Gamma^8(\frac{3}{4})\nu^5} - \frac{390065\pi^4}{501645312\Gamma^{16}(\frac{3}{4})\nu^7} - \frac{53352893\pi^3}{7739670528\Gamma^{16}(\frac{3}{4})\nu^9} + \dots = n + 1/2. \tag{4.359}$$

The function is plotted in Fig. 4.359 for increasing orders in y . Given a solution $\nu^{(n)}$ of this equation, we obtain the energy $E^{(n)}$ from Eq. (4.35) with

$$\kappa^{(n)} = [\nu^{(n)}3\Gamma(3/2)^2/2\sqrt{\pi}]^{4/3}. \tag{4.360}$$

For large n , where $\nu^{(n)} \rightarrow n$, we recover the Bohr-Sommerfeld result (4.36). We can invert the

Figure 4.1 Determination of energy eigenvalues $E^{(n)}$ for purely quartic potential $gx^4/4$ in semiclassical expansion. The intersections of $N(\nu)$ with the horizontal lines yield $\nu^{(n)}$, from which $E^{(n)}$ is obtained via Eqs. (4.360) and (4.35). The increasing dash lengths show the expansions of $N(\nu)$ to increasing orders in ν . For the ground state with $n = 0$, the expansion is too divergent to give improvements to the lowest approximation without resumming the series; Right: Comparison between exact and semiclassical energies. The plot is for $\log[E^{(n)}/E_{BS}^{(n)} - 1]$.

series (4.359) and obtain

$$\nu^{(n)} = (n + \frac{1}{2}) \left[1 + \frac{0.026525823}{(n + \frac{1}{2})^2} - \frac{0.002762954}{(n + \frac{1}{2})^4} - \frac{0.001299177}{(n + \frac{1}{2})^6} + \frac{0.003140091}{(n + \frac{1}{2})^8} + \frac{0.007594497}{(n + \frac{1}{2})^{10}} + \dots \right]. \tag{4.361}$$

The results are compared with the exact ones in Table 4.1, which approach rapidly the Bohr-Sommerfeld limit $0.688\ 253\ 702\dots$ The approach is illustrated in the right-hand part of Fig. 4.1 where $\log[\nu^{(n)}/(n + \frac{1}{2})^{4/3} - 1] = \log[E^{(n)}/E_{BS}^{(n)} - 1]$ is plotted once for the exact values and once for the semiclassical expansion in Fig. 4.1. The second excited states is very well represented by the series. Although the series is only asymptotic, the results for higher n are excellent. For a detailed study of the convergence properties of the semiclassical expansion see Ref. [5].

Table 4.1 Particle energies in purely anharmonic potential $gx^4/4$ for $n = 0, 2, 4, 6, 8, 10$.

n	$E^{(n)}/(g\hbar/4M^2)^{1/3}$	$\kappa^{(n)}/2(n+1/2)^{4/3}$

Having obtained the quantum-corrected eikonal $S_{\text{qc}}(E)$ we can write down a quantum-corrected partition function replacing the classical eikonal $S(E)$ in Eq. (4.236):

$$Z_{\text{qc}}(E) = t_{\text{qc}}(E) \frac{1}{P_{\text{qc}}(1)^{1/2}} \frac{e^{iS_{\text{qc}}(E)-i\pi\nu/2}}{1 - e^{iS_{\text{qc}}(E)-i\pi\nu/2}}. \quad (4.362)$$

where $t_{\text{qc}}(E) \equiv S'_{\text{qc}}(E)$ [compare (4.198)], and $P_{\text{qc}}(1)^{1/2}$ is the quantum-corrected determinant (4.234) whose calculation will require extra work.

4.10 Thomas-Fermi Model of Neutral Atoms

The density of states calculated in the last section forms the basis for the *Thomas-Fermi model* of neutral atoms. If an atom has a large nuclear charge Z , most of the electrons move in orbits with large quantum numbers. For $Z \rightarrow \infty$, we expect them to be described by semiclassical limiting formulas, which for decreasing values of Z require quantum corrections. The largest quantum correction is expected for electrons near the nucleus which must be calculated separately.

4.10.1 Semiclassical Limit

Filling up all negative energy states with electrons of both spin directions produces some local particle density $n(\mathbf{x})$, which is easily calculated from the classical local density (4.217) over all negative energies, yielding the *Thomas-Fermi density of states*

$$\rho_{\text{cl}}^{(-)}(\mathbf{x}) = \int_{V(\mathbf{x})}^0 dE \rho_{\text{cl}}(E; \mathbf{x}) = \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \frac{1}{\Gamma(D/2 + 1)} [-V(\mathbf{x})]^{D/2}. \quad (4.363)$$

This expression can also be obtained directly from the phase space integral over the accessible free-particle energies. At each point \mathbf{x} , the electrons occupy all levels up to a *Fermi energy*

$$E_F = \frac{p_F(\mathbf{x})^2}{2M} + V(\mathbf{x}). \quad (4.364)$$

The associated local *Fermi momentum* is equal to the local momentum function (4.215) at $E = E_F$:

$$p_F(\mathbf{x}) = p(E_F; \mathbf{x}) = \sqrt{2M[E_F - V(\mathbf{x})]}. \quad (4.365)$$

The electrons fill up the entire Fermi sphere $|\mathbf{p}| \leq p_F(\mathbf{x})$:

$$\rho_{\text{cl}}^{(-)}(\mathbf{x}) = \int_{|\mathbf{p}| \leq p_F(\mathbf{x})} \frac{d^D p}{(2\pi\hbar)^D} = \frac{1}{(2\pi\hbar)^D} S_D \int_0^{p_F(\mathbf{x})} dp p^{D-1} = \frac{1}{(2\pi\hbar)^D} \frac{2\pi^{D/2}}{\Gamma(D/2)} \frac{p_F^D(\mathbf{x})}{D}. \quad (4.366)$$

For neutral atoms, the Fermi energy is zero and we recover the density (4.363).

By occupying each state of negative energy twice, we find the classical electron density

$$n(\mathbf{x}) = 2\rho_{\text{cl}}^{(-)}(\mathbf{x}). \quad (4.367)$$

The potential energy density associated with the levels of negative energy is obviously

$$E_{\text{pot TF}}^{(-)}(\mathbf{x}) = V(\mathbf{x})\rho_{\text{cl}}^{(-)}(\mathbf{x}) = - \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \frac{1}{\Gamma(D/2 + 1)} [-V(\mathbf{x})]^{D/2+1}. \quad (4.368)$$

To find the kinetic energy density we integrate

$$\begin{aligned} E_{\text{kin TF}}^{(-)}(\mathbf{x}) &= \int_{V(\mathbf{x})}^0 dE [E - V(\mathbf{x})] \rho_{\text{cl}}(E; \mathbf{x}) \\ &= \frac{D/2}{D/2 + 1} \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \frac{1}{\Gamma(D/2 + 1)} [-V(\mathbf{x})]^{D/2+1}. \end{aligned} \quad (4.369)$$

As in the case of the density of states (4.366), this expression can be obtained directly from the phase space integral over the free-particle energies

$$E_{\text{kin TF}}^{(-)}(\mathbf{x}) = \int_{|\mathbf{p}| \leq p_F(\mathbf{x})} \frac{d^D p}{(2\pi\hbar)^D} \frac{p^2}{2M}. \quad (4.370)$$

Performing the momentum integral on the right-hand side yields the energy density

$$E_{\text{kin TF}}^{(-)}(\mathbf{x}) = \frac{1}{(2\pi\hbar)^D} S_D \frac{1}{2M} \int_0^{p_F(\mathbf{x})} dp p^{D+1} = \frac{1}{(2\pi\hbar)^D} \frac{S_D}{D+2} \frac{p_F^{D+2}(\mathbf{x})}{2M}, \quad (4.371)$$

in agreement with (4.369). The sum of the two is the Thomas-Fermi energy density

$$\begin{aligned} E_{\text{TF}}^{(-)}(\mathbf{x}) &= \int_{V(\mathbf{x})}^0 dE E \rho_{\text{cl}}(E; \mathbf{x}) \\ &= - \frac{1}{D/2 + 1} \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \frac{1}{\Gamma(D/2 + 1)} [-V(\mathbf{x})]^{D/2+1}. \end{aligned} \quad (4.372)$$

The three energies are related by

$$E_{\text{TF}}^{(-)}(\mathbf{x}) = - \frac{1}{D/2} E_{\text{kin TF}}^{(-)}(\mathbf{x}) = \frac{1}{D/2 + 1} E_{\text{pot TF}}^{(-)}(\mathbf{x}). \quad (4.373)$$

Note that the Thomas-Fermi model can also be applied to ions.¹⁴ Then the energy levels are filled up to a nonzero Fermi energy E_F , so that the density of

¹⁴H.J. Brudner and S. Borowitz, Phys. Rev. 120, 2054 (1960).

states (4.363) and the kinetic energy (4.369) have $-V$ replaced by $E_F - V$. This follows immediately from the representations (4.366) and (4.370) where the right-hand sides depend only on $p_F(\mathbf{x}) = \sqrt{2M[E_F - V(\mathbf{x})]}$. In the potential energy (4.368), the expression $(-V)^{D/2+1}$ is replaced by $(-V)(E_F - V)^{D/2}$, whereas in the Thomas-Fermi energy density (4.372) it becomes $(1 - E_F \partial / E_F)(E_F - V)^{D/2+1}$.

4.10.2 Self-Consistent Field Equation

The total electrostatic potential energy $V(\mathbf{x})$ caused by the combined charges of the nucleus and the electron cloud is found by solving the Poisson equation

$$\nabla^2 V(\mathbf{x}) = 4\pi e^2 [Z\delta^{(3)}(\mathbf{x}) - n(\mathbf{x})] \equiv 4\pi e^2 [n_C(\mathbf{x}) - n(\mathbf{x})]. \quad (4.374)$$

The nucleus is treated as a point charge which by itself gives rise to the Coulomb potential

$$V_C(\mathbf{x}) = -\frac{Ze^2}{r}. \quad (4.375)$$

Recall that in these units $e^2 = \alpha \hbar c$, where α is the dimensionless fine-structure constant (1.505). A single electron near the ground state of this potential has orbits with diameters of the order na_H/Z , where n is the principal quantum number and a_H the *Bohr radius* of the hydrogen atom, which will be discussed in detail in Chapter 13. The latter is expressed in terms of the electron charge e and mass M as

$$a_H = \frac{\hbar^2}{Me^2} = \frac{1}{\alpha} \lambda_M^C. \quad (4.376)$$

This equation implies that a_H is about 137 times larger than the *Compton wavelength* of the electron

$$\lambda_M^C \equiv \hbar/Mc \approx 3.861\,593\,23 \times 10^{-13} \text{ cm}. \quad (4.377)$$

It is convenient to describe the screening effect of the electron cloud upon the Coulomb potential (4.375) by a multiplicative dimensionless function $f(\mathbf{x})$. Restricting our attention to the ground state, which is rotationally symmetric, we shall write the solution of the Poisson equation (4.374) as

$$V(\mathbf{x}) = -\frac{Ze^2}{r} f(r). \quad (4.378)$$

At the origin the function $f(r)$ is normalized to unity,

$$f(0) = 1, \quad (4.379)$$

to ensure that the nuclear charge is not changed by the electrons.

It is useful to introduce a length scale of the electron cloud

$$a_{\text{TF}} = \frac{1}{e^2 Z^{1/3}} \frac{2\pi\hbar^2}{M} \left[\frac{\Gamma(5/2)}{2 \cdot 4\pi} \right]^{2/3} = \frac{1}{2} \left(\frac{3\pi}{4} \right)^{2/3} \frac{a_H}{Z^{1/3}} \approx 0.8853 \frac{a_H}{Z^{1/3}}, \quad (4.380)$$

which is larger than the smallest orbit a_H/Z by roughly a factor $Z^{2/3}$. All length scales will now be specified in units of a_{TF} , i.e., we set

$$r = a_{\text{TF}} \xi. \quad (4.381)$$

In these units, the electron density (4.367) becomes simply

$$n(\mathbf{x}) = -\frac{(2Ze^2M)^{3/2}}{3\pi^2\hbar^3} \left[\frac{f(\xi)}{a_{\text{TF}}\xi} \right]^{3/2} = \frac{Z}{4\pi a_{\text{TF}}^3} \left[\frac{f(\xi)}{\xi} \right]^{3/2}. \quad (4.382)$$

The left-hand side of the Poisson equation (4.374) reads

$$\nabla^2 V(\mathbf{x}) = \frac{1}{r} \frac{d}{dr^2} rV(\mathbf{x}) = -\frac{Ze^2}{a_{\text{TF}}^3} \frac{1}{\xi} f''(\xi), \quad (4.383)$$

so that we obtain the self-consistent *Thomas-Fermi equation*

$$f''(\xi) = \frac{1}{\sqrt{\xi}} f^{3/2}(\xi), \quad \xi > 0. \quad (4.384)$$

This equation ensures that the volume integral over the above electron density is equal to Z . The condition $\xi > 0$ excludes the nuclear charge from the equation, whose correct magnitude is incorporated by the initial condition (4.379).

Figure 4.2 Solution for screening function $f(\xi)$ in Thomas-Fermi model.

The differential equation (4.384) is solved numerically by the function shown in Fig. 4.2. Near the origin, it starts out like

$$f(\xi) = 1 - s\xi + \dots, \quad (4.385)$$

with a slope

$$s \approx 1.58807. \quad (4.386)$$

The higher powers of the expansion can be calculated recursively as shown in Appendix 4C. They are, however, useless for an evaluation of the function since the expansion is divergent. A technique for evaluating such expansions will be developed in Chapter 5.

For large ξ , the function goes to zero like

$$f(\xi) \approx \frac{144}{\xi^3}. \quad (4.387)$$

This power falloff is a weakness of the model since the true screened potential should fall off exponentially fast. The right-hand side by itself happens to be an exact solution of (4.384), but does not satisfy the desired boundary condition $f(0) = 1$.

4.10.3 Energy Functional of Thomas-Fermi Atom

Let us derive an energy functional whose functional extremization yields the Thomas-Fermi equation (4.384). First, there is the kinetic energy of the spin-up and spin-down electrons in a potential $V(\mathbf{x})$. It is given by the volume integral over twice the Thomas-Fermi expression (4.369):

$$E_{\text{kin}}^{(-)} = 2 \frac{3}{5} \left(\frac{M}{2\pi\hbar^2} \right)^{3/2} \frac{1}{\Gamma(5/2)} \int d^3x [-V(\mathbf{x})]^{5/2}. \quad (4.388)$$

This can be expressed in terms of the electron density (4.367) as

$$E_{\text{kin}}^{(-)} = \frac{3}{5} \kappa \int d^3x n^{5/3}(\mathbf{x}), \quad (4.389)$$

where

$$\kappa \equiv \frac{\hbar}{2M} (3\pi^2)^{2/3}. \quad (4.390)$$

The potential energy

$$E_{\text{pot}}^{(-)} = \int d^3x V(\mathbf{x})n(\mathbf{x}) \quad (4.391)$$

is related to $E_{\text{kin}}^{(-)}$ via relation (4.373) as

$$E_{\text{pot}}^{(-)} = -\frac{5}{3} E_{\text{kin}}^{(-)}, \quad (4.392)$$

and the total electron energy in the potential $V(\mathbf{x})$ is

$$E_e^{(-)} = E_{\text{kin}}^{(-)} + E_{\text{pot}}^{(-)} = \frac{2}{5} E_{\text{pot}}^{(-)}. \quad (4.393)$$

We now observe that if we consider the energy as a functional of an *arbitrary* density $n(\mathbf{x})$,

$$E_e^{(-)} = \mathcal{E}_e[n] \equiv \frac{3}{5} \kappa \int d^3x n^{5/3}(\mathbf{x}) + \int d^3x V(\mathbf{x})n(\mathbf{x}), \quad (4.394)$$

the physical particle density (4.367) constitutes a minimum of the functional, which satisfies $\kappa n^{2/3}(\mathbf{x}) = -V(\mathbf{x})$. In the Thomas-Fermi atom, $V(\mathbf{x})$ on the right-hand side of (4.394) is, of course, the nuclear Coulomb potential, i.e.,

$$E_{\text{pot}}^{(-)} = E_C^{(-)} \equiv \int d^3x V_C(\mathbf{x}) n(\mathbf{x}). \quad (4.395)$$

The energy $E_e^{(-)}$ has to be supplemented by the energy due to the Coulomb repulsion between the electrons

$$E_{ee}^{(-)} = \mathcal{E}_{ee}[n] = \frac{e^2}{2} \int d^3x d^3x' n(\mathbf{x}) \frac{1}{|\mathbf{x} - \mathbf{x}'|} n(\mathbf{x}'). \quad (4.396)$$

The physical energy density should now be obtained from the minimum of the combined energy functional

$$\mathcal{E}_{\text{tot}}[n] = \frac{3}{5}\kappa \int d^3x n^{5/3}(\mathbf{x}) + \int d^3x V_C(\mathbf{x}) n(\mathbf{x}) + \frac{e^2}{2} \int d^3x d^3x' n(\mathbf{x}) \frac{1}{|\mathbf{x} - \mathbf{x}'|} n(\mathbf{x}'). \quad (4.397)$$

Since we are not very familiar with extremizing nonlocal functionals, it will be convenient to turn this into a local functional. This is done as follows. We introduce an auxiliary local field $\varphi(\mathbf{x})$ and rewrite the interaction term as

$$\mathcal{E}_{ee}[n, \varphi] = \mathcal{E}_\varphi[n, \varphi] - \mathcal{E}_{\varphi\varphi}[\varphi] \equiv \int d^3x \varphi(\mathbf{x}) n(\mathbf{x}) - \frac{1}{8\pi e^2} \int d^3x \nabla \varphi(\mathbf{x}) \nabla \varphi(\mathbf{x}). \quad (4.398)$$

Extremizing this in $\varphi(\mathbf{x})$, under the assumption of a vanishing $\varphi(\mathbf{x})$ at spatial infinity, yields the electric potential of the electron cloud

$$\nabla^2 \varphi(\mathbf{x}) = -4\pi e^2 n(\mathbf{x}), \quad (4.399)$$

which is the same as (4.374), but without the nuclear point charge at the origin. Inserting this into (4.398) we reobtain precisely to the repulsive electron-electron interaction energy (4.396).

Replacing the last term in (4.397) by the functional (4.398), we obtain a total energy functional $\mathcal{E}_{\text{tot}}[n, \varphi]$, for which it is easy to find the extremum with respect to $n(\mathbf{x})$. This lies at

$$\kappa n^{2/3}(\mathbf{x}) = -V(\mathbf{x}), \quad (4.400)$$

where

$$V(\mathbf{x}) = V_C(\mathbf{x}) + \varphi(\mathbf{x}) \quad (4.401)$$

is the combined Thomas-Fermi potential of the nucleus and the electron cloud solving the Poisson equation (4.374).

If the extremal density (4.400) is inserted into the total energy functional $\mathcal{E}_{\text{tot}}[n, \varphi]$, we may use the relation (4.392) to derive the following functional of $\varphi(\mathbf{x})$:

$$\mathcal{E}_{\text{tot}}[\varphi] = -\frac{2}{5} \int d^3x V(\mathbf{x}) n(\mathbf{x}) + \frac{1}{8\pi e^2} \int d^3x \varphi(\mathbf{x}) \nabla^2 \varphi(\mathbf{x}). \quad (4.402)$$

When extremizing this expression with respect to $\varphi(\mathbf{x})$ we must remember that $V(\mathbf{x}) = V_C(\mathbf{x}) + \varphi(\mathbf{x})$ is also present in $n(\mathbf{x})$ with a power 3/2. The extremum lies therefore again at a field satisfying the Poisson equation (4.399).

4.10.4 Calculation of Energies

We now proceed to calculate explicitly the energies occurring in Eq. (4.402). They turn out to depend only on the slope of the screening function $f(\xi)$ at the origin. Consider first $E_{\text{pot}}^{(-)}$. The common prefactor appearing in all energy expressions can be expressed in terms of the Thomas-Fermi length scale a_{TF} of Eq. (4.380) as

$$2 \frac{M^{3/2}}{(2\pi\hbar)^{3/2}} \frac{4\pi}{\Gamma(5/2)} e^3 = \frac{Z^{-1/2}}{a_{\text{TF}}^{3/2}}. \quad (4.403)$$

We therefore obtain the simple energy integral involving the screening function $f(\xi)$:

$$E_{\text{pot}}^{(-)} = -\frac{Z^2 e^2}{a} \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{5/2}(\xi). \quad (4.404)$$

The interaction energy between the electrons at the extremal $\varphi(\mathbf{x})$ satisfying (4.399) becomes simply

$$E_{\text{ee}}^{(-)} = \frac{1}{2} \int d^3x n(\mathbf{x}) \varphi(\mathbf{x}), \quad (4.405)$$

which can be rewritten as

$$E_{\text{ee}}^{(-)} = \frac{1}{2} \int d^3x n(\mathbf{x}) [V(\mathbf{x}) - V_{\text{C}}(\mathbf{x})] = \frac{1}{2} E_{\text{pot}}^{(-)} - \frac{1}{2} E_{\text{C}}^{(-)}. \quad (4.406)$$

Inserting this into (4.402) we find the alternative expression for the total energy

$$E_{\text{tot}}^{(-)} = \frac{2}{5} E_{\text{pot}}^{(-)} - E_{\text{ee}}^{(-)} = -\frac{1}{10} E_{\text{pot}}^{(-)} + \frac{1}{2} E_{\text{C}}^{(-)}. \quad (4.407)$$

The energy $E_{\text{C}}^{(-)}$ of the electrons in the Coulomb potential is evaluated as follows. Replacing $n(\mathbf{x})$ by $-\nabla^2 \varphi(\mathbf{x})/4\pi e^2$, we have, after two partial integrations with vanishing boundary terms and recalling (4.374),

$$E_{\text{C}}^{(-)} = -\frac{1}{4\pi e^2} \int d^3x \varphi(\mathbf{x}) \nabla^2 V_{\text{C}}(\mathbf{x}) = -\int d^3x \varphi(\mathbf{x}) n_{\text{C}}(\mathbf{x}). \quad (4.408)$$

Now, since

$$\varphi(\mathbf{x}) = V(\mathbf{x}) - V_{\text{C}}(\mathbf{x}) = -\frac{Ze^2}{r} [f(\xi) - 1], \quad n_{\text{C}} = Z\delta^{(3)}(\mathbf{x}), \quad (4.409)$$

we see that the Coulomb energy $E_{\text{C}}^{(-)}$ depends only on $\varphi(\mathbf{0})$, which can be expressed in terms of the negative slope (4.386) of the function $f(\xi)$ as:

$$\varphi(\mathbf{0}) = \frac{Ze^2}{a} s. \quad (4.410)$$

Thus we obtain

$$E_{\text{C}}^{(-)} = -\frac{Z^2 e^2}{a} s. \quad (4.411)$$

We now turn to the integral associated with the potential energy in Eq. (4.404):

$$I[f] = \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{5/2}(\xi). \quad (4.412)$$

By a trick it can again be expressed in terms of the slope parameter s . We express the energy functional (4.402) in terms of the screening function $f(\xi)$ as

$$\mathcal{E}_{\text{tot}}[\varphi] = -\frac{Z^2 e^2}{a_{\text{TF}}} \varepsilon[f], \quad (4.413)$$

with the dimensionless functional

$$\varepsilon[f] \equiv \frac{2}{5} I[f] + \frac{1}{2} J[f] = \int_0^\infty d\xi \left\{ \frac{2}{5} \frac{1}{\sqrt{\xi}} f^{5/2}(\xi) - \frac{1}{2} [f(\xi) - 1] f''(\xi) \right\}. \quad (4.414)$$

The second integral can also be rewritten as

$$J[f] = \int_0^\infty d\xi [f'(\xi)]^2. \quad (4.415)$$

This follows from a partial integration

$$J[f] = - \int_0^\infty d\xi [f(\xi) - 1] f''(\xi) = \int_0^\infty d\xi [f'(\xi)]^2 - [f(\xi) - 1] f'(\xi) \Big|_0^\infty, \quad (4.416)$$

inserting the boundary condition $f(\xi) - 1 = 0$ at $\xi = 0$ and $f'(\xi) = 0$ at $\xi = \infty$.

We easily verify that the Euler-Lagrange equation following from $\varepsilon[f]$ is the Thomas-Fermi differential equation (4.384).

As a next step in calculating the integrals I and J , we make use of the fact that under a scaling transformation

$$f(\xi) \rightarrow \bar{f}(\xi) = f(\lambda\xi), \quad (4.417)$$

the functional $\varepsilon[f]$ goes over into

$$\varepsilon_\lambda[f] = \frac{2}{5} \lambda^{-1/2} I[f] + \frac{1}{2} \lambda J[f]. \quad (4.418)$$

This must be extremal at $\lambda = 1$, from which we deduce that for $f(\xi)$ satisfying the differential equation (4.384):

$$I[f] = \frac{5}{2} J[f]. \quad (4.419)$$

This relation permits us to express the integral J in terms of the slope of $f(\xi)$ at the origin. For this we separate the two terms in (4.416), and replace $f''(\xi)$ via the Thomas-Fermi differential equation (4.384) to obtain

$$J = - \int_0^\infty d\xi f(\xi) f''(\xi) + \int_0^\infty d\xi f''(\xi) = - \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{5/2}(\xi) - f'(0) = -I + s. \quad (4.420)$$

Together with (4.419), this implies

$$I = \frac{5}{7} s, \quad J = \frac{2}{7} s. \quad (4.421)$$

Thus we obtain for the various energies:

$$\begin{aligned} E_{\text{kin}}^{(-)} &= \frac{3}{5} \frac{Z^2 e^2}{a_{\text{TF}}} \frac{5}{7} s, & E_{\text{pot}}^{(-)} &= -\frac{Z^2 e^2}{a_{\text{TF}}} \frac{5}{7} s, & E_{\text{e}}^{(-)} &= -\frac{2}{5} \frac{Z^2 e^2}{a_{\text{TF}}} \frac{5}{7} s, \\ E_{\text{C}}^{(-)} &= -\frac{Z^2 e^2}{a_{\text{TF}}} s, & E_{\text{ee}}^{(-)} &= \frac{Z^2 e^2}{a_{\text{TF}}} \frac{1}{7} s, \end{aligned} \quad (4.422)$$

and the total energy is

$$E_{\text{tot}}^{(-)} = \frac{2}{5} E_{\text{pot}}^{(-)} - E_{\text{ee}}^{(-)} = -\frac{1}{10} E_{\text{pot}}^{(-)} + \frac{1}{2} E_{\text{C}}^{(-)} = -\frac{3}{7} \frac{Z^2 e^2}{a_{\text{TF}}} s \approx -0.7687 Z^{7/3} \frac{e^2}{a_H}. \quad (4.423)$$

The energy increases with the nuclear charge Z like $Z^2/a_{\text{TF}} \propto Z^{7/3}$.

At the extremum, we may express the energy functional $\varepsilon[f]$ with the help of (4.420) as

$$\bar{\varepsilon}[f] = -\frac{1}{10} \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{5/2}(\xi) - \frac{1}{2} f(0) f'(0), \quad (4.424)$$

or in a form corresponding to (4.407):

$$\bar{\varepsilon}[f] \equiv -\frac{1}{10} I[f] + \frac{1}{2} J_{\text{C}}[f] = -\frac{1}{10} \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{5/2}(\xi) + \frac{1}{2} \int_0^\infty d\xi \frac{1}{\sqrt{\xi}} f^{3/2}(\xi). \quad (4.425)$$

Using the Thomas-Fermi equation (4.384), the second integral corresponding to the Coulomb energy can be reduced to a surface term yielding $J_{\text{C}}[f] = s$, so that (4.425) gives the same total energy as (4.414).

4.10.5 Virial Theorem

Note that the total energy is equal in magnitude and opposite in sign to the kinetic energy. This is a general consequence of the so-called *virial theorem* for Coulomb systems. The kinetic energy of the many-electron Schrödinger equation contains the Laplace differential operator proportional to ∇^2 , whereas the Coulomb potentials are proportional to $1/r$. For this reason, a rescaling $x \rightarrow \lambda x$ changes the sum of kinetic and total potential energies

$$E_{\text{tot}} = E_{\text{kin}} + E_{\text{pot}} \quad (4.426)$$

into

$$\lambda^2 E_{\text{kin}} + \lambda E_{\text{pot}}. \quad (4.427)$$

Since this must be extremal at $\lambda = 1$, one has the relation

$$2E_{\text{kin}} + E_{\text{pot}} = 0, \quad (4.428)$$

which proves the virial theorem

$$E_{\text{tot}} = -E_{\text{kin}}. \quad (4.429)$$

In the Thomas-Fermi model, the role of total potential energy is played by the combination $E_{\text{pot}}^{(-)} - E_{\text{ee}}^{(-)}$, and Eq. (4.422) shows that the theorem is satisfied.

4.10.6 Exchange Energy

In many-body theory it is shown that due to the Fermi statistics of the electronic wave functions, there exists an additional electron-electron *exchange interaction* which we shall now take into account. For this purpose we introduce the bilocal density of all states of negative energy by analogy with (4.363):

$$\rho_{\text{cl}}^{(-)}(\mathbf{x}_b, \mathbf{x}_a) = \int_{V(\bar{\mathbf{x}})}^0 dE \rho_{\text{cl}}^{(-)}(E; \mathbf{x}_b, \mathbf{x}_a). \quad (4.430)$$

In three dimensions we insert (4.280) and rewrite the energy integral as

$$\int_{V(\bar{\mathbf{x}})}^0 dE = \frac{1}{M} \int_0^{p_F(\bar{\mathbf{x}})} dp p, \quad (4.431)$$

with the Fermi momentum $p_F(\bar{\mathbf{x}})$ of the neutral atom at the point $\bar{\mathbf{x}}$ [see (4.365)]. In this way we find

$$\rho_{\text{cl}}^{(-)}(\mathbf{x}_b, \mathbf{x}_a) = \frac{p_F^3(\bar{\mathbf{x}})}{2\pi^2 \hbar^3} \frac{1}{z^3} (\sin z - z \cos z), \quad (4.432)$$

where

$$z \equiv p_F(\bar{\mathbf{x}})R/\hbar. \quad (4.433)$$

This expression can, incidentally, be obtained alternatively by analogy with the local expression (4.366) from a momentum integral over free wavefunctions

$$\rho_{\text{cl}}^{(-)}(\mathbf{x}_b, \mathbf{x}_a) = \int_{|\mathbf{p}| \leq p_F(\bar{\mathbf{x}})} \frac{d^3 p}{(2\pi\hbar)^D} e^{i\mathbf{p}(\mathbf{x}_b - \mathbf{x}_a)/\hbar}. \quad (4.434)$$

The simplest way to derive the exchange energy is to re-express the density of states $\rho^{(-)}(E; \mathbf{x})$ as the diagonal elements of the bilocal density

$$\rho^{(-)}(\mathbf{x}) = \rho^{(-)}(\mathbf{x}_b, \mathbf{x}_a) \quad (4.435)$$

and rewrite the electron-electron energy (4.396) as

$$E_{\text{ee}}^{(-)} = 4 \times \frac{e^2}{2} \int d^3 x d^3 x' \rho^{(-)}(\mathbf{x}, \mathbf{x}) \frac{1}{4\pi|\mathbf{x} - \mathbf{x}'|} \rho^{(-)}(\mathbf{x}', \mathbf{x}'). \quad (4.436)$$

The factor 4 accounts for the four different spin pairs in the first and the second bilocal density.

$$\uparrow \uparrow; \uparrow \uparrow; \uparrow \uparrow; \uparrow \downarrow; \downarrow \downarrow; \downarrow \downarrow; \downarrow \uparrow; \uparrow \uparrow; \downarrow \downarrow; \downarrow \downarrow; \downarrow \downarrow.$$

In the first and last case, there exists an exchange interaction which is obtained by interchanging the second arguments of the bilocal densities and changing the sign. This yields

$$E_{\text{exch}}^{(-)} = -2 \times \frac{e^2}{2} \int d^3 x d^3 x' \rho^{(-)}(\mathbf{x}, \mathbf{x}') \frac{1}{4\pi|\mathbf{x} - \mathbf{x}'|} \rho^{(-)}(\mathbf{x}', \mathbf{x}). \quad (4.437)$$

The integral over $\mathbf{x} - \mathbf{x}'$ may be performed using the formula

$$\int_0^\infty dz z^2 \frac{1}{z} \left[\frac{1}{z^3} (\sin z - z \cos z) \right]^2 = \frac{1}{4}, \quad (4.438)$$

and we obtain the exchange energy

$$E_{\text{exch}}^{(-)} = -\frac{e^2}{4\pi^3} \int d^3\bar{\mathbf{x}} \left[\frac{p_F(\bar{\mathbf{x}})}{\hbar} \right]^4. \quad (4.439)$$

Inserting

$$p_F(\mathbf{x}) = \sqrt{\frac{2Z}{a_H a_{\text{TF}}} \frac{f(\xi)}{\xi}}, \quad (4.440)$$

the exchange energy becomes

$$E_{\text{exch}}^{(-)} = -\frac{4}{\pi^2} \frac{a_{\text{TF}}}{a_H} I_2 \frac{Z^2}{a_H} \approx -0.3588 Z^{5/3} \frac{e^2}{a_H} I_2, \quad (4.441)$$

where I_2 is the integral

$$I_2 \equiv \int_0^\infty d\xi f^2(\xi) \approx 0.6154. \quad (4.442)$$

Hence we obtain

$$E_{\text{exch}}^{(-)} \approx -0.2208 Z^{5/3} \frac{e^2}{a_H}, \quad (4.443)$$

giving rise to a correction factor

$$C_{\text{exch}}(Z) = 1 + 0.2872 Z^{-2/3} \quad (4.444)$$

to the Thomas-Fermi energy (4.423).

4.10.7 Quantum Correction Near Origin

The Thomas-Fermi energy with exchange corrections calculated so far would be reliable for large- Z only if the potential was smooth so that the semiclassical approximation is applicable. Near the origin, however, the Coulomb potential is singular and this condition is no longer satisfied. Some more calculational effort is necessary to account for the quantum effects near the singularity, based on the following observation [6]. For levels with an energy smaller than some value $\varepsilon < 0$, which is large compared to the ground state energy $Z^2 e^2 / a_H$, but much smaller than the average Thomas Fermi energy per particle $Z^2 e^2 / aZ \sim Z^2 e^2 / a_H Z^{2/3}$, i.e., for

$$\frac{Z^2 e^2}{a_H} \frac{1}{Z^{2/3}} \ll -\varepsilon \ll \frac{Z^2 e^2}{a_H}, \quad (4.445)$$

we have to recalculate the energy. Let us define a parameter ν by

$$-\varepsilon \equiv \frac{Z^2}{2a_H \nu^2}, \quad (4.446)$$

which satisfies

$$1 \ll \nu^2 \ll Z^{2/3}. \quad (4.447)$$

The contribution of the levels with energy

$$\frac{p^2}{2M} - \frac{Ze^2}{r} < -\varepsilon \quad (4.448)$$

to $E_{\text{kin,TF}}^{(-)}$ is given by an integral like (4.371), where the momentum runs from 0 to $p_{-\varepsilon}(\mathbf{x}) = \sqrt{2M[-\varepsilon - V(\mathbf{x})]}$. In the kinetic energy (4.372), the potential $V(\mathbf{x})$ is simply replaced by $-\varepsilon - V(\mathbf{x})$, and the spatial integral covers the small sphere of radius r_{max} , where $-\varepsilon - V(\mathbf{x}) > 0$. For the screening function $f(\xi) = V(r)r/Ze^2$ this implies the replacement

$$f(\xi) \rightarrow [-\varepsilon - V(r)] \frac{r}{Ze^2} = f(\xi) - \xi/\xi_m, \quad (4.449)$$

where

$$\xi_m = \frac{2\nu^2 a_H}{Z a} \quad (4.450)$$

is small of the order $Z^{-2/3}$. Using relation (4.429) between total and kinetic energies we find the additional total energy

$$\Delta E_{\text{tot}}^{(-)} = -\frac{3}{5} \frac{Z^2 e^2}{a} \int_0^{\xi_{\text{max}}} d\xi \frac{1}{\sqrt{\xi}} [f(\xi) - \xi/\xi_m]^{5/2}, \quad (4.451)$$

where $\xi_{\text{max}} \equiv r_{\text{max}}/a$ is the place at which the integrand vanishes, i.e., where

$$\xi_{\text{max}} = Ze^2 \varepsilon f(\xi_{\text{max}})/a, \quad (4.452)$$

this being the dimensionless version of

$$-\varepsilon - V(r_{\text{max}}) = 0. \quad (4.453)$$

Under the condition (4.447), the slope of $f(\xi)$ may be ignored and we can use the approximation

$$\xi_{\text{max}} \approx \xi_m \quad (4.454)$$

corresponding to $r_{\text{max}} = Ze^2/\varepsilon$, with an error of relative order $Z^{-2/3}$. After this, the integral

$$\int_0^{1/c} d\lambda \frac{1}{\sqrt{\lambda}} (1 - c\lambda)^{5/2} = \frac{1}{\sqrt{c}} B(1/2, 7/2) = \frac{1}{\sqrt{c}} \frac{5}{8} \pi, \quad (4.455)$$

yielding a Beta function $B(x, y) \equiv \Gamma(x)\Gamma(y)/\Gamma(x+y)$, leads to an energy

$$\Delta E_{\text{tot}}^{(-)} = -\frac{3}{5} \frac{Z^2 e^2}{a} \frac{5}{8} \frac{\pi}{M} \sqrt{\frac{a_H}{2a}} \frac{\nu}{Z^{1/3}}, \quad (4.456)$$

showing that the correction to the energy will be of relative order $1/Z^{1/3}$. Expressing a in terms of a_H via (4.380), we find

$$\Delta E_{\text{tot}}^{(-)} = -\frac{Z^2 e^2}{a_H} \nu. \quad (4.457)$$

The point is now that this energy can easily be calculated more precisely. Since the slope of the screening function can be ignored in the small selected radius, the potential is Coulomb-like and we may simply sum all occupied exact quantum-mechanical energies E_n in a Coulomb potential $-Ze^2/r$ which lie below the total energy $-\varepsilon$. They depend on the principal quantum number n in the well-known way:

$$E_n = -\frac{Z^2 e^2}{a_H} \frac{1}{2n^2}. \quad (4.458)$$

Each level occurs with angular momentum $l = 0, \dots, n-1$, and with two spin directions so that the total degeneracy is $2n^2$. By Eq. (4.446), the maximal energy $-\varepsilon$ corresponds to a maximal quantum number $n_{\text{max}} = \nu$. The sum of all energies E_n up to the energy ε is therefore given by

$$\begin{aligned} \Delta_{\text{QM}} E_{\text{tot}}^{(-)} &= -2 \frac{Z^2 e^2}{a_H} \frac{1}{2} \sum_{n=0}^{\nu} 1 \\ &= -\frac{Z^2 e^2}{a_H} [\nu], \end{aligned} \quad (4.459)$$

where $[\nu]$ is the largest integer number smaller than ν . The difference between the semiclassical energy (4.456) and the true quantum-mechanical one (4.459) yields the desired quantum correction

$$\Delta E_{\text{corr}}^{(-)} = -\frac{Z^2 e^2}{a_H} ([\nu] - \nu). \quad (4.460)$$

For large ν , we must average over the step function $[\nu]$, and find

$$\langle [\nu] \rangle = \nu - \frac{1}{2}, \quad (4.461)$$

and therefore

$$\Delta E_{\text{corr}}^{(-)} = \frac{Z^2 e^2}{a_H} \frac{1}{2}. \quad (4.462)$$

This is the correction to the energy of the atom due to the failure of the quasi-classical expansion near the singularity of the Coulomb potential. With respect to the Thomas-Fermi energy (4.423) which grows with increasing nuclear charge Z like $-0.7687 Z^{7/3} e^2/a_H$, this produces a correction factor

$$C_{\text{sing}}(Z) = 1 - \frac{7a_{\text{TF}}}{6a_H s} \approx 1 - 0.6504 Z^{-1/3} \quad (4.463)$$

to the Thomas-Fermi energy (4.423).

4.10.8 Systematic Quantum Corrections to Thomas-Fermi Energies

Just as for the density of states in Section 4.9, we can derive the quantum corrections to the energies in the Thomas-Fermi atom. The electrons fill up all negative-energy levels in the combined potential $V(\mathbf{x})$. The density of states in these levels can be selected by a Heaviside function of the negative Hamiltonian operator as follows:

$$\rho^{(-)}(\mathbf{x}) = \langle \mathbf{x} | \Theta(-\hat{H}) | \mathbf{x} \rangle. \quad (4.464)$$

Using the Fourier representation (1.312) for the Heaviside function we write

$$\Theta(-\hat{H}) = \int_{-\infty}^{\infty} \frac{dt}{2\pi i(t - i\eta)} e^{-i\hat{H}t/\hbar}, \quad (4.465)$$

and obtain the integral representation

$$\rho^{(-)}(\mathbf{x}) = \int_{-\infty}^{\infty} \frac{dt}{2\pi i(t - i\eta)} (\mathbf{x} t | \mathbf{x} 0). \quad (4.466)$$

Inserting the short-time expansion (4.258), and the correspondence $t \rightarrow i\hbar d/dV$ in the time integral, we find

$$\rho(\mathbf{x}) = \left\{ 1 - \frac{\hbar^2}{12M} \nabla^2 V(\mathbf{x}) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} \rho_{\text{TF}}(\mathbf{x}). \quad (4.467)$$

The potential energy is simply given by

$$E_{\text{pot}}^{(-)}(\mathbf{x}) = \langle \mathbf{x} | V(\mathbf{x}) \Theta(-\hat{H}) | \mathbf{x} \rangle = \int d^3x V(\mathbf{x}) \rho^{(-)}(\mathbf{x}). \quad (4.468)$$

With (4.467), this becomes

$$E_{\text{pot}}^{(-)}(\mathbf{x}) = V(\mathbf{x}) \left\{ 1 - \frac{\hbar^2}{12M} \nabla^2 V(\mathbf{x}) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} \rho_{\text{TF}}(\mathbf{x}). \quad (4.469)$$

For the energy of all negative-energy states we may introduce a density function

$$E^{(-)}(\mathbf{x}) = \langle \mathbf{x} | \hat{H} \Theta(-\hat{H}) | \mathbf{x} \rangle. \quad (4.470)$$

The derivative of this with respect to $V(\mathbf{x})$ is equal to the density of states (4.464):

$$\frac{\partial}{\partial V(\mathbf{x})} E^{(-)}(\mathbf{x}) = \rho^{(-)}(\mathbf{x}). \quad (4.471)$$

This follows right-away from $\partial \hat{H} / \partial V(\mathbf{x}) = 1$ and $\partial [x \Theta(x)] / \partial x = \Theta(x)$.

Inserting the representation (4.465), the factor \hat{H} can be obtained by applying the differential operator $i\hbar \partial_t$ to the exponential function. After a partial integration, we arrive at the integral representation

$$E^{(-)}(\mathbf{x}) = i\hbar \int_{-\infty}^{\infty} \frac{dt}{2\pi i(t - i\eta)^2} (\mathbf{x} t | \mathbf{x} 0). \quad (4.472)$$

Inserting on the right-hand side the expansion (4.258), the leading term produces the local *Thomas-Fermi energy density* (4.372):

$$E_{\text{TF}}^{(-)}(\mathbf{x}) = - \left(\frac{M}{2\pi\hbar} \right)^{D/2} \frac{1}{\Gamma(D/2 + 2)} [-V(\mathbf{x})]^{D/2+1}. \quad (4.473)$$

The short-time expansion terms yield, with the correspondence $t \rightarrow i\hbar d/dV$, the energy including the quantum corrections

$$E^{(-)}(\mathbf{x}) = \left\{ 1 - \frac{\hbar^2}{12M} \nabla^2 V(\mathbf{x}) \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} [\nabla V(\mathbf{x})]^2 \frac{d^3}{dV^3} + \dots \right\} E_{\text{TF}}^{(-)}(\mathbf{x}). \quad (4.474)$$

One may also calculate selectively the kinetic energy density from the expression

$$E^{(-)}(\mathbf{x}) = \frac{1}{2M} \langle \mathbf{x} | \hat{\mathbf{p}}^2 \Theta(-\hat{H}) | \mathbf{x} \rangle. \quad (4.475)$$

This can obviously be extracted from (4.472) by a differentiation with respect to the mass:

$$\begin{aligned} E_{\text{kin}}^{(-)}(\mathbf{x}) &= -M \frac{\partial}{\partial M} i\hbar \int_{-\infty}^{\infty} \frac{dt}{2\pi i(t-i\eta)^2} \langle \mathbf{x} | e^{-i\hat{H}t/\hbar} | \mathbf{x} \rangle \\ &= -M \frac{\partial}{\partial M} E^{(-)}(\mathbf{x}). \end{aligned} \quad (4.476)$$

According to Eq. (4.474), the first quantum correction to the energy $E_e^{(-)}$ is

$$\begin{aligned} \Delta E_e^{(-)} &= - \int d^3x \left[-\frac{\hbar^2}{12M} \nabla^2 V \frac{d^2}{dV^2} - \frac{\hbar^2}{24M} (\nabla V)^2 \frac{d^3}{dV^3} \right] \\ &\quad \times 2 \frac{2}{5} \left(\frac{M}{2\pi\hbar} \right)^{3/2} \frac{1}{\Gamma(5/2)} (-V)^{5/2} \\ &= \frac{\sqrt{2M}}{12\hbar\pi^2} \int d^3x \left[(-V)^{1/2} \nabla^2 V - \frac{1}{4} (-V)^{-3/2} (\nabla V)^2 \right]. \end{aligned} \quad (4.477)$$

It is useful to bring the second term to a more convenient form. For this we note that by the chain rule of differentiation

$$\nabla^2 V^{3/2} = \frac{3}{2} \nabla [V^{1/2} \nabla V] = \frac{3}{4} [V^{-1/2} (\nabla V)^2 + 2V^{1/2} \nabla^2 V]. \quad (4.478)$$

As a consequence we find

$$\Delta E_e^{(-)} = \frac{\sqrt{2M}}{24\hbar\pi^2} \int d^3x \left[(-V)^{1/2} \nabla^2 V - \frac{2}{3} \nabla^2 (-V)^{3/2} \right]. \quad (4.479)$$

This energy evaluated with the potential V determined above describes directly the lowest correction to the total energy. To prove this, consider the new total energy [recall (4.398)]

$$E_{\text{tot}}^{(-)} = E_e^{(-)} + \Delta E_e^{(-)} - \mathcal{E}_{\varphi\varphi}[\varphi]. \quad (4.480)$$

Extremizing this in the field $\varphi(\mathbf{x})$ and denoting the new extremal field by $\varphi(\mathbf{x}) + \Delta\varphi(\mathbf{x})$, we obtain for $\Delta\varphi(\mathbf{x})$ the field equation:

$$\frac{\delta}{\delta V(\mathbf{x})} [E_e^{(-)} + \Delta E_e^{(-)}] + \frac{1}{e^2} \nabla^2 [\varphi(\mathbf{x}) + \Delta\varphi(\mathbf{x})] = 0. \quad (4.481)$$

Taking advantage of the initial extremality condition (4.399), we derive the field equation

$$\frac{1}{e^2} \nabla^2 \Delta\varphi(\mathbf{x}) = -\frac{\delta \Delta E_e^{(-)}}{\delta V(\mathbf{x})}. \quad (4.482)$$

If we now expand the corrected energy up to first order in $\Delta E_e^{(-)}$ and $\Delta\varphi(\mathbf{x})$, we obtain

$$E_{\text{tot}}^{(-)} = E_e^{(-)} + \Delta E_e^{(-)} + \int d^3x \frac{\delta E_e^{(-)}}{\delta V(\mathbf{x})} \Delta\varphi(\mathbf{x}) - \mathcal{E}_{\varphi\varphi}[\varphi] - \frac{1}{4\pi e^2} \int d^3x \nabla\varphi(\mathbf{x}) \nabla\Delta\varphi(\mathbf{x}). \quad (4.483)$$

Due to the extremality property (4.399) of the uncorrected energy at the original field $\varphi(\mathbf{x})$, the second and fourth terms cancel each other, and the correction to the total energy is indeed given by (4.479).

Actually, the statement that the energy (4.479) is the next quantum correction is not quite true. When calculating the first quantum correction in Subsection 4.10.7, we subtracted the contribution of all orbits with total energies

$$E < -\varepsilon. \quad (4.484)$$

After that we calculated in (4.459) the *exact* quantum corrections coming from the neighborhood

$$r < r_{\max} = Ze^2\varepsilon \quad (4.485)$$

of the origin. Thus we have to omit this neighborhood from all successive terms in the semiclassical expansion, in particular from (4.479). According to the remarks after Eq. (4.372), the energy $E_e^{(-)}$ of electrons filling all levels up to a total energy E_F is found from (4.368) by replacing $(-V)^{D/2+1}$ by $(1 - E_F\partial/E_F)(E_F - V)^{D/2+1}$. The energy level satisfying (4.484) correspond to a Fermi level E_F , so that the energy of the electrons in these levels is

$$E_e^{(-)} = 2 \frac{2}{5} E_{\text{pot TF}}^{(-)} = -2 \frac{2}{5} \left(\frac{M}{2\pi\hbar} \right)^{3/2} \frac{1}{\Gamma(5/2)} (1 - E_F\partial_{E_F}) \int d^3x [-E_F - V(\mathbf{x})]^{5/2}. \quad (4.486)$$

We therefore have to subtract from the correction (4.477) a term

$$\Delta_{\text{sub}} E_e^{(-)} = (1 - E_F\partial_{E_F}) \frac{\sqrt{2M}}{12\hbar\pi^2} \int d^3x \left[(-E_F - V)^{1/2} \nabla^2 V - \frac{1}{4} (-E_F - V)^{-3/2} (\nabla V)^2 \right]. \quad (4.487)$$

The true correction can then be decomposed into a contribution from the finite region outside the small sphere

$$\Delta E_{\text{outside}}^{(-)} = \frac{\sqrt{2M}}{24\hbar\pi^2} \int_{r \geq r_{\max}} d^3x (-V)^{1/2} \nabla^2 V, \quad (4.488)$$

plus a subtracted contribution from the inside

$$\Delta E_{\text{inside}}^{(-)} = \frac{\sqrt{2M}}{24\hbar\pi^2} \int_{r < r_{\max}} d^3x \left[(-V)^{1/2} - (1 - E_F\partial_{E_F})(-E_F - V)^{1/2} \right] \nabla^2 V, \quad (4.489)$$

plus a pure gradient term

$$\Delta E_{\text{grad}}^{(-)} = -\frac{\sqrt{2M}}{24\hbar\pi^2} \frac{2}{3} \left[\int d^3x \nabla^2 (-V)^{3/2} - \int_{r < r_{\max}} d^3x \nabla^2 (1 - E_F\partial_{E_F})(-E_F - V)^{3/2} \right]. \quad (4.490)$$

The last two volume integrals can be converted into surface integrals. Either integrand vanishes on its outer surface [recall (4.452)]. At the inner surface, an infinitesimal sphere around the origin, the integrands coincide so that the energy (4.490) vanishes.

The energy (4.489) does not vanish but can be ignored in the present approximation. At the δ -function at the nuclear charge in $\nabla^2 V$, the difference $(-V)^{1/2} - (1 - E_F\partial_{E_F})(-E_F - V)^{1/2}$ vanishes. In the integral, we may therefore replace $\nabla^2 V(\mathbf{x})$ by $-4\pi e^2 n(\mathbf{x})$ [dropping the δ -function in (4.374)]. In the small neighborhood of the origin, the integral is suppressed by a power of $Z^{-4/3}$ as will be seen below.

Thus, only the outside energy (4.488) needs to be evaluated, where the small sphere excludes the nuclear charge, so that we may replace $\nabla^2 V(\mathbf{x})$ as in the last integral. Thus we obtain

$$\Delta E_{\text{outside}}^{(-)} = -\frac{2e^2 M^2 M}{9\pi^3 \hbar^4} \int_{r < r_{\max}} d^3x [-V(\mathbf{x})]^2. \quad (4.491)$$

Expressing V in terms of the screening function and going to reduced variables, the quantum correction takes the final form

$$\begin{aligned}\Delta E_{\text{outside}}^{(-)} &= -\frac{8}{9\pi^2} \frac{a}{a_H} \left[\int d\xi f^2(\xi) \right] Z^{5/3} \\ &\approx -0.07971 \frac{e^2}{a_H} I_2 Z^{5/3} \approx -0.04905 Z^{5/3} \frac{e^2}{a_H},\end{aligned}\quad (4.492)$$

where I_2 is the integral over $f^2(\xi)$ calculated in Eq. (4.442). We have re-extended the integration over the entire space with a relative error of order $Z^{-2/3}$, due to the smallness of the sphere. The correction factor to the leading Thomas-Fermi energy caused by this is

$$C_{\text{QM}} = 1 + 0.06381 Z^{-2/3}. \quad (4.493)$$

In the reduced variables, the order of magnitude of the ignored energy (4.489) can most easily be estimated. It reads

$$\Delta E_{\text{inside}}^{(-)} = -\frac{8}{9\pi^2} \frac{a}{a_H} \int_0^{\xi_{\text{max}}} d\xi \left[f^2(\xi) - \sqrt{f(\xi) - \xi/\xi_m} f^{3/2}(\xi) \right] Z^{5/3}. \quad (4.494)$$

Since ξ_{max} and ξ_m are of the order $Z^{-2/3}$, this energy is of the relative order $Z^{-4/3}$ and thus negligible since we want to find here only corrections up to $Z^{-2/3}$.

Observe that the quantum correction (4.495) is of relative order $Z^{-2/3}$ and precisely a fraction $2/9$ of the exchange energy (4.441). Both energies together are therefore

$$\Delta E_{\text{inside}}^{(-)} + E_{\text{exch}}^{(-)} = \frac{11}{9} E_{\text{exch}}^{(-)} \approx -0.2699 Z^{5/3} \frac{e^2}{a_H}. \quad (4.495)$$

The corrections of order $Z^{-2/3}$ can be collected in the expression

$$\Delta E_{\text{inside}}^{(-)} + E_{\text{exch}}^{(-)} = -0.7687 Z^{7/3} \frac{e^2}{a_H} \times C_2(Z), \quad (4.496)$$

where $C_2(Z)$ is the correction factor

$$C_2(Z) = 1 + 0.3510 Z^{-2/3} + \dots \quad (4.497)$$

Including also the $Z^{-1/3}$ -correction (4.463) from the origin we obtain the total energy

$$E_{\text{tot}}^{(-)} = -0.7687 Z^{7/3} \frac{e^2}{a_H} \times C_{\text{tot}}(Z), \quad (4.498)$$

with the total correction factor

$$C_{\text{tot}}(Z) = 1 - 0.6504 Z^{-1/3} + 0.3510 Z^{-2/3} + \dots \quad (4.499)$$

This large- Z approximation is surprisingly accurate. The experimental binding energy of mercury with $Z = 80$ is

$$E_{\text{Hg}}^{\text{exp}} \approx -18130, \quad (4.500)$$

in units of $e^2/a_H = 2 \text{ Ry}$, whereas the large- Z formula (4.498) with the correction factor (4.499) yields the successive approximations including the first, second, and third term in (4.499):

$$E_{\text{Hg}} \approx -(21200, 18000, 18312) \quad \text{for} \quad C(80) = (1, 0.849, 0.868). \quad (4.501)$$

Even at the lowest value $Z = 1$, the binding energy of the hydrogen atom

$$E_{\text{H}}^{\text{exp}} \approx -\frac{1}{2} \quad (4.502)$$

is quite rapidly approached by the successive approximations

$$E_{\text{H}} \approx -(0.7687, 0.2687, 0.5386) \quad \text{for} \quad C(1) = (1, 0.350, 0.701). \quad (4.503)$$

4.11 Classical Action of Coulomb System

Consider an electron of mass M in an attractive Coulomb potential of a proton at the coordinate origin

$$V_C(\mathbf{x}) = -\frac{e^2}{r}. \quad (4.504)$$

If the proton is substituted by a heavier nucleus, e^2 has to be multiplied by the charge Z of that nucleon. The Lagrangian of this system is

$$L = \frac{M}{2}\dot{\mathbf{x}}^2 - \frac{e^2}{r}. \quad (4.505)$$

Because of rotational invariance, the orbital angular momentum is conserved and the motion is restricted to a plane, say $x - y$. If ϕ denotes the azimuthal angle in this plane, the constant orbital momentum is

$$l = Mr^2\dot{\phi}. \quad (4.506)$$

The conserved energy is

$$E = \frac{M}{2}(\dot{r}^2 + r^2\dot{\phi}^2) - \frac{e^2}{r}. \quad (4.507)$$

Together with (4.506) we find

$$\dot{r} = \frac{1}{M}p_E(r); \quad p_E(r) = \sqrt{2M[E - V_{\text{eff}}(r)]}, \quad (4.508)$$

where $V_{\text{eff}}(r) = V_C(r) + V_l(r)$ is the sum of the Coulomb potential and the *angular barrier* potential

$$V_l(r) = \frac{l^2}{2Mr^2}. \quad (4.509)$$

The differential equation (4.508) is solved by the integral relation

$$t = \int dr \frac{M}{p_E(r)}. \quad (4.510)$$

For the angle ϕ , Eq. (4.506) implies

$$\frac{d\phi}{dr} = \frac{l}{r^2 p_E(r)}, \quad (4.511)$$

which is solved by the integral

$$\phi = l \int dr \frac{1}{r^2 p_E(r)}. \quad (4.512)$$

Inserting $p_E(r)$ from (4.508) this becomes explicitly

$$\phi = l \int \frac{dr}{r} \left[2ME \left(r^2 + \frac{e^2 r}{E} - \frac{l^2}{2ME} \right) \right]^{-1/2}, \quad (4.513)$$

while (4.510) reads

$$t = M \int dr r \left[2ME \left(r^2 + \frac{e^2 r}{E} - \frac{l^2}{2ME} \right) \right]^{-1/2}. \quad (4.514)$$

Consider now the motion for negative energies. Defining

$$\bar{p}_E \equiv p_{-E}(\infty) = \sqrt{-2ME}, \quad (4.515)$$

and introducing the parameters

$$a \equiv \frac{e^2}{2|E|} = \frac{Me^2}{\bar{p}_E^2}, \quad \epsilon^2 \equiv 1 - \frac{l^2 \bar{p}_E^2}{M^2 e^4} = 1 - \frac{l^2}{aMe^2} = 1 - \frac{l^2 v_a^2}{e^4}, \quad v_a = \sqrt{\frac{e^2}{aM}} = \frac{\bar{p}_E}{M}, \quad (4.516)$$

we obtain

$$\phi = \frac{l}{Mv_a} \int \frac{dr}{r} \frac{1}{\sqrt{a^2 \epsilon^2 - (r-a)^2}}, \quad (4.517)$$

$$t = \frac{1}{v_a} \int dr \frac{r}{\sqrt{a^2 \epsilon^2 - (r-a)^2}}, \quad (4.518)$$

where v_a is the velocity associated with the momentum \bar{p}_E . The ratio

$$\omega = \frac{v_a}{a} \quad (4.519)$$

is the inverse period of the orbit, also called mean motion, which satisfies $\omega^2 a^3 = e^2/M$, the third *Kepler law*. In the limit $E \rightarrow 0$, the major semiaxis a becomes infinite, and so does ω . The eccentricity vanishes and the orbit is parabolic.

Introducing the variable

$$h \equiv a(1 - \epsilon^2) = \frac{l^2}{Me^2} = \frac{l^2}{\bar{p}_E^2 a}, \quad (4.520)$$

and observing that

$$\frac{l}{Mv_a} = a\sqrt{1 - \epsilon^2}, \quad (4.521)$$

the first equation is solved by

$$\frac{h}{r} = 1 + \epsilon \cos(\phi - \phi_0). \quad (4.522)$$

This follows immediately from the fact that

$$\sin(\phi - \phi_0) = \frac{\sqrt{1 - \epsilon^2}}{\epsilon r} \sqrt{a^2 \epsilon^2 - (r-a)^2}. \quad (4.523)$$

The relation (4.522) describes an ellipse with principal axes $a = h/(1 - \epsilon^2)$, $b = h/\sqrt{1 - \epsilon^2}$, and an eccentricity ϵ (see Fig. 4.3). In the orbital plane, the Cartesian

Figure 4.3 Orbits in Coulomb potential showing the parameter h and the eccentricity ϵ of ellipse ($E < 0$) and hyperbola ($E > 0$) in attractive and repulsive cases.

coordinates of the motion are

$$x = h \frac{\cos(\phi - \phi_0)}{1 + \epsilon \sin(\phi - \phi_0)}, \quad y = h \frac{\sin(\phi - \phi_0)}{1 + \epsilon \sin(\phi - \phi_0)}. \quad (4.524)$$

For positive energy, we define a momentum

$$p_E = p_E(\infty) = \sqrt{2ME}, \quad (4.525)$$

and the parameters

$$a \equiv \frac{e^2}{2|E|} = \frac{Me^2}{p_E^2}, \quad \epsilon^2 \equiv 1 + \frac{l^2 p_E^2}{M^2 e^4} = 1 + \frac{l^2}{a M e^2} = 1 + \frac{l^2 v_a^2}{e^4}, \quad v_a = \sqrt{\frac{e^2}{aM}} = \frac{p_E}{M}. \quad (4.526)$$

The eccentricity ϵ is now larger than unity. Apart from this, the solutions to the equations of motion are the same as before, and the orbits are hyperbolas as shown in Fig. 4.3. The y -coordinate above the focus is now

$$h = a(\epsilon^2 - 1) = \frac{l^2}{M e^2} = \frac{l^2}{p_E^2 a}. \quad (4.527)$$

For a repulsive interaction, we change the sign of e^2 in the above equations. The equation (4.522) for r becomes now

$$\frac{h}{r} = -1 + \epsilon \cos(\phi - \phi_0), \quad (4.528)$$

and yields the right-hand hyperbola shown in Fig. 4.3.

For later discussions in Chapter 13, where we shall solve the path integral of the Coulomb system exactly, we also note that by introducing a new variable in terms of the variable ξ , to so-called *eccentric anomaly*

$$r = a(1 - \epsilon \cos \xi), \quad (4.529)$$

we can immediately perform the integral (4.518) to find

$$t = \frac{a}{v_a} \int d\xi (1 - \epsilon \cos \xi) = \frac{1}{\omega} (\xi - \epsilon \sin \xi), \quad (4.530)$$

where we have chosen the integration constant to zero. Using Eq. (4.528) we see that

$$x = r \cos \phi = \frac{h - r}{\epsilon} = a(\cos \xi - \epsilon), \quad (4.531)$$

$$y = r \sin \phi = \sqrt{r^2 - x^2} = a\sqrt{1 - \epsilon^2} \sin \xi = b \sin \xi. \quad (4.532)$$

Equations (4.529) and (4.530) represent a parametric representation of the orbit. From Eqs. (4.530) and (4.529) we see that

$$\frac{dt}{r} = \frac{1}{a} d(\xi/\omega), \quad (4.533)$$

exhibiting ξ/ω is a path-dependent *pseudotime*. As a function of this pseudotime, the coordinates x and y oscillate harmonically.

The pseudotime facilitates the calculation of the classical action $A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)$, as done first in the eighteenth century by Lambert.¹⁵ If we denote the derivative with respect to ξ by a prime, the classical action reads

$$A = \int_{\xi_a}^{\xi_b} d\xi \left[\frac{M}{2r} a\omega (x'^2 + y'^2) + \frac{e^2}{a\omega} \right]. \quad (4.534)$$

For an elliptic orbit with principal axes a, b , this becomes

$$A = \int_{\xi_a}^{\xi_b} d\xi \left[\frac{M}{2} \omega \frac{a^2 \sin^2 \xi + b^2 \cos^2 \xi}{1 - \epsilon \cos \xi} \right] + M\omega a^2 (\xi_b - \xi_a). \quad (4.535)$$

After performing the integral using the formula

$$\int \frac{d\xi}{1 - \epsilon \cos \xi} = \frac{2}{1 - \epsilon^2} \arctan \frac{\sqrt{1 - \epsilon^2} \tan(\xi/2)}{1 - \epsilon}, \quad (4.536)$$

we find

$$A = \frac{M}{2} a^2 \omega [3(\xi_b - \xi_a) + \epsilon(\sin \xi_b - \sin \xi_a)]. \quad (4.537)$$

Introducing the parameters α, β, γ , and δ by the relations

$$\cos \alpha \equiv \epsilon \cos[(\xi_b + \xi_a)/2], \quad \beta \equiv (\xi_b - \xi_a)/2, \quad \gamma \equiv \alpha + \beta, \quad \delta \equiv \alpha - \beta, \quad (4.538)$$

¹⁵ Johann Heinrich Lambert (1728–1777) was an ingenious autodidactic taylor's son who with 16 years found *Lambert's law* for the apparent motion of comets (and planets) on the sky: If the sun lies on the concave (convex) side of the apparent orbit, comet is closer to (farther from) the sun than the earth. In addition, he laid the foundations to photometry.

the action becomes

$$A = \frac{M}{2} a^2 \omega [(3\gamma + \sin \gamma) - (3\delta + \sin \delta)]. \quad (4.539)$$

Using (4.530), we find for the elapsed time $t_b - t_a$ the relation

$$t_b - t_a = \frac{1}{\omega} [(\gamma - \sin \gamma) \mp (\delta - \sin \delta)]. \quad (4.540)$$

The \mp -signs apply to an ellipse whose short or long arc connects the two endpoints, respectively. The parameters γ and δ in the action and in the elapsed time are related to the endpoints \mathbf{x}_b and \mathbf{x}_a by

$$r_b + r_a + R = 4a \sin^2(\gamma/2) \equiv 4a\rho_+, \quad r_b + r_a - R = 4a \sin^2(\delta/2) \equiv 4a\rho_-, \quad (4.541)$$

where $r_b \equiv |\mathbf{x}_b|$, $r_a \equiv |\mathbf{x}_a|$, $R \equiv |\mathbf{x}_b - \mathbf{x}_a|$, and $\rho_{\pm} \in [0, 1]$. Expressing the semimajor axis in (4.539) in terms of ω as $a = (e^2/M\omega^2)^{1/3}$, and ω in terms of $t_b - t_a$ we obtain the desired classical action $A(\mathbf{x}_b, \mathbf{x}_a; t_b - t_a)$.

The elapsed time depends on the endpoints via a transcendental equation which can only be solved by a convergent power series (Lambert's series)

$$t_b - t_a = \frac{1}{\sqrt{2}\omega} \sum_{j=1}^{\infty} \frac{(2j)!}{2^{2j} j!^2} \frac{1}{j^2 - 1/4} e^{j-1} (\rho_+^{j+1/2} \pm \rho_-^{j+1/2}). \quad (4.542)$$

In the limit of a parabolic orbit the series has only the first term, yielding

$$t_b - t_a = \frac{\sqrt{2}}{3\omega} (\rho_+^{3/2} \pm \rho_-^{3/2}). \quad (4.543)$$

We can also express a and ω in terms of the energy E as $e^2/(-2E)$ and $\sqrt{-2E/Ma^2}$, respectively, and go over to the eikonal $S(\mathbf{x}_b, \mathbf{x}_a; E)$ via the Legendre transformation (4.87). Substituting for $t_b - t_a$ the relation (4.540), we obtain for the short arc of the ellipse

$$S(\mathbf{x}_b, \mathbf{x}_a; E) = A(\mathbf{x}_b, \mathbf{x}_a; E) + (t_b - t_a) E = \frac{M}{2} a^2 \omega 4(\gamma - \delta). \quad (4.544)$$

For a complete orbit, the expression (4.537) yields a total action

$$A = \frac{M}{2} a^2 \omega 2\pi(1+2) = \frac{M}{2} v_a^2 \frac{2\pi}{\omega} (1+2) = \frac{\bar{p}_E}{2M} \frac{2\pi}{\omega} (1+2), \quad (4.545)$$

where the numbers 1 and 2 indicate the source of the contributions from the kinetic and potential parts of the action (4.534), respectively. Since the action is the difference between kinetic and potential energy, the average potential energy is minus twice as big as the kinetic energy, which is the single-particle version of the virial theorem observed in the Thomas-Fermi approximation (4.428).

For positive energies E , the eccentricity is $\epsilon > 1$ and the orbit is a hyperbola (see Fig. 4.3). Then equations (4.529)–(4.532) become

$$r = a(\epsilon \cosh \xi - 1), \quad t = \frac{a}{v_a}(\xi - \epsilon \sin \xi), \quad (4.546)$$

$$x = -a\epsilon(\cosh \xi - \epsilon), \quad y = a\sqrt{\epsilon^2 - 1} \sinh \xi. \quad (4.547)$$

The orbits take a simple form in momentum space. Using Eq. (4.506), we find from (4.524):

$$p_x = -\frac{l}{h}[\epsilon + \sin(\phi - \phi_0)], \quad p_y = \frac{l}{h}\cos(\phi - \phi_0). \quad (4.548)$$

As a function of time, the momenta describe a circle of radius

$$p_0 = \frac{l}{h} = \frac{Me^2}{l} = \frac{\bar{p}_E}{\sqrt{1 - \epsilon^2}} \quad (4.549)$$

around a center on the p_y -axis with (see Fig. 4.4)

$$p_x^c = -\frac{l}{h}\epsilon = -\frac{\epsilon}{\sqrt{1 - \epsilon^2}}. \quad (4.550)$$

Figure 4.4 Circular orbits in momentum space in units \bar{p}_E for $E < 0$ and p_E for $E > 0$.

For positive energies, the above solutions can be used to describe the scattering of electrons or ions on a central atom. For helium nuclei obtained by α -decay of radioactive atoms, this is the famous *Rutherford scattering* process. The potential is then repulsive, and e^2 in the potential (4.504) must be replaced by $-2Ze^2$, where $2e$ is the charge of the projectiles and Ze the charge of the central atom. As we can see on Fig. 4.5, the trajectories in an attractive potential are simply related to those in a repulsive potential. The momentum \bar{p}_E is the asymptotic momentum of the projectile, and may be called p_∞ . The impact parameter b of the projectile fixes the angular momentum via

$$l = bp_\infty = b\bar{p}_E. \quad (4.551)$$

Inserting l and \bar{p}_E we see that b coincides with the previous parameter b .

The relation of the impact parameter b with the scattering angle θ may be taken from Fig. 4.5, which shows that (see also Fig. 4.4)

$$\tan \frac{\theta}{2} = \frac{p_0}{p_\infty} = \frac{1}{\epsilon^2 - 1}. \tag{4.552}$$

Thus we have

$$b = a \cot \frac{\theta}{2}. \tag{4.553}$$

The particles impinging into a circular annulus of radii b and $b + db$ come out between the angles θ and $\theta + d\theta$, with $db/d\theta = -a/2 \sin^2(\theta/2)$. The area of the annulus $d\sigma = 2\pi b db$ is the differential cross section for this scattering process. The absolute ratio with respect to the associated solid angle $d\Omega \equiv 2\pi \sin \theta d\theta$ is then

$$\frac{d\sigma}{d\Omega} = \frac{b}{\sin \theta} \left| \frac{db}{d\theta} \right| = \frac{a^2}{4 \sin^4(\theta/2)} = \frac{Z^2 \alpha^2 M^2}{4 p_\infty^4 \sin^4(\theta/2)}. \tag{4.554}$$

The right-hand side is the famous *Rutherford formula*, which arises after expressing a in terms of the incoming momentum p_∞ [recall (4.526)] as $a = Ze^2/2E = Z\alpha\hbar cM/p_\infty^2$.

Figure 4.5 Geometry of scattering in momentum space. The solid curves are for attractive Coulomb potential, the dashed curves for repulsive (Rutherford scattering). The right-hand part of the figure shows the circle on which the momentum moves from \mathbf{p}_a to \mathbf{p}_b as the angle ϕ runs from ϕ_a to ϕ_b . The distance b is the impact parameter, and θ is the scattering angle.

Let us also calculate the classical eikonal in momentum space. We shall do this for the attractive interaction at positive energy. Inserting (4.524) and (4.548) we have

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = -l \int_{\phi_a}^{\phi_b} \frac{d\phi}{1 + \epsilon(\phi - \phi_0)}. \quad (4.555)$$

Using the formula¹⁶

$$\int \frac{d\xi}{1 + \epsilon \cos \xi} = \frac{2}{\sqrt{\epsilon^2 - 1}} \log \frac{1 + \epsilon + \sqrt{\epsilon^2 - 1} \tan(\xi/2)}{1 - \epsilon - \sqrt{\epsilon^2 - 1} \tan(\xi/2)}. \quad (4.556)$$

Inserting $l/\sqrt{1 - \epsilon^2} = Mv_a a = Me^2/p_\infty$, we find after some algebra

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = -\frac{Me^2}{p_\infty} \log \frac{\zeta + 1}{\zeta - 1}, \quad p_\infty = \sqrt{2ME}, \quad (4.557)$$

with

$$\zeta \equiv \sqrt{1 + \frac{(p_b^2 - p_\infty^2)(p_b^2 - p_\infty^2)}{p_\infty^2 |\mathbf{p}_b - \mathbf{p}_a|^2}}. \quad (4.558)$$

The expression (4.557) has no definite limit if the impinging particle comes in from spatial infinity where p_a becomes equal to p_∞ . There is a logarithmic divergence which is due to the infinite range of the Coulomb potential. In nature, the charges are always screened at some finite radius R , after which the logarithmic divergence disappears. This was discussed before when deriving the eikonal approximation (1.502) to Coulomb scattering.

There is a simple geometric meaning to the quantity ζ . Since the force is central, the change in momentum along a classical orbit is always in the direction of the center, so that (4.555) can also be written as

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = - \int_{\mathbf{p}_a}^{\mathbf{p}_b} r dp. \quad (4.559)$$

Expressing r in terms of momentum and total energy, this becomes for an attractive (repulsive) potential

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = \pm 2Me^2 \int_{\mathbf{p}_a}^{\mathbf{p}_b} \frac{dp}{p^2 - 2ME}. \quad (4.560)$$

Now we observe, that for $E < 0$, the integrand is the arc length on a sphere of radius $1/\bar{p}_E$ in a four-dimensional momentum space. Indeed, the three-dimensional momentum space can be mapped onto the surface of a four-dimensional unit sphere by the following transformation

$$n_4 \equiv \frac{p^2 - \bar{p}_E^2}{p^2 + \bar{p}_E^2}, \quad \mathbf{n} \equiv \frac{2\bar{p}_E \mathbf{p}}{p^2 + \bar{p}_E^2}. \quad (4.561)$$

¹⁶See the previous footnote.

Then we find that

$$\frac{dp}{p^2 + \bar{p}_E^2} = \frac{d\vartheta}{2\bar{p}_E}, \quad (4.562)$$

where $d\vartheta$ is the infinitesimal arc length on the unit sphere. But then the eikonal becomes simply

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = \pm \frac{2Me^2}{\bar{p}_E} \vartheta_{ba}, \quad (4.563)$$

where ϑ is the angular difference between the images of the momenta \mathbf{p}_b and \mathbf{p}_a . This is easily calculated. From (4.561) we find directly

$$\cos \vartheta_{ba} = \frac{4\bar{p}_E^2 \mathbf{p}_b \cdot \mathbf{p}_a + (p_b^2 - \bar{p}_E^2)(p_a^2 - \bar{p}_E^2)}{(p_b^2 + \bar{p}_E^2)(p_a^2 + \bar{p}_E^2)} = 1 - 2 \frac{\bar{p}_E^2 (\mathbf{p}_b - \mathbf{p}_a)^2}{(p_b^2 + \bar{p}_E^2)(p_a^2 + \bar{p}_E^2)}. \quad (4.564)$$

Continuing E analytically to positive energies, we may replace \bar{p}_E by $ip_\infty = 2ME$, and obtain

$$\cos \vartheta_{ba} = 1 + 2 \frac{p_\infty^2 (\mathbf{p}_b - \mathbf{p}_a)^2}{(p_b^2 - p_\infty^2)(p_a^2 - p_\infty^2)}. \quad (4.565)$$

Hence ϑ becomes imaginary, $\vartheta = i\bar{\vartheta}$, with

$$\sin \frac{\bar{\vartheta}}{2} = \frac{p_\infty^2 (\mathbf{p}_b - \mathbf{p}_a)^2}{(p_b^2 - p_\infty^2)(p_a^2 - p_\infty^2)}, \quad (4.566)$$

and the eikonal function (4.567) takes the form

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = \pm \frac{2Me^2}{p_\infty} \bar{\vartheta}_{ba}. \quad (4.567)$$

This is precisely the expression (4.557) with $\zeta = 1/\tanh(\bar{\vartheta}_{ab}/2)$.

4.12 Semiclassical Scattering

Let us also derive the semiclassical limit for the scattering amplitude.

4.12.1 General Formulation

Consider a particle impinging with a momentum \mathbf{p}_a and energy $E = E_a = \mathbf{p}_a^2/2M$ upon a nonzero potential concentrated around the origin. After a long time, it will be found far from the potential with some momentum \mathbf{p}_b and the same energy $E = E_b = \mathbf{p}_b^2/2M$. Let us derive the scattering amplitude for such a process from the heuristic formula (1.510):

$$f_{\mathbf{p}_b \mathbf{p}_a} = \frac{p_b}{M} \frac{\sqrt{2\pi\hbar M/i}^3}{(2\pi\hbar)^3} \lim_{t_b \rightarrow \infty} \frac{1}{t_b^{1/2}} e^{iE_b(t_b - t_a)/\hbar} [(\mathbf{p}_b t_b | \mathbf{p}_a t_a) - \langle \mathbf{p}_b | \mathbf{p}_a \rangle]. \quad (4.568)$$

In the semiclassical approximation we replace the exact propagator in the momentum representation by a sum over all classical trajectories and associated phases,

connecting \mathbf{p}_a to \mathbf{p}_b in the time $t_b - t_a$. According to formula (4.172) we have in three dimensions

$$\langle \mathbf{p}_b t_b | \mathbf{p}_a t_a \rangle - \langle \mathbf{p}_b | \mathbf{p}_a \rangle = \frac{(2\pi\hbar)^3}{(2\pi\hbar/i)^{3/2}} \sum'_{\text{class. traj.}} \left| \det \left(-\frac{\partial \mathbf{x}_a}{\partial \mathbf{p}_b} \right) \right|^{1/2} e^{iA(\mathbf{p}_b, \mathbf{p}_a; t_b - t_a)/\hbar - i\nu\pi\hbar/2}. \quad (4.569)$$

The sum carries a prime to indicate that unscattered trajectories are omitted. The classical action in momentum space is

$$A(\mathbf{p}_b, \mathbf{p}_a; t_b - t_a) = \int_{\mathbf{p}_b}^{\mathbf{p}_a} \mathbf{x} \cdot \dot{\mathbf{p}} - \int_{t_a}^{t_b} H dt = S(\mathbf{p}_b, \mathbf{p}_a; E) - E(t_b - t_a), \quad (4.570)$$

where $S(\mathbf{p}_b, \mathbf{p}_a; E)$ is the eikonal function introduced in Eqs. (4.240) and (4.68).

Inserting (4.569) into (1.510) we obtain the semiclassical scattering transition amplitude

$$f_{\mathbf{p}_b \mathbf{p}_a} = \lim_{t_b \rightarrow \infty} \sum'_{\text{class. traj.}} \frac{p_b}{\sqrt{t_b M}} \left| \det \frac{\partial \mathbf{x}_a}{\partial \mathbf{p}_b} \right|^{1/2} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E)/\hbar - i\nu\pi/2}. \quad (4.571)$$

The determinant has a simple physical meaning. To see this we rewrite

$$\left. \frac{\partial \mathbf{x}_a}{\partial \mathbf{p}_b} \right|_{\mathbf{p}_a} = \left. \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \right|_{\mathbf{p}_a}^{-1}, \quad (4.572)$$

so that (4.573) becomes

$$f_{\mathbf{p}_b \mathbf{p}_a} = \lim_{t_b \rightarrow \infty} \sum'_{\text{class. traj.}} \frac{p}{\sqrt{t_b M}} \left| \det \frac{\partial \mathbf{p}_b}{\partial \mathbf{x}_a} \right|_{\mathbf{p}_a}^{-1/2} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E)/\hbar - i\nu\pi/2}. \quad (4.573)$$

We now note that for large t_b

$$\mathbf{p}_b = \mathbf{p}(t_b) = M \mathbf{x}_b(t_b)/t_b \quad (4.574)$$

along any trajectory. Thus we find

$$f_{\mathbf{p}_b \mathbf{p}_a} = \lim_{t_b \rightarrow \infty} \sum'_{\text{class. traj.}} r_b \left| \det \frac{\partial \mathbf{x}_b}{\partial \mathbf{x}_a} \right|_{\mathbf{p}_a}^{-1/2} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E)/\hbar - i\nu\pi/2}, \quad (4.575)$$

where $r_b = |\mathbf{x}_b|$.

From the definition of the scattering amplitude (1.497) we expect the prefactor of the exponential to be equal to the square root of the classical differential cross section $d\sigma_{\text{cl}}/d\Omega$. Let us choose convenient coordinates in which the particle trajectories start out at a point with cartesian coordinates $\mathbf{x}_a = (x_a, y_a, z_a)$ with a large negative z_a and a momentum $\mathbf{p}_a \approx p_a \hat{\mathbf{z}}$, where $\hat{\mathbf{z}}$ is the direction of the z -axis. The final points \mathbf{x}_b of the trajectories will be described in spherical coordinates. If $\hat{\mathbf{p}}_b =$

$(\sin \theta_b \cos \phi_b, \sin \theta_b \sin \phi_b, \cos \theta_b)$ denotes the direction of the final momentum $\mathbf{p}_b = p_b \hat{\mathbf{p}}_b$, then $\mathbf{x}_b = r_b \hat{\mathbf{p}}_b$. Let us introduce an auxiliary triplet of spherical coordinates $\mathbf{s}_b \equiv (r_b, \theta_b, \phi_b)$. Then we factorize the determinant in (4.575) as

$$\det \frac{\partial \mathbf{x}_b}{\partial \mathbf{x}_a} = \det \frac{\partial \mathbf{x}_b}{\partial \mathbf{s}_a} \times \det \frac{\partial \mathbf{s}_b}{\partial \mathbf{x}_a} = r_b^2 \det \frac{\partial \mathbf{s}_b}{\partial \mathbf{x}_a}.$$

We further calculate

$$\det \frac{\partial \mathbf{s}_b}{\partial \mathbf{x}_a} = \begin{pmatrix} \frac{\partial r_b}{\partial x_a} & \frac{\partial r_b}{\partial y_a} & \frac{\partial r_b}{\partial z_a} \\ \frac{\partial \theta_b}{\partial x_a} & \frac{\partial \theta_b}{\partial y_a} & \frac{\partial \theta_b}{\partial z_a} \\ \frac{\partial \phi_b}{\partial x_a} & \frac{\partial \phi_b}{\partial y_a} & \frac{\partial \phi_b}{\partial z_a} \end{pmatrix}. \quad (4.576)$$

Long after the collision, for $t_b \rightarrow \infty$, a small change of the starting point *along* the trajectory dz_a will not affect the scattering angle. Thus we may approximate the matrix elements in the third column by $\partial z_a \approx \partial \phi / \partial z_a \approx 0$. After the same amount of time the particle will only wind up at a slightly more distant r_b , where $dr_b \approx dz_b$. Thus we may replace the matrix element in the right upper corner by 1, so that the determinant (4.576) becomes in the limit

$$\lim_{t_b \rightarrow \infty} \det \frac{\partial \mathbf{s}_b}{\partial \mathbf{x}_a} \approx \det \begin{pmatrix} \frac{\partial \theta_b}{\partial x_a} & \frac{\partial \theta_b}{\partial y_a} \\ \frac{\partial \phi_b}{\partial x_a} & \frac{\partial \phi_b}{\partial y_a} \end{pmatrix} = \frac{d\theta_b d\phi_b}{dx_b dy_b} = \frac{d\Omega}{d\sigma}, \quad (4.577)$$

where $d\Omega = \sin \theta_b d\theta d\phi_b$ is the element of the solid angle of the emerging trajectories, and $d\sigma$ the area element in the $x - y$ -plane, for which the trajectories arrive in an element of the final solid angle $d\Omega$. Thus we obtain

$$\left[\det \frac{\partial \mathbf{x}_b}{\partial \mathbf{x}_a} \right]^{-1} \approx \frac{1}{r_b^2} \frac{d\sigma}{d\Omega}. \quad (4.578)$$

The ratio $d\sigma/d\Omega$ is precisely the classical differential cross section of the scattering process.

Combining (4.575) and (4.577), we see that the contribution of an individual trajectory to the semiclassical amplitude is of the expected form [7]

$$f_{\mathbf{p}_b \mathbf{p}_a} = \sqrt{\frac{d\sigma_{\text{cl}}}{d\Omega}} \times \sum'_{\text{class. traj.}} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E)/\hbar - i\nu\pi/2}. \quad (4.579)$$

Note that this equation is also valid for some potentials which are not restricted to a finite regime around the origin, such as the Coulomb potentials. In the operator theory of quantum-mechanical scattering processes, such potentials always cause considerable problems since the outgoing wave functions remain distorted even at large distances from the scattering center.

Usually, there are only a few trajectories contributing to a process with a given scattering angle. If the actions of these trajectories differ by less than \hbar , the semiclassical approximation fails since the fluctuation integrals overlap. Examples are the light scattering causing the ordinary rainbow in nature, and glory effects seen at night around the moonlight.

We now turn to a derivation of the amplitude (4.579) from the more reliable formula (1.531) for the interacting wave function

$$\langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle = \lim_{t_a \rightarrow -\infty} \left(\frac{-2\pi i \hbar t_a}{M} \right)^{3/2} (\mathbf{x}_b t_b | \mathbf{x}_a t_a) e^{i(\mathbf{p}_a \mathbf{x}_a - p_a^2 t_a / 2M) / \hbar} \Big|_{\mathbf{x}_a = \mathbf{p}_a t_a / M},$$

by isolating the factor of $e^{ip_a r_b} / r_b$ for large r_b , as discussed at the end of Section 1.16. On the right-hand side we now insert the x -space form (4.127) of the semiclassical amplitude, and use (4.87) to write

$$\begin{aligned} \langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle &= \lim_{t_a \rightarrow -\infty} \left(\frac{-t_a}{M} \right)^{3/2} \left[\det_3 \left(-\frac{\partial \mathbf{p}_a}{\partial \mathbf{x}_b} \right) \right]^{1/2} \\ &\times e^{i[S(\mathbf{x}_b, \mathbf{x}_a; E_a) + i\mathbf{p}_a \mathbf{x}_a - i\nu\pi/2] / \hbar} \Big|_{\mathbf{x}_a = \mathbf{p}_a t_a / M}. \end{aligned} \quad (4.580)$$

Now we observe that

$$\left(\frac{-t_a}{M} \right)^{3/2} \left[\det_3 \left(-\frac{\partial \mathbf{p}_a}{\partial \mathbf{x}_b} \right) \right]^{1/2} = \left[\det_3 \left(\frac{\partial \mathbf{x}_a}{\partial \mathbf{x}_b} \right) \right]^{1/2}. \quad (4.581)$$

In Eq. (4.578) we have found that this determinant is equal to $\sqrt{d\sigma/d\Omega} / r_b$, bringing Eq. (4.580) to the form

$$\langle \mathbf{x}_b | \hat{U}_I(0, t_a) | \mathbf{p}_a \rangle = \lim_{t_a \rightarrow -\infty} \frac{1}{r_b} \sqrt{\frac{d\sigma_{\text{cl}}}{d\Omega}} e^{i[S(\mathbf{x}_b, \mathbf{x}_a; E_a) + i\mathbf{p}_a \mathbf{x}_a - i\nu\pi/2] / \hbar} \Big|_{\mathbf{x}_a = \mathbf{p}_a t_a / M}. \quad (4.582)$$

For large \mathbf{x}_b in the direction of the final momentum \mathbf{p}_b , we can rewrite the exponent as [recalling (4.240)]

$$S(\mathbf{x}_b, \mathbf{x}_a; E_a) + i\mathbf{p}_a \mathbf{x}_a = p_b r_b + S(\mathbf{p}_b, \mathbf{p}_a; E_a) \quad (4.583)$$

so that (4.582) consists of an outgoing spherical wave function $e^{ip_b r_b / \hbar} / r_b$ multiplied by the scattering amplitude

$$f_{\mathbf{p}_b \mathbf{p}_a} = \sqrt{\frac{d\sigma_{\text{cl}}}{d\Omega}} \times \sum'_{\text{class. traj.}} e^{iS(\mathbf{p}_b, \mathbf{p}_a; E) / \hbar - i\nu\pi/2}, \quad (4.584)$$

the same as in (4.579).

4.12.2 Semiclassical Cross Section of Mott Scattering

If the scattering particle is distinguishable from the target particles, the extra phase in the semiclassical formula (4.584) does not change the classical result (4.554). A quantum-mechanical effect becomes visible only if we consider electron-electron scattering, also referred to as *Mott scattering*. The potential is repulsive, and the above Coulomb potential holds for the relative motion of the two identical particles in their center-of-mass frame. Moreover, the identity of particles requires us to add the amplitudes for the trajectories going to \mathbf{p}_b and to $-\mathbf{p}_b$ [see Fig. 4.6], so that the differential cross section is

$$\frac{d\sigma_{sc}}{d\Omega} = |f_{\mathbf{p}_b, \mathbf{p}_a} - f_{\mathbf{p}_b, -\mathbf{p}_a}|^2. \quad (4.585)$$

The minus sign accounts for the Fermi statistics of the two electrons. For two identical bosons, we have to use a plus sign instead. Now the eikonal function $S(\mathbf{p}, \mathbf{p}, E)$ enters into the result. According to Eq. (4.557), this is given by

Figure 4.6 Classical trajectories in Coulomb potential plotted in the center-of-mass frame. For identical particles, trajectories which merge with a scattering angle θ and $\pi - \theta$ are indistinguishable. Their amplitudes must be subtracted from each other, yielding the differential cross section (4.585).

$$S(\mathbf{p}_b, \mathbf{p}_a; E) = -\frac{M\hbar c\alpha}{p_\infty} \log \frac{\sqrt{1 + \Delta} + 1}{\sqrt{1 + \Delta} - 1}, \quad (4.586)$$

where $p_\infty = \sqrt{2ME}$ is the impinging momentum at infinite distance, and

$$\Delta \equiv \frac{(p_b^2 - p_\infty^2)(p_a^2 - p_\infty^2)}{p_\infty^2 |\mathbf{p}_b - \mathbf{p}_a|^2}. \quad (4.587)$$

The eikonal function is needed only for momenta $\mathbf{p}_b, \mathbf{p}_a$ in the asymptotic regime where $p_b, p_a \approx p_\infty$, so that Δ is small and

$$S(\mathbf{p}_b, \mathbf{p}_a; E) \approx \frac{M\hbar c\alpha}{p_\infty} \log \Delta, \quad (4.588)$$

which may be rewritten as

$$S(\mathbf{p}, \mathbf{p}_a E) \approx 2\sigma_0 - \frac{M\hbar c\alpha}{p_\infty} \log(\sin^2 \theta/2), \quad (4.589)$$

with

$$\sigma_0 = \frac{M\hbar c\alpha}{2p_\infty} \log \left[\frac{(p_b^2 - p_\infty^2)(p_a^2 - p_\infty^2)}{p_\infty^4} \right], \quad (4.590)$$

and the scattering angle determined by $\cos \theta = [\mathbf{p}_b \cdot \mathbf{p}_a / p_b p_a]$. The logarithmically diverging constant σ_0 for $p_a = p_b p_\infty$ does, fortunately, not depend on the scattering angle, and is therefore the semiclassical approximation for the phase shift at angular momentum $l = 0$. It therefore drops, fortunately, out of the difference of the amplitudes in Eq. (4.585). Inserting (4.589) with (4.590) into (4.584) and (4.585), we obtain the differential cross section for Mott scattering (see Fig. 4.7 for a plot)

$$\frac{d\sigma}{d\Omega} = \left(\frac{\hbar c\alpha}{4E} \right)^2 \left\{ \frac{1}{\sin^4 \theta/2} + \frac{1}{\cos^4 \theta/2} \pm \frac{1}{\sin^2 \theta/2 \cos^2 \theta/2} 2 \cos \left[\frac{2\alpha M c}{p_\infty} \log(\cot \theta/2) \right] \right\}. \quad (4.591)$$

This semiclassical result happens to be identical to the exact result. The exactness is caused by two properties of the Coulomb motion: First there is only one trajectory for each scattering angle, second the motion can be mapped onto that of a harmonic oscillator in four dimensions, as we shall see in Chapter 13.

Figure 4.7 Oscillations in differential Mott scattering cross section caused by statistics. For scattering angle $\theta = 90^\circ$, the cross section vanishes due to the Pauli exclusion principle. The right-hand plot shows the situation for identical bosons.

Appendix 4A Semiclassical Quantization for Pure Power Potentials

Let us calculate the local density of states (4.264) for the general pure power potential $V(\mathbf{x}) = gx^p/p$ in D dimensions. For $D = 1$ and $p = 2$, we shall recover the exact spectrum of the harmonic oscillator. For $p = 4$, we shall find the energies of the purely quartic potential which can be compared with the strong-coupling limit of the anharmonic oscillator with $V(x) = \omega^2 x^2/2 + gx^4/4$ to be calculated in Section 5.16. The integrals on the right-hand side of Eq. (4.264) can be calculated using the formula

$$\int d^D x r^\mu [E - V(\mathbf{x})]^\nu = S_D \int_0^{r^E} dr r^{D-1+\mu} \left(E - \frac{g}{p} r^p \right)^\nu$$

$$= S_D \frac{\Gamma(1+\nu)\Gamma((D+\mu)/p)}{p\Gamma(1+\nu+(D+\mu)/p)} \left(\frac{g}{p}\right)^{-(D+\mu)/p} E^{\nu+(D+\mu)/p}, \quad p > 0, \quad (4A.1)$$

where $r_E = (pE/g)^{1/p}$. For $p < 0$, the result is

$$\int d^D x r^\mu [E - V(\mathbf{x})]^\nu = S_D \frac{\Gamma(1+\nu)\Gamma(-\nu-(D+\mu)/p)}{p\Gamma(1-(D+\mu)/p)} \left(-\frac{g}{p}\right)^{-(D+\mu)/p} (-E)^{\nu+(D+\mu)/p}, \quad p < 0. \quad (4A.2)$$

Recalling (4.214), we find the total density of states for $p > 0$:

$$\begin{aligned} \rho(E) &= \frac{2}{\Gamma(\frac{D}{2})p} \left(\frac{M}{2\hbar^2}\right)^{D/2} \left(\frac{g}{p}\right)^{-D/p} \frac{\Gamma(\frac{D}{p})}{\Gamma(\frac{D}{2} + \frac{D}{p})} \left\{ 1 - \frac{\hbar^2}{24M} \left(\frac{g}{p}\right)^{2/p} \right. \\ &\quad \left. \times \frac{p^2 \Gamma(\frac{D-2}{p} + 2) \Gamma(\frac{D}{2} + \frac{D}{p})}{\Gamma(\frac{D-2}{2}(1 + \frac{2}{p}) \Gamma(\frac{D}{p})} E^{-1-2/p} + \dots \right\} E^{(D/2)(1+2/p)-1}, \quad p > 0, \end{aligned} \quad (4A.3)$$

and for $p < 0$:

$$\begin{aligned} \rho(E) &= -\frac{2}{\Gamma(\frac{D}{2})p} \left(\frac{M}{2\hbar^2}\right)^{D/2} \left(-\frac{g}{p}\right)^{-D/p} \frac{\Gamma(1 - \frac{D}{2} - \frac{D}{p})}{\Gamma(1 - \frac{D}{p})} \left\{ 1 + \frac{\hbar^2}{24M} \left(-\frac{g}{p}\right)^{2/p} \right. \\ &\quad \left. \times \frac{p^2 \Gamma(1 - \frac{D-2}{2}(1 + \frac{2}{p})) \Gamma(1 - \frac{D}{p})}{\Gamma(-1 - \frac{D-2}{p}) \Gamma(1 - \frac{D}{2} - \frac{D}{p})} (-E)^{-1-2/p} + \dots \right\} (-E)^{(D/2)(1+2/p)-1}, \quad p < 0. \end{aligned} \quad (4A.4)$$

For a harmonic oscillator with $p = 2$ and $g = M\omega^2$, we obtain

$$\rho(E) = \frac{1}{(\hbar\omega)^D} \left\{ \frac{1}{\Gamma(D)} E^{D-1} - \frac{\hbar^2\omega^2}{24} \frac{D}{\Gamma(D-2)} E^{D-3} + \dots \right\}. \quad (4A.5)$$

In one and two dimension, only the first term survives and $\rho(E) = 1/\hbar\omega$ or $\rho(E) = E/(\hbar\omega)^2$. Inserting this into Eq. (1.586), we find the number of states $N(E) = \int_0^E dE' \rho(E') = E/\hbar\omega$ or $E^2/2(\hbar\omega)^2$. According to the exact quantization condition (1.588), we set $N(E) = n + 1/2$ the exact energies $E_n = (n + 1/2)\hbar\omega$. Since the semiclassical expansion (4A.3) contains only the first term, the exact quantization condition (1.588) agrees with the Bohr-Sommerfeld quantization condition (4.190).

In two dimensions we obtain $\rho(E) = E/(\hbar\omega)^2$ and $N(E) = E^2/2(\hbar\omega)^2$. Here the exact quantization condition $N(E) = n + 1/2$ cannot be used to find the energies E_n , due to the degeneracies of the energy eigenvalues E_n . In order to see that it is nevertheless a true equation, let us expand the known partition function (2.407) of the two-dimensional oscillator as

$$Z = \frac{1}{[2 \sinh(\hbar\beta\omega/2)]^2} = e^{-\hbar\beta\omega} \frac{1}{(1 - e^{-\hbar\beta\omega})^2} = \sum_{n=0}^{\infty} (n+1) e^{-(n+1)\hbar\beta\omega}. \quad (4A.6)$$

This shows that the energies are $E_n = (n + 1)\hbar\omega$ with $n + 1$ -fold degeneracy. The density of states is found from this by the Fourier transform (1.585):

$$\rho(E) = \sum_{n'=0}^{\infty} (n'+1) \delta(E - \hbar\omega(n'+1)). \quad (4A.7)$$

Integrating this over E yields the number of states

$$N(E) = \int_0^E dE' \rho(E') = \sum_{n'=0}^{\infty} (n'+1) \Theta(E - E_n). \quad (4A.8)$$

For $E = E_n$ this becomes [recall (1.313)]

$$N(E_n) = \sum_{n'=0}^{n-1} (n'+1) + (n+1) \frac{1}{2} = \frac{1}{2}(n+1)^2. \quad (4A.9)$$

This shows that the exact energies $E_n = (n+1)\hbar\omega$ of the two-dimensional oscillator satisfy the quantization condition $N(E_n) = (n+1)^2/2$ rather than (1.588).

For a quartic potential $gx^4/4$, Eq. (4A.3) becomes

$$\rho(E) = \frac{1}{2\Gamma(\frac{D}{2})\Gamma(\frac{3D}{4})} \left(\frac{g\hbar^4}{M^2}\right)^{-\frac{E}{4}} \left\{ 1 - \left(\frac{g\hbar^4}{M^2}\right)^{\frac{1}{2}} \frac{\Gamma(\frac{3}{2} + \frac{D}{4})\Gamma(\frac{3D}{4})E^{-\frac{3}{2}}}{3\Gamma(\frac{D}{4})\Gamma(\frac{3}{4}(D-2))} + \dots \right\} E^{\frac{3D}{4}-1}. \quad (4A.10)$$

Integrating this over E yields $N(E)$. Setting $N(E) = n + 1/2$ in one dimension, we obtain the Bohr-Sommerfeld energies (4.35) plus a first quantum correction. Since we have studied these corrections to high order in Subsection 4.9.6 (see Fig. 4.1), we do not write the result down here.

A physically important case is $p = -1$, $g = \hbar c\alpha$, with α of Eq. (1.505), where $V(x) = -\hbar c\alpha/r$ becomes the Coulomb potential. Here we obtain from (4A.10):

$$\rho(E) = \frac{2}{\Gamma(\frac{D}{2})} \left(\frac{Mg^2}{2\pi\hbar^2}\right)^{D/2} \frac{\Gamma(1 + \frac{D}{2})}{\Gamma(1 + D)} \times \left\{ 1 - \frac{\hbar^2}{24Mg^{-2}} \frac{p^2 \Gamma(\frac{D-2}{2}) \Gamma(1 + D)}{\Gamma(D-3) \Gamma(1 + \frac{D}{2})} E + \dots \right\} (-E)^{(D/2)(1+2/p)-1}. \quad (4A.11)$$

For $D = 1$, only the leading term survives and

$$\rho(E) = \sqrt{\frac{Mg^2}{2\hbar^2}} (-E)^{-3/2}, \quad (4A.12)$$

implying that

$$N(E) = 2\sqrt{\frac{Mg^2}{2\hbar^2}} (-E)^{-1/2}. \quad (4A.13)$$

In order to find the bound-state energies, we must watch out for a subtlety in one dimension: only the positive half-space is accessible to the particle in a Coulomb potential, due to the strong singularity at the origin. For this reason, the “surface of a sphere” S_D for $D = 1$, which is equal to 2, must be replaced by 1, so that we must equate $N(E)/2$ to $n + 1/2$. This yields the spectrum $E_n = -\alpha^2 M c^2 / 2(n + 1/2)^2$. The exact energies follow the same formula with n^2 instead of $(n + 1/2)^2$ [7]. In contrast to the harmonic oscillator, the Bohr-Sommerfeld approximation yields here the correct energies only for large n . We have seen at the end of Section 4.1 how to correct this defect: we must go to a new variable ξ by the coordinate transformation $r = e^\xi$. This moves the singularity at $r = 0$ to $\xi = -\infty$ and the semiclassical result becomes *exact*.

Appendix 4B Derivation of Semiclassical Time Evolution Amplitude

Here we derive the semiclassical approximation to the time evolution amplitude (4.267). We shall do this for imaginary times $\tau = it$. Decomposing the path $\mathbf{x}(\tau)$ into path average of the ends points $\bar{\mathbf{x}} = (\mathbf{x}_b + \mathbf{x}_a)/2$ and fluctuations $\boldsymbol{\eta}(\tau)$, we calculate the imaginary-time amplitude¹⁷

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \int_{\boldsymbol{\eta}(\tau_a) = -\Delta\mathbf{x}/2}^{\boldsymbol{\eta}(\tau_b) = \Delta\mathbf{x}/2} \mathcal{D}\boldsymbol{\eta} \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{\boldsymbol{\eta}}^2(\tau) + V(\bar{\mathbf{x}} + \boldsymbol{\eta}(\tau)) \right] \right\}, \quad (4B.1)$$

¹⁷In the mathematical literature this is a heat kernel (see Footnote 16 in Chapter 2). The expansions in (4B.16) and (4B.59) are called a *heat kernel expansions*, or *Hadamard expansions*, crediting J. Hadamard, *Lectures on Cauchy's Problem*, Yale University Press, New Haven, 1932.

where $\Delta \mathbf{x} \equiv \mathbf{x}_b - \mathbf{x}_a$. For smooth potentials we expand

$$V(\bar{\mathbf{x}} + \boldsymbol{\eta}(\tau)) = V(\bar{\mathbf{x}}) + \partial_i V(\bar{\mathbf{x}}) \eta_i(\tau) + \frac{1}{2} \partial_i \partial_j V(\bar{\mathbf{x}}) \eta_i(\tau) \eta_j(\tau) + \dots, \quad (4B.2)$$

where $V_{ij\dots}(\bar{\mathbf{x}}) \equiv \partial_i \partial_j \dots V(\bar{\mathbf{x}})$, and rewrite the path integral (4B.1) as

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &= e^{-\beta V(\bar{\mathbf{x}})} \int_{\boldsymbol{\eta}(\tau_a) = -\Delta \mathbf{x}/2}^{\boldsymbol{\eta}(\tau_b) = \Delta \mathbf{x}/2} \mathcal{D}\boldsymbol{\eta} \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \frac{M}{2} \dot{\boldsymbol{\eta}}^2(\tau) \right\} \\ &\times \left\{ 1 - \frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left[V_i(\bar{\mathbf{x}}) \eta_i(\tau) + \frac{1}{2} V_{ij}(\bar{\mathbf{x}}) \eta_i(\tau) \eta_j(\tau) + \dots \right] \right. \\ &\left. + \frac{1}{2\hbar^2} \int_{\tau_a}^{\tau_b} d\tau \int_{\tau_a}^{\tau_b} d\tau' \left[V_i(\bar{\mathbf{x}}) V_j(\bar{\mathbf{x}}) \eta_i(\tau) \eta_j(\tau') + \dots \right] + \dots \right\}. \end{aligned} \quad (4B.3)$$

At this point it is useful to introduce an auxiliary harmonic imaginary-time amplitude

$$(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a) = \int_{\boldsymbol{\eta}(\tau_a) = -\Delta \mathbf{x}/2}^{\boldsymbol{\eta}(\tau_b) = \Delta \mathbf{x}/2} \mathcal{D}\boldsymbol{\eta} \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \frac{M}{2} \dot{\boldsymbol{\eta}}^2(\tau) \right\} \quad (4B.4)$$

and the harmonic expectation values

$$\langle F[\boldsymbol{\eta}] \rangle \equiv \frac{1}{(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)} \int_{\boldsymbol{\eta}(\tau_a) = -\Delta \mathbf{x}/2}^{\boldsymbol{\eta}(\tau_b) = \Delta \mathbf{x}/2} \mathcal{D}\boldsymbol{\eta} F[\boldsymbol{\eta}] \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \frac{M}{2} \dot{\boldsymbol{\eta}}^2(\tau) \right\}, \quad (4B.5)$$

which allows us to rewrite (4B.3) more concisely as

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &= e^{-\beta V(\bar{\mathbf{x}})} (\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a) \left\{ 1 - \frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau V_i(\bar{\mathbf{x}}) \langle \eta_i(\tau) \rangle \right. \\ &\left. - \frac{1}{2\hbar} V_{ij}(\bar{\mathbf{x}}) \int_{\tau_a}^{\tau_b} d\tau \langle \eta_i(\tau) \eta_j(\tau) \rangle + \frac{1}{2\hbar^2} V_i(\bar{\mathbf{x}}) V_j(\bar{\mathbf{x}}) \int_{\tau_a}^{\tau_b} d\tau \int_{\tau_a}^{\tau_b} d\tau' \langle \eta_i(\tau) \eta_j(\tau') \rangle + \dots \right\}. \end{aligned} \quad (4B.6)$$

The amplitudes (4B.4) reads explicitly, with $\Delta \tau \equiv \tau_b - \tau_a$:

$$(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a) = \left(\frac{M}{2\pi \hbar \Delta \tau} \right)^{D/2} \exp \left\{ -\frac{M}{2\hbar \Delta \tau} (\Delta \mathbf{x})^2 \right\}, \quad (4B.7)$$

and (4B.5) can be calculated from the generating functional

$$(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)[\mathbf{j}] = \int_{\boldsymbol{\eta}(\tau_a) = -\Delta \mathbf{x}/2}^{\boldsymbol{\eta}(\tau_b) = \Delta \mathbf{x}/2} \mathcal{D}\boldsymbol{\eta} \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{\boldsymbol{\eta}}^2(\tau) - \mathbf{j}(\tau) \boldsymbol{\eta}(\tau) \right] \right\}, \quad (4B.8)$$

whose explicit solution is

$$\begin{aligned} (\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)[\mathbf{j}] &= \left(\frac{M}{2\pi \hbar \Delta \tau} \right)^{D/2} \exp \left\{ -\frac{M}{2\hbar \Delta \tau} (\Delta \mathbf{x})^2 + \frac{1}{\hbar \Delta \tau} \int_{\tau_a}^{\tau_b} d\tau (\tau - \bar{\tau}) \Delta \mathbf{x} \mathbf{j}(\tau) \right. \\ &\left. + \frac{1}{2\hbar} \int_{\tau_a}^{\tau_b} d\tau \int_{\tau_a}^{\tau_b} d\tau' \frac{\Theta(\tau - \tau') (\Delta \tau - \tau) \tau' + \Theta(\tau' - \tau) (\Delta \tau - \tau') \tau}{M \Delta \tau} \mathbf{j}(\tau) \mathbf{j}(\tau') \right\}. \end{aligned}$$

The expectation values in (4B.6) and (4B.5) are obtained from the functional derivatives

$$\langle \eta_i(\tau) \rangle = \frac{1}{(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)} \frac{\hbar \delta}{\delta j_i(\tau)} (\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)[\mathbf{j}] \Big|_{\mathbf{j}=\mathbf{0}}, \quad (4B.9)$$

$$\langle \eta_i(\tau) \eta_j(\tau') \rangle = \frac{1}{(\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)} \frac{\hbar \delta}{\delta j_i(\tau)} \frac{\hbar \delta}{\delta j_j(\tau')} (\Delta \mathbf{x}/2 \tau_b | -\Delta \mathbf{x}/2 \tau_a)[\mathbf{j}] \Big|_{\mathbf{j}=\mathbf{0}}. \quad (4B.10)$$

This yields the $\Delta\mathbf{x}$ -dependent expectation value

$$\langle \eta_i(\tau) \rangle = (\tau - \bar{\tau}) \frac{\Delta x_i}{\Delta\tau}, \quad (4B.11)$$

and the $\Delta\mathbf{x}$ -dependent correlation function

$$\begin{aligned} \langle \eta_i(\tau) \eta_j(\tau') \rangle &= \frac{\hbar}{M\Delta\tau} [\Theta(\tau - \tau')(\Delta\tau - \tau)\tau' + \Theta(\tau' - \tau)(\Delta\tau - \tau')\tau] \delta_{ij} \\ &+ (\tau - \bar{\tau})(\tau' - \bar{\tau}) \frac{\Delta x_i}{\Delta\tau} \frac{\Delta x_j}{\Delta\tau} \\ &\equiv G(\tau, \tau') \delta_{ij} + H(\tau, \tau') \Delta x_i \Delta x_j \equiv G_{ij}^{\Delta x}(\tau, \tau'). \end{aligned} \quad (4B.12)$$

Note that

$$\int_{\tau_a}^{\tau_b} d\tau \langle \eta_i(\tau) \rangle = 0, \quad (4B.13)$$

and

$$\int_{\tau_a}^{\tau_b} d\tau \int_{\tau_a}^{\tau_b} d\tau' \langle \eta_i(\tau) \eta_j(\tau') \rangle = \int_{\tau_a}^{\tau_b} d\tau \int_{\tau_a}^{\tau_b} d\tau' G_{ij}^{\Delta x}(\tau, \tau') = \frac{\hbar}{12M} \Delta\tau (\Delta\tau^2 - \tau_a^2) \delta_{ij}, \quad (4B.14)$$

$$\int_{\tau_a}^{\tau_b} d\tau \langle \eta_i(\tau) \eta_j(\tau) \rangle = \int_{\tau_a}^{\tau_b} d\tau G_{ij}^{\Delta x}(\tau, \tau) = \frac{\hbar}{M} \left[\frac{\Delta\tau^2}{6} - \tau_a^2 \right] \delta_{ij} + \frac{\Delta\tau}{12} \Delta x_i \Delta x_j. \quad (4B.15)$$

Thus we obtain the semiclassical imaginary-time amplitude

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &= \left(\frac{M}{2\pi\hbar\Delta\tau} \right)^{D/2} \exp \left\{ -\frac{M}{2\hbar\Delta\tau} \Delta\mathbf{x}^2 - \frac{\Delta\tau}{\hbar} V(\bar{\mathbf{x}}) \right\} \\ &\times \left\{ 1 - \frac{\Delta\tau^2}{12M} \nabla^2 V(\bar{\mathbf{x}}) - \frac{\Delta\tau}{24\hbar} (\Delta\mathbf{x} \nabla)^2 V(\bar{\mathbf{x}}) + \frac{\Delta\tau^3}{24M\hbar} [\nabla V(\bar{\mathbf{x}})]^2 + \dots \right\}. \end{aligned} \quad (4B.16)$$

This agrees precisely with the real-time amplitude (4.267).

For the partition function at inverse temperature $\beta = (\tau_b - \tau_a)/\hbar$, this implies the semiclassical approximation

$$\begin{aligned} Z &= \int d^D x (\mathbf{x} \hbar\beta | \mathbf{x} 0) \\ &\approx \left(\frac{M}{2\pi\hbar^2\beta} \right)^{D/2} \int d^D \bar{\mathbf{x}} \left(1 - \frac{\hbar^2\beta^2}{12M} \nabla^2 V(\mathbf{x}) + \frac{\hbar^2\beta^3}{24M} [\nabla V(\mathbf{x})]^2 \right) e^{-\beta V(\mathbf{x})}. \end{aligned} \quad (4B.17)$$

A partial integration simplifies this to

$$\begin{aligned} Z &\approx \left(\frac{M}{2\pi\hbar^2\beta} \right)^{D/2} \int d^D x \left(1 - \frac{\hbar^2\beta^2}{24M} \nabla^2 V(\mathbf{x}) \right) e^{-\beta V(\mathbf{x})} \\ &\approx \left(\frac{M}{2\pi\hbar^2\beta} \right)^{D/2} \int d^D x \exp \left(-\beta V(\mathbf{x}) - \frac{\hbar^2\beta^2}{24M} \nabla^2 V(\mathbf{x}) \right). \end{aligned} \quad (4B.18)$$

Let us also sketch how to calculate all terms in (4B.16) proportional to $V(\bar{\mathbf{x}})$ and its derivatives. Instead of the expansion (4B.6), we evaluate

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = e^{-\beta V(\bar{\mathbf{x}})} (\Delta\mathbf{x}/2 \tau_b | -\Delta\mathbf{x}/2 \tau_a) \left\{ 1 - \frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \langle V(\bar{\mathbf{x}} + \boldsymbol{\eta}(\tau)) - V(\bar{\mathbf{x}}) \rangle \right\}. \quad (4B.19)$$

By rewriting $V(\bar{\mathbf{x}} + \boldsymbol{\eta})$ as a Fourier integral

$$V(\bar{\mathbf{x}} + \boldsymbol{\eta}) = \int \frac{d^D k}{(2\pi)^D} \tilde{V}(\mathbf{k}) \exp[i\mathbf{k}(\bar{\mathbf{x}} + \boldsymbol{\eta})], \quad (4B.20)$$

we obtain

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &= (\Delta \mathbf{x} / 2 \tau_b | -\Delta \mathbf{x} / 2 \tau_a) \\ &\times e^{-\beta V(\bar{\mathbf{x}})} \left\{ 1 - \frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \int \frac{d^D k}{(2\pi)^D} \tilde{V}(\mathbf{k}) e^{i\mathbf{k}\bar{\mathbf{x}}} \langle e^{i\mathbf{k}\boldsymbol{\eta}(\tau)} - 1 \rangle \right\}. \end{aligned} \quad (4B.21)$$

The expectation value can be calculated using Wick's theorem (3.310) as

$$\int_{\tau_a}^{\tau_b} d\tau \langle e^{i\mathbf{k}\boldsymbol{\eta}(\tau)} \rangle = \int_{\tau_a}^{\tau_b} d\tau e^{-k_i k_j \langle \eta_i(\tau) \eta_j(\tau) \rangle / 2} = \int_{\tau_a}^{\tau_b} d\tau e^{-k_i k_j [G(\tau, \tau) \delta_{ij} + H(\tau, \tau) \Delta x_i \Delta x_j] / 2}. \quad (4B.22)$$

where the equal-time functions $G(\tau, \tau)$, $H(\tau, \tau)$ are from (4B.12):

$$G(\tau, \tau) = \frac{\hbar}{M \Delta \tau} (\Delta \tau - \tau), \quad H(\tau, \tau) = \frac{(\tau - \bar{\tau})^2}{\Delta \tau^2}. \quad (4B.23)$$

Inserting the inverse of the Fourier decomposition (4B.20),

$$\tilde{V}(\mathbf{k}) = \int d^D \eta V(\bar{\mathbf{x}} + \boldsymbol{\eta}) \exp[-i\mathbf{k}(\bar{\mathbf{x}} + \boldsymbol{\eta})], \quad (4B.24)$$

where $\boldsymbol{\eta}$ is now a time-independent variable of integration, we find

$$\int_{\tau_a}^{\tau_b} d\tau \langle e^{i\mathbf{k}\boldsymbol{\eta}(\tau)} \rangle = \int_{\tau_a}^{\tau_b} d\tau \int d^D \eta V(\bar{\mathbf{x}} + \boldsymbol{\eta}) \int \frac{d^D k}{(2\pi)^D} e^{-(1/2)k_i G_{ij}^{\Delta x}(\tau, \tau) k_j - i k_i \eta_i(\tau)}. \quad (4B.25)$$

After a quadratic completion of the exponent, the momentum integral can be performed and yields

$$\int_{\tau_a}^{\tau_b} d\tau \langle e^{i\mathbf{k}\boldsymbol{\eta}(\tau)} \rangle = \int d^D \eta V(\bar{\mathbf{x}} + \boldsymbol{\eta}) \int_{\tau_a}^{\tau_b} d\tau [\det G_{ij}^{\Delta x}(\tau, \tau)]^{-1/2} e^{-(1/2)\eta_i [G_{ij}^{\Delta x}(\tau, \tau)]^{-1} \eta_j}. \quad (4B.26)$$

Using the transverse and longitudinal projection matrices

$$P_{ij}^T = \delta_{ij} - \frac{\Delta x_i \Delta x_j}{(\Delta x)^2}, \quad P_{ij}^L = \frac{\Delta x_i \Delta x_j}{(\Delta x)^2}, \quad (4B.27)$$

satisfying $P^{T^2} = P^T$, $P^{L^2} = P^L$, we can decompose $G_{ij}(\tau, \tau')$ as

$$G_{ij}^{\Delta x}(\tau, \tau') \equiv G(\tau, \tau') P_{ij}^T + [G(\tau, \tau') + H(\tau, \tau') (\Delta x)^2] P_{ij}^L. \quad (4B.28)$$

It is then easy to find the determinant

$$\det G_{ij}^{\Delta x}(\tau, \tau') = [G(\tau, \tau')]^{D-1} [G(\tau, \tau') + H(\tau, \tau') (\Delta x)^2], \quad (4B.29)$$

and the inverse matrix

$$[G_{ij}^{\Delta x}(\tau, \tau')]^{-1} = \frac{1}{G(\tau, \tau')} \left[\delta_{ij} - \frac{\Delta x_i \Delta x_j}{(\Delta x)^2} \right] + \frac{1}{G(\tau, \tau') + H(\tau, \tau') (\Delta x)^2} \frac{\Delta x_i \Delta x_j}{(\Delta x)^2}. \quad (4B.30)$$

Inserting (4B.26) back into (4B.21), and taking the correction into the exponent, we arrive at

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = (\Delta \mathbf{x} / 2 \tau_b | -\Delta \mathbf{x} / 2 \tau_a) e^{-\int_{\tau_a}^{\tau_b} d\tau \bar{V}(\bar{\mathbf{x}}, \tau) / \hbar}, \quad (4B.31)$$

where $\bar{V}(\bar{\mathbf{x}}, \tau)$ is the harmonically smeared potential

$$\bar{V}(\bar{\mathbf{x}}, \tau) \equiv [\det G_{ij}^{\Delta x}(\tau, \tau)]^{-1/2} \int d^D \eta V(\bar{\mathbf{x}} + \boldsymbol{\eta}) e^{-(1/2)\eta_i [G_{ij}^{\Delta x}(\tau, \tau)]^{-1} \eta_j}. \quad (4B.32)$$

By expanding $V(\bar{\mathbf{x}} + \boldsymbol{\eta})$ to second order in $\boldsymbol{\eta}$, the exponent in (4B.31) becomes

$$-\beta V(\bar{\mathbf{x}}) - \frac{1}{2\hbar} V_{ij}(\bar{\mathbf{x}}) \int_{\tau_a}^{\tau_b} d\tau G_{ij}^{\Delta x}(\tau, \tau) + \dots \quad (4B.33)$$

According to Eq. (4B.15), we have

$$\int_{\tau_a}^{\tau_b} d\tau G_{ij}^{\Delta x}(\tau, \tau) = \frac{\hbar}{M} \frac{\Delta\tau^2}{6} \delta_{ij} + \frac{\Delta\tau}{12} \Delta x_i \Delta x_j, \quad (4B.34)$$

so that we reobtain the first two correction terms in the curly brackets of (4B.16)

The calculation of the higher-order corrections becomes quite tedious. One rewrites the expansion (4B.2) as $V(\bar{\mathbf{x}} + \boldsymbol{\eta}(\tau)) = e^{\eta_i(\tau)\partial_i} V(\bar{\mathbf{x}})$ and (4B.19) as

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = (\Delta\mathbf{x}/2\tau_b | -\Delta\mathbf{x}/2\tau_a) \times \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \left\langle \prod_{n=0}^{\infty} \int_{\tau_a}^{\tau_b} d\tau_n e^{\eta_i(\tau_n)\partial_i} V(\bar{\mathbf{x}}) \right\rangle. \quad (4B.35)$$

Now we apply Wick's rule (3.310) for harmonically fluctuating variables, to re-express

$$\begin{aligned} \langle e^{\eta(\tau)\partial_i} \rangle &= e^{\langle \eta_i(\tau)\eta_j(\tau) \rangle / 2} = e^{G_{ij}^{\Delta x}(\tau, \tau)\partial_i\partial_j/2}, \\ \langle e^{\eta_i(\tau)\partial_i} e^{\eta_i(\tau')\partial_i} \rangle &= e^{[\langle \eta_i(\tau)\eta_j(\tau) \rangle \partial_i\partial_j + \langle \eta_i(\tau')\eta_j(\tau') \rangle \partial_i\partial_j + 2\langle \eta_i(\tau)\eta_j(\tau') \rangle \partial_i\partial_j] / 2} \\ &= e^{[G_{ij}^{\Delta x}(\tau, \tau)\partial_i\partial_j + G_{ij}^{\Delta x}(\tau', \tau')\partial_i\partial_j + 2G_{ij}^{\Delta x}(\tau, \tau')\partial_i\partial_j] / 2} \\ &\vdots \end{aligned} \quad (4B.36)$$

Expanding the exponentials and performing the τ -integrals in (4B.35) yields all desired higher-order corrections in (4B.16).

For $\Delta\mathbf{x} = 0$, the expansion has been driven to high orders in Ref. [8] (including a minimal interaction with a vector potential).

There exists an efficient operator method for evaluating (4B.1) and deriving (4B.16) which goes as follows. We rewrite (4B.1) in operator form as

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \langle \mathbf{x}_b | e^{-\Delta\tau H(\hat{p}^2, \hat{\mathbf{x}})/\hbar} | \mathbf{x}_a \rangle = \langle \mathbf{x}_b | e^{-\Delta\tau[\hat{p}^2/2M + V(\hat{\mathbf{x}})]/\hbar} | \mathbf{x}_a \rangle. \quad (4B.37)$$

With the help of formula (1.296), this can be expressed as follows:

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \langle \mathbf{x}_b | e^{-\Delta\tau \hat{p}^2/2M\hbar} \hat{T} \exp \left\{ -\int_0^{\Delta\tau} d\tau e^{\tau \hat{p}^2/2M\hbar} V(\mathbf{x}) e^{-\tau \hat{p}^2/2M\hbar} \right\} | \mathbf{x}_a \rangle. \quad (4B.38)$$

Now we use the Heisenberg equation (1.277) and evaluate

$$e^{\tau \hat{p}^2/2M\hbar} V(\hat{\mathbf{x}}) e^{-\tau \hat{p}^2/2M\hbar} \equiv V(\hat{\mathbf{x}}_H(\tau)) = V(\hat{\mathbf{x}} - i\hat{\mathbf{p}}\tau/M). \quad (4B.39)$$

This allows us to recast (4B.38) to the form

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \langle \mathbf{x}_b | e^{-\Delta\tau \hat{p}^2/2M\hbar} \hat{T} \exp \left\{ -\frac{1}{\hbar} \int_0^{\Delta\tau} d\tau \Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau) \right\} | \mathbf{x}_a \rangle e^{-\Delta\tau V(\mathbf{x}_a)/\hbar}, \quad (4B.40)$$

where

$$\Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau) \equiv V(\hat{\mathbf{x}} - i\hat{\mathbf{p}}\tau/M) - V(\hat{\mathbf{x}}). \quad (4B.41)$$

Expressing $V(\hat{\mathbf{x}})$ by its Fourier representation, this is equal to

$$\Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau) = \int \frac{d^D k}{(2\pi)^D} \tilde{V}(\mathbf{k}) \left(e^{i\mathbf{k}(\hat{\mathbf{x}} - i\hat{\mathbf{p}}\tau/M)} - e^{i\mathbf{k}\hat{\mathbf{x}}} \right), \quad (4B.42)$$

which is also equal to

$$\Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau) = \int d^D x' V(\mathbf{x}') S(\hat{\mathbf{p}}\tau, \hat{\mathbf{x}}, \mathbf{x}'), \quad (4B.43)$$

where

$$S(\hat{\mathbf{p}}\tau, \hat{\mathbf{x}}, \mathbf{x}'; \tau) \equiv \int \frac{d^D k}{(2\pi)^D} \left(e^{i\mathbf{k}(\hat{\mathbf{x}} - \mathbf{x}' - i\hat{\mathbf{p}}\tau/M)} - e^{i\mathbf{k}(\hat{\mathbf{x}} - \mathbf{x}')} \right) \quad (4B.44)$$

is a smearing operator. Inserting now a completeness relation of the momentum states in front of the time-ordering operator in Eq. (4B.38), we find

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle \equiv \int \frac{d^D p}{(2\pi\hbar)^D} e^{i\mathbf{p}\cdot\mathbf{x}_b/\hbar} e^{-\Delta\tau H(p, \mathbf{x}_a)\hbar} \langle \mathbf{p} | \hat{T} \exp \left\{ -\frac{1}{\hbar} \int_0^{\Delta\tau} d\tau \Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau) \right\} | \mathbf{x}_a \rangle. \quad (4B.45)$$

This formula can now be evaluated by expanding the time-ordered product in powers of $\Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau)$.

To first-order, we use the Baker-Campbell-Hausdorff formula (2.9) to re-order the exponential of the operators $\hat{\mathbf{x}}$ and $\hat{\mathbf{p}}$. This leads to the matrix element

$$\begin{aligned} \langle \mathbf{p} | S(\hat{\mathbf{p}}\tau, \hat{\mathbf{x}}, \mathbf{x}') | \mathbf{x}_a \rangle &= \int \frac{d^D k}{(2\pi)^D} \langle \mathbf{p} | \left(e^{i\mathbf{k}\hat{\mathbf{p}}\tau/M} e^{i\mathbf{k}(\hat{\mathbf{x}} - \mathbf{x}')} e^{-k^2\tau\hbar/2M} - e^{i\mathbf{k}(\hat{\mathbf{x}} - \mathbf{x}')} \right) | \mathbf{x}_a \rangle \\ &= \int \frac{d^D k}{(2\pi)^D} \left(e^{i\mathbf{k}(\mathbf{x}_a - \mathbf{x}' - i\mathbf{p}\tau/M)} e^{-k^2\tau\hbar/2M} - e^{i\mathbf{k}(\mathbf{x}_a - \mathbf{x}')} \right) e^{-i\mathbf{p}\mathbf{x}_a}. \end{aligned} \quad (4B.46)$$

It is now useful to introduce a softended δ -function of width $\tau M/\eta$:

$$\delta_\tau(\mathbf{x}) \equiv \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}\mathbf{x}} e^{-k^2\tau\hbar/2M}. \quad (4B.47)$$

It has the properties

$$\int d^D x \delta_\tau(\mathbf{x}) = 1, \quad \int d^D x x_i x_j \delta_\tau(\mathbf{x}) = \tau \frac{\hbar}{M} \delta_{ij}, \dots \quad (4B.48)$$

With the help of this we define the smeared potential

$$V_\tau(\mathbf{x}) \equiv \int d^D x' \delta_\tau(\mathbf{x} - \mathbf{x}') V(\mathbf{x}') = \frac{1}{(2\pi\tau\hbar/M)^{D/2}} \int d^D x' V(\mathbf{x} - \mathbf{x}') e^{-x'^2 M/2\tau\hbar} \quad (4B.49)$$

For small τ , this has an expansion

$$V_\tau(\mathbf{x}) \equiv V_\tau(\mathbf{x}) + \frac{\tau}{2} \frac{\hbar}{M} \nabla^2 V(\mathbf{x}) + \frac{\tau^2}{8} \left(\frac{\hbar}{M} \right)^2 \nabla^4 V(\mathbf{x}) + \dots \quad (4B.50)$$

Then we arrive at the first-order result

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \int \frac{d^D p}{(2\pi\hbar)^D} e^{i\mathbf{p}\cdot\Delta\mathbf{x}/\hbar} e^{-\Delta\tau H(p, \mathbf{x}_a)/\hbar} \left\{ 1 - \frac{1}{\hbar} \int_0^{\Delta\tau} d\tau W_{\mathbf{p}\tau} + \dots \right\}. \quad (4B.51)$$

where

$$W_{\mathbf{p}\tau} \equiv \langle \mathbf{p} | V_\tau(\hat{\mathbf{x}} - i\hat{\mathbf{p}}\tau/M) - V(\hat{\mathbf{x}}) | \mathbf{x}_a \rangle. \quad (4B.52)$$

We now change the variable of integration from \mathbf{p} to $\mathbf{p}' \equiv \mathbf{p} - iM\Delta\mathbf{x}/\tau$, and find (after omitting the prime)

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = e^{-M\Delta\mathbf{x}^2/2\Delta\tau\hbar} \int \frac{d^D p}{(2\pi\hbar)^D} e^{-\Delta\tau H(p, \mathbf{x}_a)/\hbar} \left\{ 1 - \frac{1}{\hbar} \int_0^{\Delta\tau} d\tau W_{\mathbf{p}\tau+iM\Delta\mathbf{x}} + \dots \right\}. \quad (4B.53)$$

Performing the momentum integration, we arrive at

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \frac{e^{-M\Delta\mathbf{x}^2/2\Delta\tau\hbar}}{(2\pi\Delta\tau\hbar/M)^{D/2}} e^{-\Delta\tau V(\mathbf{x}_a)/\hbar} \left\langle 1 - \frac{1}{\hbar} \int_0^{\Delta\tau} d\tau W_{\mathbf{p}\tau+iM\Delta\mathbf{x}} + \dots \right\rangle_p, \quad (4B.54)$$

where the expectation value of a function $\langle f(\mathbf{p}) \rangle_p$ denotes the Gaussian momentum average:

$$\langle f(\mathbf{p}) \rangle_p \equiv \int \frac{d^D p}{(2\pi\hbar)^D} f(\mathbf{p}) e^{-\Delta\tau p^2/2M\hbar} \Big/ \int \frac{d^D p}{(2\pi\hbar)^D} e^{-\Delta\tau p^2/2M\hbar}. \quad (4B.55)$$

Now we expand $\Delta V_\tau(\mathbf{x}_b - i\mathbf{p}\tau/M)$ in powers of \mathbf{p} :

$$\Delta V_\tau(\mathbf{x}) \approx V(\mathbf{x}_b) - V(\mathbf{x}_a) + \frac{\tau}{2} \frac{\hbar}{M} \nabla^2 V(\mathbf{x}_b) - i \frac{\tau}{M} \mathbf{p} \nabla V(\mathbf{x}_b) - \frac{\tau^2}{2!M^2} (\mathbf{p} \nabla)^2 V(\mathbf{x}_b). \quad (4B.56)$$

The momentum averages in formula (4B.63) are calculated with the help of the integral formula (4.331) which reads here

$$\begin{aligned} & \int \frac{d^D p}{(2\pi\hbar)^D} e^{-\Delta\tau p^2/2M\hbar} \{ 1, p^i p^j, p^{i_1} p^{i_2} p^{i_3} p^4, \dots, p^{i_1} p^{i_2} \dots p^{i_{2n-1}} p^{i_{2n}}, \dots \} \\ &= \frac{1}{(2\pi\Delta\tau\hbar/M)^{D/2}} \left\{ 1, \frac{M\hbar}{\Delta\tau} \delta^{ij}, \left(\frac{M\hbar}{\Delta\tau} \right)^2 \delta^{i_1 i_2 i_3 i_4}, \dots, \left(\frac{M\hbar}{\Delta\tau} \right)^n \delta^{i_1 i_2 \dots i_{2n-1} i_{2n}}, \dots \right\}, \end{aligned} \quad (4B.57)$$

with the contraction tensors (4.333). Applying these to the expression (4B.63) we obtain the low-order contributions to (4B.63)

$$\langle \mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a \rangle = \frac{e^{-M\Delta\mathbf{x}^2/2\Delta\tau\hbar}}{(2\pi\Delta\tau\hbar/M)^{D/2}} e^{-\Delta\tau V(\mathbf{x}_a)/\hbar} (1 + A_1 + A_2 + \dots), \quad (4B.58)$$

where

$$A_1 = -\frac{1}{\hbar} \int_0^{\Delta\tau} d\tau \left[V(\mathbf{x}_b) - V(\mathbf{x}_a) + \left(\frac{\tau}{2} - \frac{\tau^2}{2\Delta\tau} \right) \frac{\hbar}{M} \nabla^2 V(\mathbf{x}_b) + \dots \right]. \quad (4B.59)$$

After integrating over τ we recover (4B.16).

To second order, the calculation becomes more complicated since we have to find the matrix element

$$\begin{aligned} & \langle \mathbf{p} | S(\hat{\mathbf{p}}\tau, \hat{\mathbf{x}}, \mathbf{x}') S(\hat{\mathbf{p}}\tau', \hat{\mathbf{x}}, \mathbf{x}'') | \mathbf{x}_a \rangle = \int \frac{d^D k}{(2\pi)^D} \int \frac{d^D k'}{(2\pi)^D} \\ & \times \langle \mathbf{p} | \left(e^{i\mathbf{k}\hat{\mathbf{p}}\tau/M} e^{i\mathbf{k}(\hat{\mathbf{x}}-\mathbf{x}')} e^{-k^2\tau\hbar/2M} - e^{i\mathbf{k}(\hat{\mathbf{x}}-\mathbf{x}')} \right) \left(e^{i\mathbf{k}'\hat{\mathbf{p}}\tau'/M} e^{i\mathbf{k}'(\hat{\mathbf{x}}-\mathbf{x}'')} e^{-k'^2\tau'\hbar/2M} - e^{i\mathbf{k}'(\hat{\mathbf{x}}-\mathbf{x}'')} \right) | \mathbf{x}_a \rangle. \end{aligned} \quad (4B.60)$$

The first term in the product need re-ordering according to the Baker-Campbell-Hausdorff formula (2.9) which states that $e^{\hat{A}}e^{\hat{B}} = e^{\hat{B}}e^{\hat{A}}e^{[\hat{A},\hat{B}]}$, so that

$$\begin{aligned} & \langle \mathbf{p} | e^{k\hat{\mathbf{p}}\tau/M} e^{ik(\hat{\mathbf{x}}-\mathbf{x}')} e^{-k^2\tau\hbar/2M} e^{k'\hat{\mathbf{p}}\tau'/M} e^{ik'(\hat{\mathbf{x}}-\mathbf{x}'')} e^{-k'^2\tau'\hbar/2M} | \mathbf{x}_a \rangle \\ & = e^{-kk'\tau'\hbar/M} \langle \mathbf{p} | e^{k\mathbf{p}\tau/M} e^{ik(\mathbf{x}_a-\mathbf{x}'')} e^{-k^2\tau\hbar/2M} e^{k'\mathbf{p}\tau'/M} e^{ik'(\mathbf{x}_a-\mathbf{x}')} e^{-k'^2\tau'\hbar/2M} | \mathbf{x}_a \rangle. \end{aligned} \quad (4B.61)$$

The prefactor can obviously be rewritten as a differential operator:

$$e^{-kk'\tau'\hbar/M} = e^{(\tau'\hbar/M)\nabla'\nabla''}. \quad (4B.62)$$

Apart from that, the integrand consists of the product of the smeared potentials $V_\tau(\mathbf{x}' - i\mathbf{p}\tau/M)$. Thus the second-order correction in (4B.59) becomes

$$A_2 = \left\langle \frac{1}{\hbar^2} \int_0^{\Delta\tau} d\tau \int_0^\tau d\tau' W^{(2)}(\mathbf{p}) \right\rangle_p, \quad (4B.63)$$

where

$$\begin{aligned} W^{(2)}(\mathbf{p}) \equiv & \left(e^{(\tau'\hbar/M)\nabla'\nabla''} - 1 \right) V_\tau(\mathbf{x}' - i\mathbf{p}\tau/M) V_{\tau'}(\mathbf{x}'' - i\mathbf{p}\tau'/M) \Big|_{\mathbf{x}'=\mathbf{x}_a, \mathbf{x}''=\mathbf{x}_a} \\ & + [V_\tau(\mathbf{x}_b - i\mathbf{p}\tau/M) - V(\mathbf{x}_a)] [V_{\tau'}(\mathbf{x}_b - i\mathbf{p}\tau'/M) - V(\mathbf{x}_a)]. \end{aligned} \quad (4B.64)$$

By evaluating this expression we can extend the expansion (4B.16) to higher orders in $\beta = \Delta\tau/\hbar$.

The expression (4B.63) can be used to derive a compact formula for the gradient expansion of the trace log of the Hamiltonian operator $\hat{H} = \hat{\mathbf{p}}^2/2M + V(\hat{\mathbf{x}})$. We insert (4B.40) into formula and (4.290), and obtain the Euclidean-time formula

$$\text{Tr} \log \hat{H} = - \int d^D x \int_0^\infty \frac{d\tau}{\tau} \langle \mathbf{x} | e^{-\tau H(\hat{\mathbf{p}}, \mathbf{x}_a)/\hbar} \hat{T} \exp \left\{ -\frac{1}{\hbar} \int_0^\tau d\tau' \Delta V(\hat{\mathbf{x}}, \hat{\mathbf{p}}, \tau') \right\} | \mathbf{x} \rangle. \quad (4B.65)$$

Appendix 4C Potential of Thomas Fermi Model

Let us expand $f(\xi) = 1 + \sum_{n=2}^\infty a_n \xi^{n/2}$, and insert this into the self-consistent Thomas-Fermi equation (4.384) to obtain

$$\sum_{k=3}^\infty a_k \frac{k(k-2)}{4} \xi^{(k-4)/2} = \xi^{-1/2} \exp \left[\frac{3}{2} \log(1 + \sum_{k=2}^\infty a_n \xi^{n/2}) \right]. \quad (4C.1)$$

This leads to a recursive determination of the coefficients:

$$\begin{aligned} a_3 &= \frac{4}{3}, \quad a_4 = 0, \quad a_5 = \frac{2}{5}a_2, \quad a_6 = \frac{1}{3}, \quad a_7 = \frac{3}{70}a_2^2, \quad a_8 = \frac{2}{15}a_2, \\ a_9 &= \frac{2}{27} - \frac{1}{252}a_2^3, \quad a_{10} = \frac{1}{175}a_2^2, \quad a_{11} = \frac{31}{1485}a_2 + \frac{1}{1056}a_2^4, \quad \dots \end{aligned} \quad (4C.2)$$

Inserting the slope parameter $a_2 = -s$ from Eq. (4.386), we obtain a so-called asymptotic expansion of the function $f(\xi)$. This can, however, be used to obtain the plot in Fig. 4.2 only for very small ξ , due its divergence. Only after developing the resummation technique called variational perturbation theory in Chapter 5 will we able to obtain the entire plot from the expansion.

For large ξ , the behavior of $f(\xi)$ is $f(\xi) \rightarrow f_{\text{as}}(\xi) \equiv 144/\xi^3$ as verified by direct insertion into Eq. (4.384) [recall Eq. (4.387)]. The next correction to this is

$$f(\xi) = f_{\text{as}}(\xi) (1 + b_1 x^{-q} + b_2 x^{-2q} + \dots), \quad (4C.3)$$

where

$$q = \frac{1}{2} (\sqrt{73} - 7), \quad b_2 = -\frac{9b_1^2}{2(7\sqrt{73} - 67)}. \quad (4C.4)$$

with $b_1 \approx -13.3$. Fixing this parameter is equivalent to fixing the slope parameter s in the small- ξ expansion.

Variational Perturbation Theory

Most path integrals cannot be performed exactly. It is therefore necessary to develop approximation procedures which allow us to approach the exact result with any desired accuracy, at least in principle. The perturbation expansion of Chapter 3 does not serve this purpose since it diverges for any coupling strength. Similar divergencies appear in the semiclassical expansion of Chapter 4.

The present chapter develops a convergent approximation procedure to calculate Euclidean path integrals at a finite temperature. The basis for this procedure is a variational approach due to Feynman and Kleinert, which was recently extended to a systematic and uniformly convergent *variational perturbation expansion* [1].

5.1 Variational Approach to Effective Classical Partition Function

Starting point for the variational approach will be the path integral representation (3.816) for the effective classical potential introduced in Section 3.25. Explicitly, the effective classical Boltzmann factor $B(x_0)$ for a quantum system with an action

$$\mathcal{A}_e = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{x}^2(\tau) + V(x(\tau)) \right] \quad (5.1)$$

has the path integral representation [recall (3.816) and (3.809)]

$$\begin{aligned}
 B(x_0) &\equiv e^{-V^{\text{eff cl}}(x_0)/k_B T} = \oint \mathcal{D}'x e^{-\mathcal{A}_e/\hbar} = \prod_{m=1}^{\infty} \left[\int \frac{dx_m^{\text{re}} dx_m^{\text{im}}}{\pi k_B T / M \omega_m^2} \right] \times \\
 &\times \exp \left[-\frac{M}{k_B T} \sum_{m=1}^{\infty} \omega_m^2 |x_m|^2 - \frac{1}{\hbar} \int_0^{\hbar/k_B T} d\tau V \left(x_0 + \sum_{m=1}^{\infty} (x_m e^{-i\omega_m \tau} + \text{c.c.}) \right) \right], \quad (5.2)
 \end{aligned}$$

with the notation $x_m^{\text{re}} = \text{Re } x_m$, $x_m^{\text{im}} = \text{Im } x_m$. To make room for later subscripts, we shall in this chapter write \mathcal{A} instead of \mathcal{A}_e . In Section 3.25 we have derived a perturbation expansion for $B(x_0) = e^{-\beta V^{\text{eff cl}}(x_0)}$. Here we shall find a simple but quite accurate approximation for $B(x_0)$ whose effective classical potential $V^{\text{eff cl}}(x_0)$ approaches the exact expression always from above.

5.2 Local Harmonic Trial Partition Function

The desired approximation is obtained by comparing the path integral in question with a solvable trial path integral. The trial path integral consists of a suitable superposition of local harmonic oscillator path integrals centered at arbitrary average positions x_0 , each with an own frequency $\Omega^2(x_0)$. The coefficients of the superposition and the frequencies are chosen in such a way that the effective classical potential of the trial system is an optimal upper bound to the true effective classical potential. In systems with a smooth or at least not too singular potential, the accuracy of the approximation will be very good. In Section 5.13 we show how to use this approximation as a starting point of a systematic variational perturbation expansion which permits improving the result to any desired accuracy.

As a local trial action we shall take the harmonic action (3.850), which may also be considered as the action of a harmonic oscillator centered around some point x_0 :

$$\mathcal{A}_\Omega^{x_0} = \int_0^{\hbar/k_B T} d\tau M \left[\frac{\dot{x}^2}{2} + \Omega^2(x_0) \frac{(x - x_0)^2}{2} \right]. \quad (5.3)$$

However, instead of using the specific frequency $\Omega^2(x_0) \equiv V''(x_0)/M$ in (3.850), we shall choose $\Omega(x_0)$ to be an as yet unknown local trial frequency. The effective classical Boltzmann factor $B(x_0)$ associated with this trial action can be taken directly from (3.823). We simply replace the harmonic potential $M\omega^2 x^2/2$ in the defining expression (3.816) by the local trial potential $\Omega(x_0)(x - x_0)^2/2$. Then the first term in the fluctuation expansion (3.817) of the action vanishes, and we obtain, instead of (3.823), the local Boltzmann factor

$$B_\Omega(x_0) \equiv e^{-V^{\text{eff cl}}(x_0)/k_B T} = \frac{\hbar\Omega(x_0)/2k_B T}{\sinh[\hbar\Omega(x_0)/2k_B T]} \equiv Z_\Omega^{x_0}. \quad (5.4)$$

The exponential $\exp(-\beta M\omega^2 x_0^2/2)$ in (3.823) is absent since the local trial potential vanishes at $x = x_0$. The local Boltzmann factor $B_\Omega(x_0)$ is a local partition function of paths whose temporal average is restricted to x_0 , and this fact will be emphasized by the alternative notation $Z_\Omega^{x_0}$ which we shall now find convenient to use. The effective classical potential of the harmonic oscillators may also be viewed as a local free energy associated with the local partition function $Z_\Omega^{x_0}$ which we defined as

$$F_\Omega^{x_0} \equiv -k_B T \log Z_\Omega^{x_0}, \quad (5.5)$$

such that we may identify

$$V_\Omega^{\text{eff cl}}(x_0) = F_\Omega^{x_0} = k_B T \log \left\{ \frac{\sinh[\hbar\Omega(x_0)/2k_B T]}{\hbar\Omega(x_0)/2k_B T} \right\}. \quad (5.6)$$

The harmonic path integral associated with the local partition function $Z_\Omega^{x_0}$ is

$$\begin{aligned} Z_\Omega^{x_0} &= \int \mathcal{D}x(\tau) \tilde{\delta}(\bar{x} - x_0) e^{-\mathcal{A}_\Omega^{x_0}/\hbar} \\ &= \prod_{m=1}^{\infty} \left[\int \frac{dx_m^{\text{re}} dx_m^{\text{im}}}{\pi k_B T / M \omega_m^2} \right] e^{-\frac{M}{k_B T} \sum_{m=1}^{\infty} [\omega_m^2 + \Omega^2(x_0)] |x_m|^2}, \end{aligned} \quad (5.7)$$

where $\tilde{\delta}(\bar{x} - x_0)$ is the slightly modified δ -function introduced in Eq. (3.815).

We now define the *local expectation values* of an arbitrary functional $F[x(\tau)]$ within the harmonic path integral (5.7):

$$\langle F[x(\tau)] \rangle_{\Omega}^{x_0} \equiv [Z_{\Omega}^{x_0}]^{-1} \int \mathcal{D}x \tilde{\delta}(\bar{x} - x_0) e^{-\mathcal{A}_{\Omega}^{x_0}/\hbar} F[x(\tau)]. \quad (5.8)$$

The effective classical potential can then be re-expressed as a path integral

$$\begin{aligned} e^{-V^{\text{eff cl}}(x_0)/k_B T} &= Z^{x_0} = \int \mathcal{D}x \tilde{\delta}(\bar{x} - x_0) e^{-\mathcal{A}/\hbar} \\ &\equiv \int \mathcal{D}x \tilde{\delta}(\bar{x} - x_0) e^{-\mathcal{A}_{\Omega}^{x_0}/\hbar} e^{-(\mathcal{A} - \mathcal{A}_{\Omega}^{x_0})/\hbar} \\ &= Z_{\Omega}^{x_0} \langle e^{-(\mathcal{A} - \mathcal{A}_{\Omega}^{x_0})/\hbar} \rangle_{\Omega}^{x_0}. \end{aligned} \quad (5.9)$$

We now take advantage of the fact that the expectation value on the right-hand side possesses an easily calculable bound given by the *Jensen-Peierls inequality*:

$$\langle e^{-(\mathcal{A} - \mathcal{A}_{\Omega}^{x_0})/\hbar} \rangle_{\Omega}^{x_0} \geq e^{-\langle \mathcal{A}/\hbar - \mathcal{A}_{\Omega}^{x_0}/\hbar \rangle_{\Omega}^{x_0}}. \quad (5.10)$$

This implies that the effective classical potential has an upper bound

$$V^{\text{eff cl}}(x_0) \leq F_{\Omega}^{x_0}(x_0) + k_B T \langle \mathcal{A}/\hbar - \mathcal{A}_{\Omega}^{x_0}/\hbar \rangle_{\Omega}^{x_0}. \quad (5.11)$$

The Jensen-Peierls inequality is a consequence of the *convexity* of the exponential function: The average of two exponentials is always larger than the exponential at the average point (see Fig. 5.1):

$$\frac{e^{-x_1} + e^{-x_2}}{2} \geq e^{-\frac{x_1 + x_2}{2}}. \quad (5.12)$$

This convexity property of the exponential function can be generalized to an exponential functional. Let $\mathcal{O}[x]$ be an arbitrary functional in the space of paths $x(\tau)$, and

$$\langle \mathcal{O}[x] \rangle \equiv \int \mathcal{D}\mu[x] \mathcal{O}[x] \quad (5.13)$$

Figure 5.1 Illustration of convexity of exponential function e^{-x} , satisfying $\langle e^{-x} \rangle \geq e^{-\langle x \rangle}$ everywhere.

an expectation value in this space. The measure of integration $\mu[x]$ is supposed to be normalized so that $\langle 1 \rangle = 1$. Then (5.12) generalizes to

$$\langle e^{-\mathcal{O}} \rangle \geq e^{-\langle \mathcal{O} \rangle}. \tag{5.14}$$

To prove this we first observe that the inequality (5.12) remains valid if x_1, x_2 are replaced by the values of an arbitrary function $\mathcal{O}(x)$:

$$\frac{e^{-\mathcal{O}(x_1)} + e^{-\mathcal{O}(x_2)}}{2} \geq e^{-\frac{\mathcal{O}(x_1) + \mathcal{O}(x_2)}{2}}. \tag{5.15}$$

This inequality is then generalized with the help of any positive measure $\mu(x)$, with unit normalization, $\int d\mu(x) = 1$, to

$$\int d\mu(x) e^{-\mathcal{O}(x)} \geq e^{\int d\mu(x) e^{-\mathcal{O}(x)}}, \tag{5.16}$$

and further to

$$\int \mathcal{D}\mu[x] e^{-\mathcal{O}[x]} \geq e^{\int \mathcal{D}\mu[x] e^{-\mathcal{O}[x]}}, \tag{5.17}$$

where $\mu[x]$ is any positive functional measure with the normalization $\int \mathcal{D}\mu[x] = 1$. This shows that Eq. (5.14) is true, and hence also the Jensen-Peierls inequality (5.10).

Since the kinetic energies in the two actions \mathcal{A} and $\mathcal{A}_\Omega^{x_0}$ in (5.11) are equal, the inequality (5.11) can also be written as

$$V^{\text{eff cl}}(x_0) \leq F_\Omega^{x_0} + \frac{k_B T}{\hbar} \int_0^{\hbar/k_B T} d\tau \left\langle \left[V(x(\tau)) - M \frac{\Omega^2(x_0)}{2} (x(\tau) - x_0)^2 \right] \right\rangle_\Omega^{x_0}. \tag{5.18}$$

The local expectation value on the right-hand side is easily calculated. Recalling the definition (3.856) we have to use the correlation functions of $\eta(\tau)$ without the zero frequency in Eq. (3.842):

$$\langle \eta(\tau) \eta(\tau') \rangle_\Omega^{x_0} \equiv a_{\tau\tau'}^2(x_0) = \frac{\hbar}{M} \left[\frac{1}{2\Omega(x_0)} \frac{\cosh \Omega(x_0)(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\Omega(x_0)\hbar\beta/2)} - \frac{1}{\hbar\beta\Omega^2} \right], \tag{5.19}$$

valid for arguments $\tau, \tau' \in [0, \hbar\beta]$. By analogy with (3.806) we may denote this quantity by $a_{\Omega(x_0)}^2(\tau, \tau')$, which we have shortened to $a_{\tau\tau'}^2(x_0)$, to avoid a pile-up of indices.

All subtracted correlation functions can be obtained from the functional derivatives of the local generating functional

$$Z_\Omega^{x_0}[j] \equiv \int \mathcal{D}x(\tau) \tilde{\delta}(\bar{x} - x_0) e^{-(1/\hbar) \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \{ \dot{x}^2(\tau) + \Omega^2(x_0)[x(\tau) - x_0]^2 \} - j(\tau)[x(\tau) - x_0] \right]}, \tag{5.20}$$

whose explicit form was calculated in (3.847):

$$Z_\Omega^{x_0}[j] = Z_\Omega^{x_0} \exp \left\{ \frac{1}{2M\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\Omega^2(x_0), e}^{\text{p}'}(\tau - \tau') j(\tau') \right\}. \tag{5.21}$$

If desired, the Green function can be continued analytically to the real-time retarded Green function

$$G_{\Omega^2}^R(t, t') = \frac{M}{\hbar} \Theta(t - t') \langle x(t)x(t') \rangle \quad (5.22)$$

in a way to be explained later in Section 18.2.

With the help of the spectral decomposition of these correlation functions to be derived in Section 18.2, it is possible to show that the lowest frequency content of the zero-temperature Green function (5.22) contains the information on the lowest excitation energy of a physical system. For the frequency ω of an oscillator Green function this is trivially true. It is then obvious that in the above approximation where the Green function is a superposition of oscillator Green functions of frequencies $\Omega(x_0)$, the minimal zero-temperature value of $\hbar\Omega(x_0)$ gives an approximation to the energy difference between ground and first excited states. In Table 5.1 we see that for the anharmonic oscillator, this approximation is quite good.

As shown in Fig. 3.14, the *local fluctuation square width*

$$\langle \eta^2(\tau) \rangle_{\Omega}^{x_0} = \langle (x(\tau) - x_0)^2 \rangle_{\Omega}^{x_0} = a_{\tau\tau}^2(x_0) \equiv a_{\Omega(x_0)}^2, \quad (5.23)$$

with the explicit form (3.806),

$$a_{\Omega(x_0)}^2 = \frac{2}{M\beta} \sum_{m=1}^{\infty} \frac{1}{\omega_m^2 + \Omega^2(x_0)} = \frac{1}{M\beta\Omega^2(x_0)} \left[\frac{\hbar\beta\Omega(x_0)}{2} \coth \frac{\hbar\beta\Omega(x_0)}{2} - 1 \right], \quad (5.24)$$

goes to zero for high temperature like

$$a_{\Omega(x_0)}^2 \xrightarrow{T \rightarrow \infty} \hbar^2 / 12Mk_B T. \quad (5.25)$$

This is in contrast to the unrestricted expectation $\langle (x(\tau) - x_0)^2 \rangle_{\Omega(x_0)}$ of the harmonic oscillator which includes the $\omega_m = 0$ -term in the spectral decomposition (3.803):

$$a_{\text{tot}}^2 \equiv \langle (x(\tau) - x_0)^2 \rangle_{\Omega(x_0)} = a_{\Omega(x_0)}^2 + \frac{k_B T}{M\Omega^2(x_0)}. \quad (5.26)$$

This grows linearly with T following the equipartition theorem (3.803).

As discussed in Section 3.25, this difference is essential for the reliability of a perturbation expansion of the effective classical potential. It will also be essential for the quality of the variational approach in this chapter.

The local fluctuation square width $a_{\Omega(x_0)}^2$ measures the importance of quantum fluctuations at nonzero temperatures. These decrease with increasing temperatures. In contrast, the square width of the $\omega_0 = 0$ -term grows with the temperature showing the growing importance of classical fluctuations.

This behavior of the fluctuation width is in accordance with our previous observation after Eq. (3.840) on the finite width of the Boltzmann factor $B(x_0) = e^{-V^{\text{eff cl}}(x_0)/k_B T}$ for low temperatures in comparison to the diverging width of the

alternative Boltzmann factor (3.841) formed from the partition function density $\tilde{B}(x_0) \equiv l_e(\hbar\beta) z(x) = e^{-\tilde{V}^{\text{eff cl}}(x_0)/k_B T}$.

Since $a_{\Omega(x_0)}^2$ is finite at *all* temperatures, the quantum fluctuations can be treated approximately. The approximation improves with growing temperatures where $a_{\Omega(x_0)}^2$ tends to zero. The thermal fluctuations, on the other hand, diverge at high temperatures. Their evaluation requires a numeric integration over x_0 in the final effective classical partition function (3.811).

Having determined $a_{\Omega(x_0)}^2$, the calculation of the local expectation value $\langle V(x(\tau)) \rangle_{\Omega}^{x_0}$ is quite easy following the steps in Subsection 3.25.8. The result is the smearing formula analogous to (3.875): We write $V(x(\tau))$ as a Fourier integral

$$V(x(\tau)) = \int_{-\infty}^{\infty} \frac{dk}{2\pi} e^{ikx(\tau)} \tilde{V}(k), \quad (5.27)$$

and obtain with the help of Wick's rule (3.307) the expectation value

$$\langle V(x(\tau)) \rangle_{\Omega}^{x_0} = V_{a^2}(x_0) \equiv \int_{-\infty}^{\infty} \frac{dk}{2\pi} \tilde{V}(k) e^{ikx_0 - a^2(x_0)k^2/2}. \quad (5.28)$$

For brevity, we have used the shorter notation $a^2(x_0)$ for $a_{\Omega(x_0)}^2$, and shall do so in the remainder of this chapter. Reinsert the Fourier coefficients of the potential

$$\tilde{V}(k) = \int_{-\infty}^{\infty} dx V(x) e^{-ikx}, \quad (5.29)$$

we may perform the integral over k and obtain the convolution integral

$$\langle V(x(\tau)) \rangle_{\Omega}^{x_0} = V_{a^2}(x_0) \equiv \int_{-\infty}^{\infty} \frac{dx'_0}{\sqrt{2\pi a^2(x_0)}} e^{-(x'_0 - x_0)^2/2a^2(x_0)} V(x'_0). \quad (5.30)$$

As in (3.875), the convolution integral smears the original potential $V(x_0)$ out over a length scale $a(x_0)$, thus accounting for the effects of quantum-statistical path fluctuations.

The expectation value $\langle (x(\tau) - x_0)^2 \rangle_{\Omega}^{x_0}$ in Eq. (5.26) is, of course, a special case of this general *smearing rule*:

$$(x - x_0)_{a^2}^2 = \int_{-\infty}^{\infty} \frac{dx'}{\sqrt{2\pi a^2}} e^{-(1/2a^2)(x' - x_0)^2} (x' - x_0)^2 = a^2(x_0). \quad (5.31)$$

Hence we obtain for the effective classical potential the approximation

$$W_1^{\Omega}(x_0) \equiv F_{\Omega}^{x_0} + V_{a^2}(x_0) - \frac{M}{2} \Omega^2(x_0) a^2(x_0), \quad (5.32)$$

which by the Jensen-Peierls inequality lies always above the true result:

$$W_1^{\Omega}(x_0) \geq V^{\text{eff cl}}(x_0). \quad (5.33)$$

A minimization of $W_1^\Omega(x_0)$ in $\Omega(x_0)$ produces an optimal variational approximation to be denoted by $W_1(x_0)$.

For the harmonic potential $V(x) = M\omega^2 x^2/2$, the smearing process leads to $V_{a^2}(x_0) = M\omega^2(x_0^2 + a^2)/2$. The extremum of $W_1^\Omega(x_0)$ lies at $\Omega(x_0) \equiv \omega$, so that the optimal upper bound is

$$W_1(x_0) = F_\omega^{x_0} + M\omega^2 \frac{x_0^2}{2}. \quad (5.34)$$

Thus, for the harmonic oscillator, $W_1^\Omega(x_0)$ happens to coincide with the exact effective classical potential $V_\omega^{\text{eff cl}}(x_0)$ found in (3.830).

5.3 The Optimal Upper Bound

We now determine the frequency $\Omega(x_0)$ of the local trial oscillator which optimizes the upper bound in Eq. (5.33). The derivative of $W_1^\Omega(x_0)$ with respect to $\Omega^2(x_0)$ has two terms:

$$\frac{dW_1^\Omega(x_0)}{d\Omega^2(x_0)} = \frac{\partial W_1^\Omega(x_0)}{\partial \Omega^2(x_0)} + \frac{\partial W_1^\Omega(x_0)}{\partial a^2(x_0)} \bigg|_{\Omega(x_0)} \frac{\partial a^2(x_0)}{\partial \Omega^2(x_0)}.$$

The first term is

$$\frac{\partial W_1(x_0)}{\partial \Omega^2(x_0)} = \frac{M}{2} \left\{ \frac{k_B T}{M\Omega^2(x_0)} \left[\frac{\hbar\Omega}{2k_B T} \coth\left(\frac{\hbar\Omega}{2k_B T}\right) - 1 \right] - a^2(x_0) \right\}. \quad (5.35)$$

It vanishes automatically due to (5.24). Thus we only have to minimize $W_1^\Omega(x_0)$ with respect to $a^2(x_0)$ by satisfying the condition

$$\frac{\partial W_1^\Omega(x_0)}{\partial a^2(x_0)} = 0. \quad (5.36)$$

Inserting (5.32), this determines the trial frequency

$$\Omega^2(x_0) = \frac{2}{M} \frac{\partial V_{a^2}(x_0)}{\partial a^2(x_0)}. \quad (5.37)$$

In the Fourier integral (5.28) for $V_{a^2}(x_0)$, the derivative $2(\partial/\partial a^2)V_{a^2}$ is represented by a factor $-k^2$ which, in turn, is equivalent to $\partial/\partial x_0^2$. This leads to the alternative equation:

$$\Omega^2(x_0) = \frac{1}{M} \left[\frac{\partial^2}{\partial x_0^2} V_{a^2}(x_0) \right]_{a^2=a^2(x_0)}. \quad (5.38)$$

Note that the partial derivatives must be taken at *fixed* a^2 which is to be set equal to $a^2(x_0)$ at the end.

The potential $W_1^\Omega(x_0)$ with the extremal $\Omega^2(x_0)$ and the associated $a^2(x_0)$ of (5.24) constitutes the *Feynman-Kleinert approximation* $W_1(x_0)$ to the effective classical potential $V^{\text{eff cl}}(x_0)$.

It is worth noting that due to the vanishing of the partial derivative $\partial W_1^\Omega(x_0)/\partial \Omega^2(x_0)$ in (5.35) we may consider $\Omega^2(x_0)$ and $a^2(x_0)$ as arbitrary variational parameters in the expression (5.32) for $W_1^\Omega(x_0)$. Then the *independent* variation of $W_1^\Omega(x_0)$ with respect to these two parameters yields both (5.24) and the minimization condition (5.37) for $\Omega^2(x_0)$.

From the extremal $W_1^\Omega(x_0)$ we obtain the approximation for the partition function and the free energy [recall (3.837)]

$$Z_1 = e^{-F_1/k_B T} = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-W_1(x_0)/k_B T} \leq Z, \quad (5.39)$$

where $l_e(\hbar\beta)$ is the thermal de Broglie length defined in Eq. (2.353). We leave it to the reader to calculate the second derivative of $W_1^\Omega(x_0)$ with respect to $\Omega^2(x_0)$ and to prove that it is nonnegative, implying that the above extremal solution is a local *minimum*.

5.4 Accuracy of Variational Approximation

The accuracy of the approximate effective classical potential $W_1(x_0)$ can be estimated by the following observation: In the limit of high temperatures, the approximation is perfect by construction, due the shrinking width (5.25) of the nonzero frequency fluctuations. This makes $W_1(x_0)$ in (5.31) converge against $V(x_0)$, just as the exact effective classical potential in Eq. (3.812).

In the opposite limit of low temperatures, the integral over x_0 in the general expression (3.811) is dominated by the minimum of the effective classical potential. If its position is denoted by x_m , we have the saddle point approximation (see Section 4.2)

$$Z \xrightarrow{T \rightarrow 0} e^{-V^{\text{eff cl}}(x_m)/k_B T} \int \frac{dx_0}{l_e(\hbar\beta)} e^{-[V^{\text{eff cl}}(x_m)]''(x_0-x_m)^2/2k_B T}. \quad (5.40)$$

The exponential of the prefactor yields the leading low-temperature behavior of the free energy:

$$F \xrightarrow{T \rightarrow 0} V^{\text{eff cl}}(x_m). \quad (5.41)$$

The Gaussian integral over x_0 contributes a term

$$\Delta F = k_B T \log \left\{ \frac{\hbar}{k_B T} \sqrt{\frac{[V^{\text{eff cl}}(x_m)]''}{M}} \right\}, \quad (5.42)$$

which accounts for the entropy of x_0 fluctuations around x_m [recall Eq. (1.568)]. Moreover, at zero temperature, the free energy F converges against the ground state energy $E^{(0)}$ of the system, so that

$$E^{(0)} = V^{\text{eff cl}}(x_m). \quad (5.43)$$

The minimum of the approximate effective classical potential, $W_1^\Omega(x_0)$ with respect to $\Omega(x_0)$ supplies us with a variational approximation to the free energy F_1 , which in the limit $T \rightarrow 0$ yields a variational approximation to the ground state energy

$$E_1^{(0)} = F_1|_{T=0} \equiv W_1(x_m)|_{T=0}. \quad (5.44)$$

By taking the $T \rightarrow 0$ limit in (5.32) we see that

$$\lim_{T \rightarrow 0} W_1^\Omega(x_0) = \frac{1}{2} [\hbar\Omega(x_0) - M\Omega^2(x_0)a^2(x_0)] + V_{a^2}(x_0). \quad (5.45)$$

In the same limit, Eq. (5.24) gives

$$\lim_{T \rightarrow 0} a^2(x_0) = \frac{\hbar}{2M\Omega(x_0)}, \quad (5.46)$$

so that

$$\lim_{T \rightarrow 0} W_1^\Omega(x_0) = \frac{1}{4}\hbar\Omega(x_0) + V_{a^2}(x_0) = \frac{1}{8} \frac{\hbar^2}{Ma^2(x_0)} + V_{a^2}(x_0). \quad (5.47)$$

The right-hand side is recognized as the expectation value of the Hamiltonian operator

$$\hat{H} = \frac{\hat{p}^2}{2M} + V(x) \quad (5.48)$$

in a normalized Gaussian wave packet of width a centered at x_0 :

$$\psi(x) = \frac{1}{(2\pi a^2)^{1/4}} \exp\left[-\frac{1}{4a^2}(x-x_0)^2\right]. \quad (5.49)$$

Indeed,

$$\langle \hat{H} \rangle_\psi \equiv \int_{-\infty}^{\infty} dx \psi^*(x) \hat{H} \psi(x) = \frac{1}{8} \frac{\hbar^2}{Ma^2} + V_{a^2}(x_0). \quad (5.50)$$

Let E_1 be the minimum of this expectation under the variation of x_0 and a^2 :

$$E_1 = \min_{x_0, a^2} \langle \hat{H} \rangle_\psi. \quad (5.51)$$

This is the variational approximation to the ground state energy provided by the *Rayleigh-Ritz method*.

In the low temperature limit, the approximation F_1 to the free energy converges toward E_1 :

$$\lim_{T \rightarrow 0} F_1 = E_1. \quad (5.52)$$

The approximate effective classical potential $W_1(x_0)$ is for all temperatures and x_0 more accurate than the estimate of the ground state energy E_0 by the minimal expectation value (5.51) of the Hamiltonian operator in a Gaussian wave packet. For potentials with a pronounced unique minimum of quadratic shape, this estimate is known to be excellent.

Table 5.1 Comparison of variational energy $E_1 = \lim_{T \rightarrow 0} F_1$, obtained from Gaussian trial wave function, with exact ground state energy $E_{\text{ex}}^{(0)}$. The energies of the first two excited states $E_{\text{ex}}^{(1)}$ and $E_{\text{ex}}^{(2)}$ are listed as well. The level splitting $\Delta E_{\text{ex}}^{(0)} = E_{\text{ex}}^{(1)} - E_{\text{ex}}^{(0)}$ to the first excited state is shown in column 6. We see that it is well approximated by the value of $\Omega(0)$, as it should (see the discussion after Eq. (5.21)).

In Table 5.1 we list the energies $E_1 = W_1(0)$ for a particle in an anharmonic oscillator potential. Its action will be specified in Section 5.7, where the approximation $W_1(x_0)$ will be calculated and discussed in detail. The table shows that this approximation promises to be quite good [2].

With the effective classical potential having good high- and low-temperature limits, it is no surprise that the approximation is quite reliable at all temperatures.

Even if the potential minimum is not smooth, the low-temperature limit can be of acceptable accuracy. An example is the three-dimensional Coulomb system for which the limit (5.51) becomes (with the obvious optimal choice $x_0 = 0$)

$$E_1 = \min_a \left(\frac{3}{8} \frac{\hbar^2}{Ma^2} - \frac{2}{\sqrt{\pi}} \frac{e^2}{\sqrt{2a^2}} \right) = -\frac{3}{8} \frac{\hbar^2}{Ma_{\min}^2}. \quad (5.53)$$

The minimal value of a is $a_{\min} = \sqrt{9\pi/32}a_H$ where $a_H = \hbar^2/Me^2$ is the Bohr radius (4.376) of the hydrogen atom. In terms of it, the minimal energy has the value $E_1 = -(4/3\pi)e^2/a_H$. This is only 15% percent different from the true ground state energy of the Coulomb system $E_{\text{ex}}^{(0)} = -(1/2)e^2/a_H$. Such a high degree of accuracy may seem somewhat surprising since the exact Coulomb wave function $\psi(\mathbf{x}) = (\pi a_H^3)^{-1/2} \exp(-r/a_H)$ is far from being a Gaussian.

The partition function of the Coulomb system can be calculated only after subtracting the free-particle partition function and screening the $1/r$ -behavior down to a finite range. The effective classical free energy F_1 of the Coulomb potential

obtained by this method is, at any temperature, more accurate than the difference between E_1 and $E_{\text{ex}}^{(0)}$. More details will be given in Section 5.10.

5.5 Weakly Bound Ground State Energy in Finite-Range Potential Well

The variational approach allows us to derive a simple approximation for the bound-state energy in an arbitrarily shaped potential of finite range, for which the binding energy is very weak. Precisely speaking, the falloff of the ground state wave function has to lie outside the range of the potential. A typical example for this situation is the binding of electrons to Cooper pairs in a superconductor. The attractive force comes from the electron-phonon interaction which is weakened by the Coulomb repulsion. The potential has a complicated shape, but the binding energy is so weak that the wave function of a Cooper pair reaches out to several thousand lattice spacings, which is much larger than the range of the potential, which extends only over maximally a hundred lattice spacings. In this case one may practically replace the potential by an equivalent δ -function potential.

The present considerations apply to this situation. Let us assume the absolute minimum of the potential to lie at the origin. The first-order variational energy at the origin is given by

$$W_1(0) = \frac{\Omega}{2} + V_{a^2}(0), \quad (5.54)$$

where by (5.30)

$$V_{a^2}(0) = \int_{-\infty}^{\infty} \frac{dx'_0}{\sqrt{2\pi a^2}} e^{-x_0'^2/2a^2} V(x'_0). \quad (5.55)$$

By assumption, the binding energy is so small that the ground state wave function does not fall off within the range of $V(x_0)$. Hence we can approximate

$$V_{a^2}(0) \approx \sqrt{\frac{\Omega}{\pi}} \int_{-\infty}^{\infty} dx'_0 V(x'_0), \quad (5.56)$$

where we have inserted $a^2 = 1/2\Omega$. Extremizing this in Ω yields the approximate ground state energy

$$E_1^{(0)} \approx -\frac{1}{2\pi} \left[-\int_{-\infty}^{\infty} dx'_0 V(x'_0) \right]^2. \quad (5.57)$$

By applying this result to a simple δ -function potential at the origin,

$$V(x) = -g\delta(x), \quad g > 0, \quad (5.58)$$

we find an approximate ground state energy

$$E_1^{(0)} = -\frac{1}{2\pi} g^2. \quad (5.59)$$

The exact value is

$$E^{(0)} = -\frac{1}{2} g^2. \quad (5.60)$$

The failure of the variational approximation is due to the fact that outside the range of the potential, the wave function is a simple exponential $e^{-k|x|}$ with $k = \sqrt{-2E^{(0)}}$, and not a Gaussian. In fact, if we consider the expectation value of the Hamiltonian operator

$$H = -\frac{1}{2} \frac{d^2}{dx^2} - g\delta(x) \quad (5.61)$$

for a normalized trial wave function

$$\psi(x) = \sqrt{K} e^{-K|x|}, \quad (5.62)$$

we obtain a variational energy

$$W_1 = \frac{K^2}{2} - gK, \quad (5.63)$$

whose minimum gives the exact ground state energy (5.60). Thus, problems of the present type call for the development of a variational perturbation theory for which Eq. (5.54) and (5.55) read

$$W(0) = \frac{K^2}{2} + V_K(0), \quad (5.64)$$

where

$$V_K(0) = K \int_{-\infty}^{\infty} \frac{dx'_0}{a} e^{-K|x_0|} V(x_0). \quad (5.65)$$

For an arbitrary attractive potential whose range is much shorter than a , this leads to the correct energy for a weakly bound ground state

$$E_1^{(0)} \approx -\frac{1}{2} \left[-\int_{-\infty}^{\infty} dx'_0 V(x_0) \right]^2. \quad (5.66)$$

5.6 Possible Direct Generalizations

Let us remark that there is a possible immediate generalization of the above variational procedure. One may treat higher components x_m with $m > 0$ accurately, say up to $m = \bar{m} - 1$, where \bar{m} is some integer > 1 , using the ansatz

$$\begin{aligned} Z_{\bar{m}} &\equiv \int \mathcal{D}x(\tau) \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar/k_B T} \frac{M}{2} \left[\dot{x}^2(\tau) + \Omega^2(x_0, \dots, x_{\bar{m}}) \right. \right. \\ &\quad \left. \left. \times \left(x(\tau) - x_0 - \sum_{m=1}^{\bar{m}-1} (x_m e^{-i\omega_m \tau} + \text{c.c.}) \right)^2 \right] \right\} e^{-(1/k_B T) L_{\bar{m}}(x_0, \dots, x_{\bar{m}})} \\ &= \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \prod_{n=1}^{\bar{m}-1} \left[\int \frac{dx_m^{\text{re}} dx_m^{\text{im}}}{\pi k_B T / M \omega_m^2} \frac{\omega_m^2 + \Omega^2(x_0)}{\omega_m^2} \right] \\ &\quad \times \frac{\hbar\Omega(x_0)/2k_B T}{\sinh(\hbar\Omega(x_0)/2k_B T)} e^{-L_{\bar{m}}(x_0, \dots, x_{\bar{m}})/k_B T}, \end{aligned} \quad (5.67)$$

with the trial function $L_{\bar{m}}$:

$$L_{\bar{m}}(x_0, \dots, x_{\bar{m}}) = \frac{k_B T}{\hbar} \int_0^{\hbar/k_B T} d\tau V_{a_{\bar{m}}}^2 \left(x_0 + \sum_{m=1}^{\bar{m}-1} (x_m e^{-i\omega_m \tau} + \text{c.c.}) \right) - \frac{M}{2} \Omega^2(x_0, \dots, x_{\bar{m}}) a_{\bar{m}}^2, \quad (5.68)$$

and a smearing square width of the potential

$$\begin{aligned} a_{\bar{m}}^2 &= \frac{2k_B T}{M} \sum_{m=\bar{m}}^{\infty} \frac{1}{\omega_m^2 + \Omega^2} \\ &= \frac{k_B T}{M\Omega^2} \left(\frac{\hbar\Omega}{2k_B T} \coth \frac{\hbar\Omega}{2k_B T} - 1 \right) - \frac{2k_B T}{M} \sum_{m=1}^{\bar{m}-1} \frac{1}{\omega_m^2 + \Omega^2}. \end{aligned} \quad (5.69)$$

For the partition function alone the additional work turns out to be not very rewarding since it renders only small improvements. It turns out that in the low-temperature limit $T \rightarrow 0$, the free energy is still equal to the optimal expectation of the Hamiltonian operator in the Gaussian wave packet (5.49).

Note that the ansatz (5.7) [as well as (5.67)] cannot be improved by allowing the trial frequency $\Omega(x_0)$ to be a matrix $\Omega_{mm'}(x_0)$ in the space of Fourier components x_m [i.e., by using $\sum_{m,m'} \Omega_{mm'}(x_0) x_m^* x_{m'}$ instead of $\Omega(x_0) \sum_m |x_m|^2$]. This would also lead to an exactly integrable trial partition function. However, after going through the minimization procedure one would fall back to the diagonal solution $\Omega_{mm'}(x_0) = \delta_{mm'} \Omega(x_0)$.

5.7 Effective Classical Potential for Anharmonic Oscillator and Double-Well Potential

For a typical application of the approximation method consider the Euclidean action

$$\mathcal{A}[x] = \int_0^{\hbar/k_B T} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) + \frac{g}{4} x^4 \right]. \quad (5.70)$$

Let us write $1/k_B T$ as β and use natural units with $M = 1$, $\hbar = k_B = 1$. We have to distinguish two cases:

a) Case $\omega^2 > 0$, Anharmonic Oscillator

Setting $\omega^2 = 1$, the smeared potential (5.30) is according to formula (3.879):

$$V_{a^2}(x_0) = \frac{x_0^2}{2} + \frac{g}{4} x_0^4 + \frac{a^2}{2} + \frac{3}{2} g x_0^2 a^2 + \frac{3g}{4} a^4. \quad (5.71)$$

Differentiating this with respect to $a^2/2$ gives, via (5.37),

$$\Omega^2(x_0) = [1 + 3g x_0^2 + 3g a^2(x_0)]. \quad (5.72)$$

This equation is solved at each x_0 by iteration together with (5.24),

$$a^2(x_0) = \frac{1}{\beta\Omega^2(x_0)} \left[\frac{\beta\Omega(x_0)}{2} \coth \frac{\beta\Omega(x_0)}{2} - 1 \right]. \quad (5.73)$$

An initial approximation such as $\Omega(x_0) = 0$ is inserted into (5.73) to find $a^2(x_0) \equiv \beta/12$, which serves to calculate from (5.72) an improved $\Omega^2(x_0)$, and so on. The iteration converges rapidly. Inserting the final $a^2(x_0), \Omega^2(x_0)$ into (5.71) and (5.32),

Figure 5.2 Approximate free energy F_1 of anharmonic oscillator as compared with the exact energy F_{ex} , the classical limit $F_{\text{cl}} = -(1/\beta) \log \int_{-\infty}^{\infty} (dx/\sqrt{2\pi\beta}) e^{-\beta V(x)}$, as well as an earlier approximation $F_0 = -(1/\beta) \log Z_0$ of Feynman's corresponding to F_1 for the nonoptimal choice $\Omega = 0$, $a^2 = \beta/12$. Note that F_0, F_1 satisfy the inequality $F_{0,1} \geq F$, while F_{cl} does not.

we obtain the desired approximation $W_1(x_0)$ to the effective classical potential $V^{\text{eff cl}}(x_0)$. By performing the integral (5.39) in x_0 we find the approximate free energy F_1 plotted as a function of β in Fig. 5.2. The exact free-energy values are obtained from the known energy eigenvalues of the anharmonic oscillator. They are seen to lie closely below the approximate F_1 curve. For comparison, we have also plotted the classical approximation $F_{\text{cl}} = -(1/\beta) \log Z_{\text{cl}}$ which does not satisfy the Jensen-Peierls inequality and lies *below* the exact curve.

In his book on statistical mechanics [3], Feynman gives another approximation, called here F_0 , which can be obtained from the present $W_1(x_0)$ by ending the iteration of (5.72), (5.73) after the first step, i.e., by using the constant nonminimal variational parameters $\Omega(x_0) \equiv 0$, $a^2(x_0) \equiv \hbar^2\beta/12M$. This leads to the approximation

$$V_{a^2}(x_0) \approx V(x_0) + \frac{1}{2} \frac{\hbar^2\beta}{12M} V''(x_0) + \frac{1}{8} \left(\frac{\hbar^2\beta}{12M} \right)^2 V^{(4)}(x_0) + \dots, \quad (5.74)$$

referred to as Wigner's expansion [4]. The approximation F_0 is good only at higher temperatures, as seen in Fig. 5.2. Just like F_1 , the curve F_0 lies also above the exact curve since it is subject to the Jensen-Peierls inequality. Indeed, the inequality holds for the potential $W_1(x_0)$ in the general form (5.32), i.e., irrespective of the minimization in $a^2(x_0)$. Thus it is valid for arbitrary $\Omega^2(x_0)$, in particular for $\Omega^2(x_0) \equiv 0$.

In the limit $T \rightarrow 0$, the free energy F_1 yields the following approximation for the ground state energy $E^{(0)}$ of the anharmonic oscillator:

$$E_1^{(0)} = \frac{1}{4\Omega} + \frac{\Omega}{4} + \frac{3}{4} \frac{g}{4\Omega^2}. \quad (5.75)$$

This approximation is very good for all coupling strengths, including the strong-coupling limit. In this limit, the optimal frequency and energy have the expansions

$$\Omega_1 = \left(\frac{g}{4}\right)^{1/3} \left[6^{1/3} + \frac{1}{2^{1/3}3^{4/3}} \frac{1}{(g/4)^{2/3}} + \dots \right], \quad (5.76)$$

and

$$\begin{aligned} E_1^{(0)}(g) &\approx \left(\frac{g}{4}\right)^{1/3} \left[\left(\frac{3}{4}\right)^{4/3} + \frac{1}{2^{7/3}3^{1/3}} \frac{1}{(g/4)^{2/3}} + \dots \right] \\ &\approx \left(\frac{g}{4}\right)^{1/3} \left[0.681420 + 0.13758 \frac{1}{(g/4)^{2/3}} + \dots \right]. \end{aligned} \quad (5.77)$$

The coefficients are quite close to the precise limiting expression to be calculated in Section 5.15 (listed in Table 5.9).

b) Case $\omega^2 < 0$: The Double-Well Potential

For $\omega^2 = -1$, we slightly modify the potential by adding a constant $1/4g$, so that it becomes

$$V(x) = -\frac{x^2}{2} + \frac{g}{4}x^4 + \frac{1}{4g}. \quad (5.78)$$

The additional constant ensures a smooth behavior of the energies in the limit $g \rightarrow 0$. Since the potential possesses now two symmetric minima, it is called the *double-well potential*. Its smeared version $V_{a^2}(x_0)$ can be taken from (5.71), after a sign change in the first and third terms (and after adding the constant $1/4g$).

Now the trial frequency

$$\Omega^2(x_0) = -1 + 3gx_0^2 + 3ga^2(x_0) \quad (5.79)$$

can become negative, although it turns out to remain always larger than $-4\pi^2/\beta^2$, since the solution is incapable of crossing the first singularity in the sum (5.24)

from the right. Hence the smearing square width $a^2(x_0)$ is always positive. For $\Omega^2 \in (-4\pi^2/\beta^2, 0)$, the sum (5.24) gives

$$\begin{aligned} a^2(x_0) &= \frac{2}{\beta} \sum_{m=1}^{\infty} \frac{1}{\omega_m^2 + \Omega^2(x_0)} \\ &= \frac{1}{\beta\Omega^2(x_0)} \left(\frac{\beta|\Omega(x_0)|}{2} \cot \frac{\beta|\Omega(x_0)|}{2} - 1 \right), \end{aligned} \quad (5.80)$$

which is the expression (5.73), continued analytically to imaginary $\Omega(x_0)$. The above procedure for finding $a^2(x_0)$ and $\Omega^2(x_0)$ by iteration of (5.79) and (5.80) is not applicable near the central peak of the double well, where it does not converge. There one finds the solution by searching for the zero of the function of $\Omega^2(x_0)$

$$f(\Omega^2(x_0)) \equiv a^2(x_0) - \frac{1}{3g}[1 + \Omega^2(x_0) - 3gx_0^2], \quad (5.81)$$

with $a^2(x_0)$ calculated from (5.80) or (5.73). At $T = 0$, the curves have for $g \leq g_c$ two symmetric nontrivial minima at $\pm x_m$ with

$$x_m = \sqrt{\frac{1 - 3ga^2}{g}}, \quad (5.82)$$

where Eq. (5.79) becomes

$$\Omega^2(x_m) = 2 - 6ga^2(x_m). \quad (5.83)$$

These disappear for

$$g > g_c = \frac{4}{9} \sqrt{\frac{2}{3}} \approx 0.3629. \quad (5.84)$$

The resulting effective classical potentials and the free energies are plotted in Figs. 5.3 and 5.4.

It is useful to compare the approximate effective classical potential $W_1(x)$ with the true one $V^{\text{eff cl}}(x)$ in Fig. 5.5. The latter was obtained by Monte Carlo simulations of the path integral of the double-well potential, holding the path average $\bar{x} = (1/\beta) \int_0^\beta d\tau x(\tau)$ fixed at x_0 . The coupling strength is chosen as $g = 0.4$, where the worst agreement is expected.

In the limit $T \rightarrow 0$, the approximation F_1 yields an approximation $E_1^{(0)}$ for the ground state energy. In the strong-coupling limit, the leading behavior is the same as in Eq. (5.77) for the anharmonic oscillator.

Let us end this section with the following remark. The entire approximation procedure can certainly also be applied to a time-sliced path integral in which the time axis contains $N + 1$ discrete points $\tau_n = n\epsilon$, $n = 0, 1, \dots, N$. The only change in the above treatment consists in the replacement

$$\omega_m^2 \rightarrow \Omega_m \bar{\Omega}_m = \frac{1}{\epsilon^2} [2 - 2 \cos(\epsilon\omega_m)]. \quad (5.85)$$

Figure 5.3 Effective classical potential of double well $V(x) = -x^2/2 + gx^4/4 + 1/4g$ at various g for $T = 0$ and $T = \infty$ [where it is equal to the potential $V(x)$ itself]. The quantum fluctuations at $T = 0$ smear out the double well completely if $g \gtrsim 0.4$, but not if $g = 0.2$.

Hence the expression for the smearing square width parameter $a^2(x_0)$ of (5.24) is replaced by

$$\begin{aligned}
 a^2(x_0) &= \frac{2k_B T}{M} \frac{\partial}{\partial \Omega^2(x_0)} \log \prod_{m=1}^{m_{\max}} [\Omega_m \bar{\Omega}_m + \Omega^2(x_0)] \\
 &= \frac{k_B T}{M} \frac{1}{\Omega} \frac{\partial}{\partial \Omega} \log \frac{\sinh(\hbar \Omega_N(x_0)/2k_B T)}{\hbar \Omega(x_0)/2k_B T} \\
 &= \frac{k_B T}{M \Omega^2(x_0)} \left[\frac{\hbar \Omega(x_0)}{2k_B T} \coth \frac{\hbar \Omega_N(x_0)}{2k_B T} \frac{1}{\cosh(\epsilon \Omega_N(x_0)/2)} - 1 \right],
 \end{aligned} \tag{5.86}$$

where $m_{\max} = N/2$ for even and $(N - 1)/2$ for odd N [recall (2.391)], and $\Omega_N(x_0)$ is defined by

$$\sinh[\epsilon \Omega_N(x_0)/2] \equiv \epsilon \Omega(x_0)/2 \tag{5.87}$$

[see Eq. (2.399)]. The trial potential $W_1(x_0)$ now reads

$$W_1(x_0) \equiv k_B T \log \frac{\sinh \hbar \Omega_N(x_0)/2k_B T}{\hbar \Omega(x_0)/2k_B T} + V_{a^2(x_0)}(x_0) - \frac{M}{2} \Omega^2(x_0) a^2(x_0), \tag{5.88}$$

rather than (5.32). Minimizing this in $a^2(x_0)$ gives again (5.37) and (5.38) for $\Omega^2(x_0)$.

Figure 5.4 Free energy F_1 in double-well potential (5.78), compared with the exact free energy F_{ex} , the classical limit F_{cl} , and Feynman's approximation F_0 (which coincides with F_1 for the nonminimal values $\Omega = 0$, $a^2 = \beta/12$).

In Fig. 5.6 we have plotted the resulting approximate effective classical potential $W_1(x_0)$ of the double-well potential (5.78) with $g = 0.4$ at a fixed large value $\beta = 20$ for various numbers of lattice points $N + 1$. It is interesting to compare these plots with the exact curves, obtained again from Monte Carlo simulations. For $N = 1$, the agreement is exact. For small N , the agreement is good near and outside the potential minima. For larger N , the exact effective classical potential has oscillations which are not reproduced by the approximation.

5.8 Particle Densities

It is possible to find approximate particle densities from the optimal effective classical potential $W_1(x_0)$ [5, 6]. Certainly, the results cannot be as accurate as those for the free energies. In Schrödinger quantum mechanics, it is well known that variational methods can give quite accurate energies even if the trial wave functions are only of moderate quality. This has also been seen in the Eq. (5.53) estimate to the ground state energy of the Coulomb system by a Gaussian wave packet. The energy

Figure 5.5 Comparison of approximate effective classical potential $W_1(x_0)$ (dashed curves) and $W_3(x_0)$ (solid curves) with exact $V^{\text{eff cl}}(x_0)$ (dots) at various inverse temperatures $\beta = 1/T$. The data dots are obtained from Monte Carlo simulations using 10^5 configurations [W. Janke and H. Kleinert, Chem. Phys. Lett. 137, 162 (1987) (<http://www.physik.fu-berlin.de/~kleinert/154>)]. We have picked the worst case, $g = 0.4$. The solid lines represent the higher approximation $W_3(x_0)$, to be calculated in Section 5.13.

is a rather global property of the system. For physical quantities such as particle densities which contain local information on the wave functions, the approximation is expected to be much worse. Let us nevertheless calculate particle densities of a quantum-mechanical system. For this we tie down the periodic particle orbit in the trial partition function Z_1 for an arbitrary time at a particular position, say x_a . Mathematically, this is enforced with the help of a δ -function:

$$\begin{aligned} \delta(x_a - x(\tau)) &= \delta\left(x_a - x_0 - \sum_{m=1}^{\infty} (x_m e^{-i\omega_m \tau} + \text{c.c.})\right) \\ &= \int_{-\infty}^{\infty} \frac{dk}{2\pi} \exp\left\{ik \left[x_a - x_0 - \sum_{m=1}^{\infty} (x_m e^{-i\omega_m \tau} + \text{c.c.})\right]\right\}. \end{aligned} \quad (5.89)$$

ref(2.353) With this, we write the path integral for the particle density [compare (2.353)]
lab(2.length)
est(2.234)

$$\rho(x_a) = Z^{-1} \oint \mathcal{D}x \delta(x_a - x(\tau)) e^{-A/\hbar} \quad (5.90)$$

Figure 5.6 Effective classical potential $W_1(x_0)$ for double-well potential (5.78) with $g = 0.4$ at fixed low temperature $T = 1/\beta = 1/20$, for various numbers of time slices $N+1 = 2$ (■), 4 (△), 8 (▽), 16 (◇), 32 (+), 64 (□). The dashed line represents the original potential $V(x_0)$. For the source of the data points, see the previous figure caption.

and decompose

$$\begin{aligned} \rho(x_a) &= Z^{-1} \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \int \frac{dk}{2\pi} e^{ik(x_a-x_0)} \\ &\times \int \mathcal{D}x \tilde{\delta}(\bar{x} - x_0) e^{-ik \sum_{m=1}^{\infty} (x_m + \text{c.c.})} e^{-A/\hbar}. \end{aligned} \quad (5.91)$$

The approximation $W_1(x_0)$ is based on a quasiharmonic treatment of the x_m -fluctuations for $m > 0$. For harmonic fluctuations we use Wick's rule of Section 3.10 to evaluate

$$\left\langle e^{-ik \sum_{m=1}^{\infty} (x_m e^{-i\omega_m \tau} + \text{c.c.})} \right\rangle_{\Omega}^{x_0} \approx e^{-k^2 \sum_{m=1}^{\infty} \langle |x_m|^2 \rangle_{\Omega}^{x_0}} \equiv e^{-k^2 a^2/2}, \quad (5.92)$$

which is true for any τ . Thus we could have chosen any τ in the δ -function (5.89) to find the distribution function. Inserting (5.92) into (5.91) we can integrate out k and find the approximation to the particle density

$$\rho(x_a) \approx Z^{-1} \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \frac{e^{-(x_a-x_0)^2/2a^2(x_0)}}{\sqrt{2\pi a^2(x_0)}} e^{-V^{\text{eff cl}}(x_0)/k_B T}. \quad (5.93)$$

By inserting for $V^{\text{eff cl}}(x_0)$ the approximation $W_1(x_0)$, which for Z yields the approximation Z_1 , we arrive at the corresponding approximation for the particle distribution function:

$$\rho_1(x_a) = Z_1^{-1} \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} \frac{e^{-(x_a-x_0)^2/2a^2(x_0)}}{\sqrt{2\pi a^2(x_0)}} e^{-W_1(x_0)/k_B T}. \quad (5.94)$$

Figure 5.7 Approximate particle density (5.94;r:5.63;a:5.93) of anharmonic oscillator for $g = 40$, as compared with the exact density $\rho(x) = Z^{-1} \sum_n |\psi_n(x)|^2 e^{-\beta E_n}$, obtained by integrating the Schrödinger equation numerically. The curves are labeled by their β values with the subscripts 1, ex, cl indicating the approximation.

This has obviously the correct normalization $\int_{-\infty}^{\infty} dx_a \rho_1(x_a) = 1$. Figure 5.7 shows a comparison of the approximate particle distribution functions of the anharmonic oscillator with the exact ones. Both agree reasonably well with each other. In Fig. 5.8, the same plot is given for the double-well potential at a coupling $g = 0.4$. Here the agreement at very low temperature is not as good as in Fig. 5.7. Compare, for example, the zero-temperature curve ∞_1 with the exact curve ∞_{ex} . The first has only a single central peak, the second a double peak. The reason for this discrepancy is the correspondence of the approximate distribution to an optimal Gaussian wave function which happens to be centered at the origin, in spite of the double-well shape of the potential. In Fig. 5.3 we see the reason for this: The approximate effective classical potential $W_1(x_0)$ has, at small temperatures up to $T \sim 1/10$, only one minimum at the origin, and this becomes the center of the optimal Gaussian wave function. For larger temperatures, there are two minima and the approximate distribution function $\rho_1(x)$ corresponds roughly to two Gaussian wave packets centered around these minima. Then, the agreement with the exact distribution becomes better. We have intentionally chosen the coupling $g = 0.4$, where the result would be about the worst. For $g \gg 0.4$, both the true and the approximate distributions have a single central peak. For $g \ll 0.4$, both have two peaks at small temperatures. In both limits, the approximation is acceptable.

Figure 5.8 Particle density (5.94) in double-well potential (5.78) for the worst choice of the coupling constant, $g = 0.4$. Comparison is made with the exact density $\rho(x) = Z^{-1} \sum_n |\psi_n(x)|^2 e^{-\beta E_n}$ obtained by integrating the Schrödinger equation numerically. The curves are labeled by their β values with the subscripts 1, ex, cl indicating the approximation. For $\beta \rightarrow \infty$, the distribution tends to the Gaussian $e^{-x^2/2a^2} / \sqrt{2\pi a^2}$ with $a^2 = 1.030$ (see Table 5.1).

5.9 Extension to D Dimensions

The method can easily be extended to approximate the path integral of a particle moving in a D -dimensional \mathbf{x} -space. Let x_i be the D components of \mathbf{x} . Then the trial frequency $\Omega_{ij}^2(\mathbf{x}_0)$ in (5.7) must be taken as a $D \times D$ -matrix. In the special case of $V(\mathbf{x})$ being rotationally symmetric and depending only on $r = \sqrt{\mathbf{x}^2}$, we may introduce, as in the discussion of the effective action in Eqs. (3.684)–(3.689), longitudinal and transverse parts of $\Omega_{ij}^2(\mathbf{x}_0)$ via the decomposition

$$\Omega_{ij}^2(\mathbf{x}_0) = \Omega_L^2(r_0)P_{Lij}(\mathbf{x}_0) + \Omega_T^2(r_0)P_{Tij}(\mathbf{x}_0), \tag{5.95}$$

where

$$P_{Lij}(\hat{\mathbf{x}}_0) = x_{0i}x_{0j}/r_0^2, \quad P_{Tij}(\hat{\mathbf{x}}_0) = \delta_{ij} - x_{0i}x_{0j}/r_0^2, \tag{5.96}$$

are projection matrices into the longitudinal and transverse directions of \mathbf{x}_0 . Analogous projections of a vector are defined by $\mathbf{x}_L \equiv P_L(\mathbf{x}_0) \mathbf{x}$, $\mathbf{x}_T \equiv P_T(\mathbf{x}_0) \mathbf{x}$. Then the anisotropic generalization of $W_1^\Omega(\mathbf{x}_0)$ becomes

$$W_1^\Omega(r_0) = k_B T \left[\log \frac{\sinh \hbar \Omega_L / 2k_B T}{\hbar \Omega_L / 2k_B T} + (D - 1) \log \frac{\sinh \hbar \Omega_T / 2k_B T}{\hbar \Omega_T / 2k_B T} \right] - \frac{M}{2} \left[\Omega_L^2 a_L^2 + (D - 1) \Omega_T^2 a_T^2 \right] + V_{a_L, a_T}, \tag{5.97}$$

with all functions on the right-hand side depending only on r_0 . The bold-face superscript indicates the presence of two variational frequencies $\mathbf{\Omega} \equiv (\Omega_L, \Omega_T)$. The smeared potential is now given by

$$V_{a_L, a_T}(r_0) = \frac{1}{\sqrt{2\pi a_L^2}} \frac{1}{\sqrt{2\pi a_T^2}} \prod_{i=1}^{D-1} \left[\int_{-\infty}^{\infty} d\delta x_i \right] \times \exp \left[-\frac{1}{2} \left(a_L^{-2} \delta x_L^2 + a_T^{-2} \delta \mathbf{x}_T^2 \right) \right] V(\mathbf{x}_0 + \delta \mathbf{x}), \quad (5.98)$$

which can also be written as

$$V_{a_L, a_T}(r_0) = \frac{1}{\sqrt{(2\pi)^D a_L^2 a_T^{2D-2}}} \int d\delta x_L \int d^{D-1} \delta \mathbf{x}_T \exp \left[-\frac{\delta x_L^2}{2a_L^2} - \frac{\delta \mathbf{x}_T^2}{2a_T^2} \right] V(\mathbf{x}_0 + \delta \mathbf{x}). \quad (5.99)$$

For higher temperatures where the smearing widths a_L^2, a_T^2 are small, we set $V(\mathbf{x}) \equiv v(r^2)$, so that

$$V(\mathbf{x}) = v(r_0^2 + 2r_0\delta x_L + \delta x_L^2 + \delta \mathbf{x}_T^2) = \sum_{n=0}^{\infty} \frac{1}{n!} v^{(n)}(r_0^2) \left(2r_0\delta x_L + \delta x_L^2 + \delta \mathbf{x}_T^2 \right)^n = \left[v(r_0^2 + \partial_\lambda) e^{\lambda(2r_0\delta x_L + \delta x_L^2 + \delta \mathbf{x}_T^2)} \right]_{\lambda=0}. \quad (5.100)$$

Inserting this into the right-hand side of (5.98), we find

$$V_{a_L, a_T}(r_0) = \left[v(r_0^2 + \partial_\lambda) \frac{1}{\sqrt{1 - 2a_L^2\lambda}} \frac{1}{\sqrt{1 - 2a_T^2\lambda}} e^{2r_0^2\lambda^2 a_L^2 / (1 - 2a_L^2\lambda)} \right]_{\lambda=0}, \quad (5.101)$$

which has the expansion

$$V_{a_L, a_T}(r_0) = v(r_0^2) + v'(r_0^2)[a_L^2 + (D-1)a_T^2] + \frac{1}{2}v''(r_0^2)[3a_L^4 + 2(D-1)a_L^2a_T^2 + (D^2-1)a_T^4 + 4r_0^2a_L^2] + \dots \quad (5.102)$$

The prime abbreviates the derivative with respect to r_0^2 .

In general it is useful to insert into (5.98) the Fourier representation for the potential

$$V(\mathbf{x}) = \int \frac{d^D k}{(2\pi)^D} e^{i\mathbf{k}\mathbf{x}} V(\mathbf{k}), \quad (5.103)$$

which makes the \mathbf{x} -integration Gaussian, so that (5.99) becomes

$$V_{a_L^2, a_T^2}(r_0) = \int \frac{d^D k}{(2\pi)^D} V(\mathbf{k}) \exp \left(-\frac{a_L^2}{2} k_L^2 - \frac{a_T^2}{2} k_T^2 - ir_0 k_L \right). \quad (5.104)$$

Exploiting the rotational symmetry of the potential by writing $V(\mathbf{k}) \equiv v(k^2)$, we decompose the measure of integration as

$$\int \frac{d^D k}{(2\pi)^D} = \frac{S_{D-1}}{(2\pi)^D} \int_{-\infty}^{\infty} dk_L \int_0^{\infty} dk_T k_T^{D-2}, \quad (5.105)$$

where

$$S_D = \frac{2\pi^{D/2}}{\Gamma(D/2)} \quad (5.106)$$

is the surface of a sphere in D dimensions, and further with $k_L = k \cos \phi$, $k_T = k \sin \phi$:

$$\int \frac{d^D k}{(2\pi)^D} = \frac{S_{D-1}}{(2\pi)^D} \int_{-1}^1 d \cos \phi \int_0^\infty dk k^{D-1}. \quad (5.107)$$

This brings (5.104) to the form

$$\begin{aligned} V_{a_L^2, a_T^2}(r_0) &= \frac{S_{D-1}}{(2\pi)^D} \int_{-1}^1 du \int_{-1}^\infty dk k^{D-1} v(k^2) \\ &\quad \times \exp \left\{ -\frac{1}{2} \left[(a_L^2 u^2 + a_T^2 (1 - u^2)) k^2 - i r_0 u \right] \right\}. \end{aligned} \quad (5.108)$$

The final effective classical potential is found by minimizing $W_1(r_0)$ at each r_0 in $a_L, a_T, \Omega_L, \Omega_T$. To gain a rough idea about the solution, it is usually of advantage to study first the *isotropic approximation* obtained by assuming $a_T^2(r_0) = a_L^2(r_0)$, and to proceed later to the anisotropic approximation.

5.10 Application to Coulomb and Yukawa Potentials

The effective classical potential can be useful also for singular potentials as long as the smearing procedure makes sense. An example is the Yukawa potential

$$V(r) = -(e^2/r)e^{-mr}, \quad (5.109)$$

which reduces to the Coulomb potential for $m \equiv 0$. Using the Fourier representation

$$V(r) = 4\pi \int \frac{d^3 k}{(2\pi)^3} \frac{e^{i\mathbf{k}\mathbf{x}}}{k^2 + m^2} = 4\pi \int_0^\infty d\tau \int \frac{d^3 k}{(2\pi)^3} e^{-\tau(k^2 + m^2)}, \quad (5.110)$$

we easily calculate the isotropically smeared potential

$$\begin{aligned} V_{a^2}(r_0) &= -e^2 \int \frac{d^3 x}{\sqrt{2\pi a^2}^3} \exp \left[-\frac{1}{2a^2} (\mathbf{x}_0 - \mathbf{x})^2 \right] V(r) \\ &= -e^2 2\pi e^{m^2 a^2/2} \int_{a^2}^\infty da'^2 \frac{1}{\sqrt{2\pi a'^2}^3} \exp \left(-r_0^2/2a'^2 - m^2 a'^2/2 \right) \\ &= -e^2 \frac{2e^{m^2 a^2/2}}{\sqrt{\pi}} \frac{1}{r_0} \int_0^{r_0/\sqrt{2a^2}} dt e^{-(t^2 + m^2 r_0^2/4t^2)}. \end{aligned} \quad (5.111)$$

In the Coulomb limit $m \rightarrow 0$, the smeared potential becomes equal to the Coulomb potential multiplied by an error function,

$$V_{a^2}(r_0) = -\frac{e^2}{r_0} \operatorname{erf}(r_0/\sqrt{2a^2}), \quad (5.112)$$

where the error function is defined by

$$\operatorname{erf}(z) \equiv \frac{2}{\sqrt{\pi}} \int_0^z dx e^{-x^2}. \quad (5.113)$$

The smeared potential is no longer singular at the origin,

$$V_{a^2}(0) = -\frac{e^2}{a} \sqrt{\frac{2}{\pi}} e^{m^2 a^2/2}. \quad (5.114)$$

The singularity has been removed by quantum fluctuations. In this way the effective classical potential explains the stability of matter in quantum physics, i.e., the fact that atomic electrons do not fall into the origin. The effective classical potential of the Coulomb system is then by the isotropic version of (5.97)

$$W_1^\Omega(\mathbf{x}_0) = \frac{3}{\beta} \ln \frac{\sinh[\hbar\beta\Omega(\mathbf{x}_0)/2]}{\hbar\beta\Omega(\mathbf{x}_0)/2} - \frac{e^2}{|\mathbf{x}_0|} \operatorname{erf} \left[\frac{|\mathbf{x}_0|}{\sqrt{2a^2(\mathbf{x}_0)}} \right] - \frac{3}{2} M\Omega^2(\mathbf{x}_0)a^2(\mathbf{x}_0). \quad (5.115)$$

Minimizing $W_1(r_0)$ with respect to $a^2(r_0)$ gives an equation analogous to Eq. (5.37) determining the frequency $\Omega^2(r_0)$ to be

$$\Omega^2(r_0) = e^2 \frac{2}{3} \frac{1}{\sqrt{2\pi}} \frac{1}{(a^2)^{3/2}} e^{-r_0^2/2a^2}. \quad (5.116)$$

We have gone to atomic units in which $e = M = \hbar = k_B = 1$, so that energies and temperatures are measured in units of $E_0 = Me^4/M\hbar^2 \approx 4.36 \times 10^{-11} \text{erg} \approx 27.21 \text{eV}$ and $T_0 = E_0/k_B \approx 31575 \text{K}$, respectively. Solving (5.116) together with (5.24), we find $a^2(r_0)$ and the approximate effective classical potential (5.32). The result is shown in Fig. 5.9 as a dashed curve. The above approximation may now be improved by treating the fluctuations anisotropically, as described in the previous section, with different $\Omega^2(\mathbf{x}_0)$ for radial and tangential fluctuations $\delta\mathbf{x}_L$ and $\delta\mathbf{x}_T$, and the effective potential following Eqs. (5.97) and (5.98). For the anisotropically smeared Coulomb potential we calculate from (5.108):

$$V_{a_L^2, a_T^2}(r_0) = -\sqrt{\frac{1}{2\pi}} \int_{-1}^1 du \frac{e^2}{\sqrt{a_L^2 u^2 + a_T^2(1-u^2)}} \exp \left\{ -\frac{r_0^2 u^2}{2[a_L^2 u^2 + a_T^2(1-u^2)]} \right\}. \quad (5.117)$$

Introducing the variable $\lambda = \sqrt{a_L^2 u} / \sqrt{a_L^2 \lambda^2 + a_T^2(1-\lambda^2)}$, which runs through the same interval $[-1, 1]$ as u , we rewrite this as

$$V_{a_L^2, a_T^2}(r_0) = -e^2 \sqrt{\frac{a_L^2}{2\pi}} \int_{-1}^1 d\lambda \frac{\exp[-(r_0^2/2a_L^2)\lambda^2]}{a_L^2(1-\lambda^2) + a_T^2\lambda^2}. \quad (5.118)$$

Figure 5.9 Approximate effective classical potential $W_1(r_0)$ of Coulomb system at various temperatures (in multiples of 10^4K). It is calculated once in the isotropic (dashed curves) and once in the anisotropic approximation. The improvement is visible in the insert which shows W_1/V . The inverse temperature values of the different curves are $\beta = 31.58, 15.78, 7.89, 3.945, 1.9725, 0.9863, 0$ atomic units, respectively.

Extremization of $W_1(r_0)$ in Eq. (5.97) yields the equations for the trial frequencies

$$\Omega_T^2(r_0) \equiv \frac{\partial}{\partial a_T^2} V_{a_T^2, a_L^2} = e^2 \sqrt{\frac{a_L^2}{2\pi}} \int_{-1}^1 d\lambda \frac{\lambda^2 \exp[-(r_0^2/2a_L^2)\lambda^2]}{[a_L^2(1-\lambda^2) + a_T^2\lambda^2]^2}, \quad (5.119)$$

$$\begin{aligned} \Omega^2(r_0) &\equiv \frac{1}{3}[\Omega_L^2 + 2\Omega_T^2] = \frac{1}{3} \left[\frac{\partial}{\partial a_L^2} + 2\frac{\partial}{\partial a_T^2} \right] V_{a_T^2, a_L^2} \\ &= e^2 \frac{2}{3} \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{a_L^2 a_T^4}} \exp(-r_0^2/2a_L^2). \end{aligned} \quad (5.120)$$

These equations have to be solved together with

$$a_{L,T}^2(r_0) = \frac{1}{\beta\Omega_{L,T}^2(r_0)} \left[\frac{\beta\Omega_{L,T}(r_0)}{2} \coth \frac{\beta\Omega_{L,T}(r_0)}{2} - 1 \right]. \quad (5.121)$$

Upon inserting the solutions into (5.97), we find the approximate effective classical potential plotted in Fig. 5.9 as a solid curve. Let us calculate the approximate particle distribution functions using a three-dimensional anisotropic version of Eq. (5.94). With the potential $W_1(r_0)$, we arrive at the integral [6]

$$\rho_1(r) = \int d^3x_0 \frac{e^{-(z_0-r)^2/2a_L^2} e^{-(x_0^2+y_0^2)/2a_T^2} e^{-\beta W_1(r_0)}}{\sqrt{2\pi a_L^2(r_0)} \frac{1}{2\pi a_T^2(r_0)} (2\pi\beta)^{3/2}}$$

Figure 5.10 Particle distribution $g(r) \equiv \sqrt{2\pi\beta^3}\rho(r)$ in Coulomb potential at different temperatures T (the same as in Fig. 5.9), calculated once in the isotropic and once in the anisotropic approximation. The dotted curves show the classical distribution. For low and intermediate temperatures the exact distributions of R.G. Storer, *J. Math. Phys.* 9, 964 (1968) are well represented by the two lowest energy levels for which $\rho(r) = \pi^{-1}e^{-2r}e^{\beta/2} + (1/8\pi)(1 - r + r^2/2)e^{-r}e^{\beta/8} + (1/3^8\pi)(243 - 324r + 216r^2 - 48r^3 + 4r^4)e^{-2r/3}e^{\beta/18}$.

$$= 2\pi \int_0^\infty dr_0 \int_{-1}^1 d\lambda \frac{e^{-(\lambda r_0 - r)^2/2a_L^2} e^{-r_0^2(1-\lambda^2)/2a_T^2} e^{-\beta W_1(r_0)}}{\sqrt{2\pi a_L^2(r_0)} \cdot 2\pi a_T^2(r_0) \cdot (2\pi\beta)^{3/2}}. \quad (5.122)$$

The resulting curves to different temperatures are plotted in Fig. 5.10 and compared with the exact distribution as given by Storer. The distribution obtained from the earlier isotropic approximation (5.116) to the trial frequency $\Omega^2(r_0)$ is also shown.

5.11 Hydrogen Atom in Strong Magnetic Field

The recent discovery of magnetars [7] has renewed interest in the behavior of charged particle systems in the presence of extremely strong external magnetic fields. In this new type of neutron stars, electrons and protons from decaying neutrons produce magnetic fields B reaching up to 10^{15} G, much larger than those in neutron stars and white dwarfs, where B is of order $10^{10} - 10^{12}$ G and $10^6 - 10^8$ G, respectively.

Analytic treatments of the strong-field properties of an atomic system are difficult, even in the zero-temperature limit. The reason is a logarithmic asymptotic behavior of the ground state energy to be derived in Eq. (5.132). In the weak-field

limit, on the other hand, perturbative approaches yield well-known series expansions in powers of B^2 up to B^{60} [8]. These are useful, however, only for $B \ll B_0$, where B_0 is the atomic magnetic field strength $B_0 = e^3 M^2 / \hbar^3 \approx 2.35 \times 10^5 \text{ T} = 2.35 \times 10^9 \text{ G}$.

So far, the most reliable values for strong uniform fields were obtained by numerical calculations [9].

The variational approach can be used to derive a single analytic expression for the effective classical potential applicable to all field strengths and temperatures [10]. The Hamiltonian of the electron in a hydrogen atom in a uniform external magnetic field pointing along the positive z -axis is the obvious extension of the expression in Eq. (2.646) by a Coulomb potential:

$$H(\mathbf{p}, \mathbf{x}) = \frac{1}{2M} \mathbf{p}^2 + \frac{M}{2} \omega_B^2 \mathbf{x}^2 - \omega_B l_z(\mathbf{p}, \mathbf{x}) - \frac{e^2}{|\mathbf{x}|}, \quad (5.123)$$

where ω_B denotes the B -dependent magnetic frequency $\omega_L/2 = eB/2Mc$ of Eq. (2.651), i.e., half the Landau or cyclotron frequency. The magnetic vector potential has been chosen in the symmetric gauge (2.640). Recall that l_z is the z -component of the orbital angular momentum $l_z(\mathbf{p}, \mathbf{x}) = (\mathbf{x} \times \mathbf{p})_z$ [see (2.647)].

At first, we restrict ourselves here to zero temperature. From the imaginary-time version of the classical action (2.640) we see that the particle distribution function in the orthogonal direction of the magnetic field is, for $x_b = 0, y_b = 0$, proportional to

$$\exp\left(-\frac{M}{2} \omega_B \mathbf{x}_a^2\right). \quad (5.124)$$

This is the same distribution as for a transverse harmonic oscillator with frequency ω_B . Being at zero temperature, the first-order variational energy requires knowing the smeared potential at the origin. Allowing for a different smearing width a_{\parallel}^2 and a_{\perp}^2 along an orthogonal to the magnetic field, we may use Eq. (5.118) to write

$$V_{a_{\parallel}^2, a_{\perp}^2}(0) = -e^2 \sqrt{\frac{1}{2\pi a_{\parallel}^2}} \int_{-1}^1 d\lambda \frac{1}{(1-\lambda^2) + \lambda^2 a_{\perp}^2 / a_{\parallel}^2}. \quad (5.125)$$

Performing the integral yields

$$V_{a_{\parallel}^2, a_{\perp}^2}(0) = -e^2 \sqrt{\frac{1}{2\pi(a_{\parallel}^2 - a_{\perp}^2)}} 2 \operatorname{arccosh} \frac{a_{\parallel}}{a_{\perp}}. \quad (5.126)$$

Since the ground state energies of the parallel and orthogonal oscillators are $\Omega_{\parallel}/2$ and $2 \times \Omega_{\perp}/2$, we obtain immediately the first-order variational energy

$$W_1(\mathbf{0}) = \Omega_{\perp} + \frac{\Omega_{\parallel}}{2} + V_{a_{\parallel}^2, a_{\perp}^2}(\mathbf{0}) + \frac{M}{2} (\omega_{\parallel}^2 - \Omega_{\parallel}^2) a_{\parallel}^2 + M (\omega_B^2 - \Omega_{\perp}^2) a_{\perp}^2, \quad (5.127)$$

with $\omega_{\parallel} = 0$ and $a_{\parallel, \perp}^2 = 1/2\Omega_{\parallel, \perp}$. In this expression we have ignored the second term in the Hamiltonian (5.123), since the angular momentum l_z of the ground state must have a zero expectation value.

For very strong magnetic fields, the transverse variational frequency Ω_T will become equal to $\omega_B = \hbar e/2Mc$, such that in this limit

$$W(\mathbf{0}) \approx \omega_B + \frac{\Omega_{\parallel}}{4} - e^2 \sqrt{\frac{\Omega_{\parallel}}{\pi}} \log \frac{8\omega_B}{\Omega_{\parallel}}. \quad (5.128)$$

Extremizing this in Ω_{\parallel} yields

$$\Omega_{\parallel} \approx \frac{4e^4}{\pi} \log^2 \frac{2\pi\omega_B}{e^4}, \quad (5.129)$$

and thus an approximate ground state energy

$$E_1^{(0)} \approx \omega_B - \frac{e^4}{\pi} \log^2 \frac{2\pi\omega_B}{e^4}. \quad (5.130)$$

The approach to very strong fields can be found by extremizing the energy (5.127) also in Ω_{\perp} . Going over to atomic units with $e = 1$ and $M = 1$, where energies are measured in units of $\epsilon_0 = Me^4/\hbar^2 \equiv 2 \text{ Ryd} \approx 27.21 \text{ eV}$, temperatures in $\epsilon_0/k_B \approx 3.16 \times 10^5 \text{ K}$, distances in Bohr radii $a_B = \hbar^2/Me^2 \approx 0.53 \times 10^{-8} \text{ cm}$, and magnetic field strengths in $B_0 = e^3 M^2/\hbar^3 \approx 2.35 \times 10^5 \text{ T} = 2.35 \times 10^9 \text{ G}$, the extremization yields

$$\Omega_{\parallel} \approx \frac{B}{2}, \quad \sqrt{\Omega_{\perp}} = \frac{2}{\sqrt{\pi}} \left(\ln B - 2 \ln \ln B + \frac{2a}{\ln B} + \frac{a^2}{\ln^2 B} + b \right) + \mathcal{O}(\ln^{-3} B), \quad (5.131)$$

with abbreviations $a = 2 - \ln 2 \approx 1.307$ and $b = \ln(\pi/2) - 2 \approx -1.548$. The associated optimized ground state energy is, up to terms of order $\ln^{-2} B$,

$$E^{(0)}(B) = \frac{B}{2} - \frac{1}{\pi} \left\{ \ln^2 B - 4 \ln B \ln \ln B + 4 \ln^2 \ln B - 4b \ln \ln B + 2(b+2) \ln B + b^2 - \frac{1}{\ln B} [8 \ln^2 \ln B - 8b \ln \ln B + 2b^2] \right\} + \mathcal{O}(\ln^{-2} B). \quad (5.132)$$

The prefactor $1/\pi$ of the leading $\ln^2 B$ -term using a variational ansatz of the type (5.64), (5.65) for the transverse degree of freedom is in contrast to the value $1/2$ calculated in the textbook by Landau and Lifshitz [11]. The calculation of higher orders in variational perturbation theory would drive our value towards $1/2$.

The convergence of the expansion (5.132) is quite slow. At a magnetic field strength $B = 10^5 B_0$, which corresponds to $2.35 \times 10^{10} \text{ T} = 2.35 \times 10^{14} \text{ G}$, the contribution from the first six terms is $22.87 [2 \text{ Ryd}]$. The next three terms suppressed by a factor $\ln^{-1} B$ contribute $-2.29 [2 \text{ Ryd}]$, while an estimate for the $\ln^{-2} B$ -terms yields nearly $-0.3 [2 \text{ Ryd}]$. Thus we find $\varepsilon^{(1)}(10^5) = 20.58 \pm 0.3 [2 \text{ Ryd}]$.

Table 5.2 lists the values of the first six terms of Eq. (5.132). This shows in particular the significance of the second term in (5.132), which is of the same order of the leading first term, but with an opposite sign.

Table 5.2 Example for competing leading six terms in large- B expansion (5.132) at $B = 10^5 B_0 \approx 2.35 \times 10^{14}$ G.

$(1/\pi)\ln^2 B$	$-(4/\pi)\ln B \ln \ln B$	$(4/\pi)\ln^2 \ln B$	$-(4b/\pi)\ln \ln B$	$[2(b+2)/\pi]\ln B$	b^2/π

Figure 5.11 First-order variational result for binding energy (5.133) as a function of the strength of the magnetic field. The dots indicate the values derived in the reference given in Ref. [12]. The long-dashed curve on the left-hand side shows the simple estimate $0.5\ln^2 B$ of the textbook by Landau and Lifshitz [11]. The right-hand side shows the successive approximations from the strong-field expansion (5.134) for $N = 0, 1, 2, 3, 4$, with decreasing dash length. Fat curve is our variational approximation.

The field dependence of the binding energy

$$\epsilon(B) \equiv \frac{B}{2} - E^{(0)} \tag{5.133}$$

is plotted in Fig. 5.11, where it is compared with the results of other authors who used completely different methods, with satisfactory agreement [12]. On the strong-coupling side we have plotted successive orders of a strong-field expansion [24]. The curves result from an iterative solution of the sequence of implicit equations for the quantity $w(B) = \sqrt{\epsilon(4B)/2}$ for $N = 1, 2, 3, 4$:

$$w = \frac{1}{2} \log \frac{B}{w^2} + \sum_{n=1}^N a_n(B, w), \tag{5.134}$$

where

$$a_1 \equiv -\frac{1}{2}(\gamma + \log 2), \quad a_2 \equiv \frac{\pi^2}{12w}, \quad a_3 \equiv -\sqrt{\frac{2}{B}} \left(\log \frac{B}{2w^2} - \sqrt{\pi}w \right), \quad a_4 = \sqrt{\frac{2}{B}} \frac{\sqrt{\pi}}{2} D, \tag{5.135}$$

and D denotes the integral $D \equiv \gamma - 2 \int_0^\infty dy (y/\sqrt{y^2+1} - 1) \log y \approx -0.03648$, where $\gamma \approx 0.5773$ is the Euler-Mascheroni constant (2.469).

Our results are of similar accuracy as those of other first-order calculations based on an operator optimization method [25]. The advantage of our variational approach is that it yields good results for all magnetic field strengths and temperatures, and that it can be improved systematically by methods to be developed in Section 5.13, with rapid convergence. The figure shows also the energy of Landau and Lifshitz which grossly overestimates the binding energies even at very large magnetic fields, such as $2000B_0 \propto 10^{12}$ G. Obviously, the nonleading terms in Eq. (5.132) give important contributions to the asymptotic behavior even at such large magnetic fields. As a peculiar property of the asymptotic behavior, the absolute value of the difference between the Landau-Lifshitz result and our approximation (5.132) diverges with increasing magnetic field strengths B . Only the relative difference decreases.

5.11.1 Weak-Field Behavior

Let us also calculate the weak-field behavior of the variational energy (5.127). Setting $\eta \equiv \Omega_{\parallel}/\Omega_{\perp}$, we rewrite $W_1(\mathbf{0})$ as

$$W_1(\mathbf{0}) = \frac{\Omega_{\perp}}{2} \left(1 + \frac{\eta}{2}\right) + \frac{B^2}{8\Omega_{\perp}} + \sqrt{\frac{\eta\Omega_{\perp}}{\pi}} \frac{1}{\sqrt{1-\eta}} \ln \frac{1 - \sqrt{1-\eta}}{1 + \sqrt{1-\eta}}. \quad (5.136)$$

This is minimized in η and Ω_{\perp} by expanding $\eta(B)$ and $\Omega(B)$ in powers of B^2 with unknown coefficients, and inserting these expansions into extremality equations. The expansion coefficients are then determined order by order. The optimal expansions are inserted into (5.136), yielding the optimized binding energy $\varepsilon^{(1)}(B)$ as a power series

$$W_1(\mathbf{0}) = \sum_{n=0}^{\infty} \varepsilon_n B^{2n}. \quad (5.137)$$

The coefficients ε_n are listed in Table 5.3 and compared with the exact ones. Of course, the higher-order coefficients of this first-order variational approximation become rapidly inaccurate, but the results can be improved, if desired, by going to higher orders in variational perturbation theory of Section 5.13.

5.11.2 Effective Classical Hamiltonian

The quantum statistical properties of the system at an arbitrary temperature are contained in the effective classical potential $H^{\text{eff cl}}(\mathbf{p}_0, \mathbf{x}_0)$ defined by the three-dimensional version of Eq. (3.824):

$$B(\mathbf{p}_0, \mathbf{x}_0) \equiv e^{-\beta H^{\text{eff cl}}(\mathbf{p}_0, \mathbf{x}_0)} \equiv \oint \mathcal{D}^3 x \oint \frac{\mathcal{D}^3 p}{(2\pi\hbar)^3} \delta^{(3)}(\mathbf{x}_0 - \bar{\mathbf{x}}) (2\pi\hbar)^3 \delta(\mathbf{p}_0 - \bar{\mathbf{p}}) e^{-\mathcal{A}[\mathbf{p}, \mathbf{x}]/\hbar}, \quad (5.138)$$

Table 5.3 Perturbation coefficients up to order B^6 in weak-field expansions of variational parameters, and binding energy in comparison to exact ones (from J.E. Avron et al. and B.G. Adams et al. quoted in Notes and References).

n	0	1	2	3
η_n	1.0	$-\frac{405\pi^2}{7168} \approx -0.5576$	$\frac{16828965\pi^4}{1258815488} \approx 1.3023$	$-\frac{3886999332075\pi^6}{884272562962432} \approx -4.2260$
Ω_n	$\frac{32}{9\pi} \approx 1.1318$	$\frac{99\pi}{224} \approx 1.3885$	$-\frac{1293975\pi^3}{19668992} \approx -2.03982$	$\frac{524431667187\pi^5}{27633517592576} \approx 5.8077$
ε_n	$-\frac{4}{3\pi} \approx -0.4244$	$\frac{9\pi}{128} \approx 0.2209$	$-\frac{8019\pi^3}{1835008} \approx -0.1355$	$\frac{256449807\pi^5}{322256764928} \approx 0.2435$
$\varepsilon_n^{\text{ex}}$	-0.5	0.25	$-\frac{53}{192} \approx -0.2760$	$\frac{5581}{4608} \approx 1.2112$

where $\mathcal{A}_e[\mathbf{p}, \mathbf{x}]$ is the Euclidean action

$$\mathcal{A}_e[\mathbf{p}, \mathbf{x}] = \int_0^{\hbar\beta} d\tau [-i\mathbf{p}(\tau)\dot{\mathbf{x}}(\tau) + H(\mathbf{p}(\tau), \mathbf{x}(\tau))], \tag{5.139}$$

and $\bar{\mathbf{x}} = \int_0^{\hbar\beta} d\tau \mathbf{x}(\tau)/\hbar\beta$ and $\bar{\mathbf{p}} = \int_0^{\hbar\beta} d\tau \mathbf{p}(\tau)/\hbar\beta$ are the temporal averages of position and momentum. Note that the deviations of $\mathbf{p}(\tau)$ from the average \mathbf{p}_0 share with $\mathbf{x}(\tau) - \mathbf{x}_0$ the property that the averages of the squares go to zero with increasing temperatures like $1/T$, and remains finite for $T \rightarrow 0$. while the expectation of \mathbf{p}^2 grows linearly with T (Dulong-Petit law). For $T \rightarrow 0$, the averages of the squares of $\mathbf{p}(\tau)$ remain finite. This property is the basis for a reliable accuracy of the variational treatment.

Thus we separate the action (5.139) (omitting the subscript e) as

$$\mathcal{A}_e[\mathbf{p}, \mathbf{x}] = \beta H(\mathbf{p}_0, \mathbf{x}_0) + \mathcal{A}_\Omega^{\mathbf{p}_0, \mathbf{x}_0}[\mathbf{p}, \mathbf{x}] + \mathcal{A}_{\text{int}}[\mathbf{p}, \mathbf{x}], \tag{5.140}$$

where $\mathcal{A}_\Omega^{\mathbf{p}_0, \mathbf{x}_0}[\mathbf{p}, \mathbf{x}]$ is the most general harmonic trial action containing the magnetic field. It has the form (3.828), except that we use capital frequencies to emphasize that they are now variational parameters:

$$\begin{aligned} \mathcal{A}_\Omega^{\mathbf{p}_0, \mathbf{x}_0}[\mathbf{p}, \mathbf{x}] = & \int_0^{\hbar\beta} d\tau \left\{ -i[\mathbf{p}(\tau) - \mathbf{p}_0] \cdot \dot{\mathbf{x}}(\tau) + \frac{1}{2M}[\mathbf{p}(\tau) - \mathbf{p}_0]^2 \right. \\ & \left. + \Omega_B l_z(\mathbf{p}(\tau) - \mathbf{p}_0, \mathbf{x}(\tau) - \mathbf{x}_0) + \frac{M}{2}\Omega_\perp^2 [\mathbf{x}_\perp(\tau) - \mathbf{x}_{0\perp}]^2 + \frac{M}{2}\Omega_\parallel^2 [z(\tau) - z_0]^2 \right\}. \end{aligned} \tag{5.141}$$

The vector $\mathbf{x}^\perp = (x, y)$ is the projection of \mathbf{x} orthogonal to \mathbf{B} .

The trial frequencies $\Omega = (\Omega_B, \Omega_\perp, \Omega_\parallel)$ are arbitrary functions of $\mathbf{p}_0, \mathbf{x}_0$, and \mathbf{B} . Inserting the decomposition (5.140) into (5.138), we expand the exponential of the interaction, $\exp\{-\mathcal{A}_{\text{int}}[\mathbf{p}, \mathbf{x}]/\hbar\}$, and obtain a series of expectation values of powers of the interaction $\langle \mathcal{A}_{\text{int}}^n[\mathbf{p}, \mathbf{x}] \rangle_\Omega^{\mathbf{p}_0, \mathbf{x}_0}$, defined in general by the path integral

$$\begin{aligned} \langle \mathcal{O}[\mathbf{p}, \mathbf{x}] \rangle_\Omega^{\mathbf{p}_0, \mathbf{x}_0} = & \frac{1}{Z_\Omega^{\mathbf{p}_0, \mathbf{x}_0}} \int \mathcal{D}^3x \frac{\mathcal{D}^3p}{(2\pi\hbar)^3} \mathcal{O}[\mathbf{p}, \mathbf{x}] \delta^{(3)}(\mathbf{x}_0 - \bar{\mathbf{x}})(2\pi\hbar)^3 \delta(\mathbf{p}_0 - \bar{\mathbf{p}}) \\ & \times \exp\left\{-\frac{1}{\hbar} \mathcal{A}_\Omega^{\mathbf{p}_0, \mathbf{x}_0}[\mathbf{p}, \mathbf{x}]\right\}, \end{aligned} \tag{5.142}$$

where the local partition function in phase space $Z_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}$ is the normalization factor which ensures that $\langle 1 \rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0} = 1$. From Eq. (3.829) we know that

$$Z_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0} \equiv e^{-\beta F_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}} = l_e^3(\hbar\beta) \frac{\hbar\beta\Omega_+/2}{\sinh \hbar\beta\Omega_+/2} \frac{\hbar\beta\Omega_-/2}{\sinh \hbar\beta\Omega_-/2} \frac{\hbar\beta\Omega_{\parallel}/2}{\sinh \hbar\beta\Omega_{\parallel}/2}, \quad (5.143)$$

where $\Omega_{\pm} \equiv \Omega_B \pm \Omega_{\perp}$. In comparison to (3.829), the classical Boltzmann factor $e^{-\beta H(\mathbf{p}_0, \mathbf{x}_0)}$ is absent due to the shift of the integration variables in the action (5.141). Note that the fluctuations $\mathbf{p}(\tau) - \mathbf{p}_0$ decouple from \mathbf{p}_0 just as $\mathbf{x}(\tau) - \mathbf{x}_0$ decoupled from \mathbf{x}_0 due to the absence of zero frequencies in the fluctuations.

Rewriting the perturbation series as a cumulant expansion, evaluating the expectation values, and integrating out the momenta on the right-hand side of Eq. (5.138) leads to a series representation for the effective classical potential $V_{\text{eff}}(\mathbf{x}_0)$. Since it is impossible to sum up the series, the perturbation expansion must be truncated, leading to an N th-order approximation $W_{\Omega}^{(N)}(\mathbf{x}_0)$ for the effective classical potential. Since the parameters Ω are arbitrary, $W_{\Omega}^{(N)}(\mathbf{x}_0)$ should depend *minimally* on Ω . This determines the optimal values of Ω to be equal to $\Omega^{(N)}(\mathbf{x}_0) = (\Omega_B^{(N)}(\mathbf{x}_0), \Omega_{\perp}^{(N)}(\mathbf{x}_0), \Omega_{\parallel}^{(N)}(\mathbf{x}_0))$ of N th order. Reinserting these into $W_{\Omega}^{(N)}(\mathbf{x}_0)$ yields the optimal approximation $W^{(N)}(\mathbf{x}_0) \equiv W_{\Omega^{(N)}}^{(N)}(\mathbf{x}_0)$.

The first-order approximation to the effective classical potential is then, with $\omega_{\parallel} = 0, \omega_{\perp} = \omega_B$,

$$\begin{aligned} W_{\Omega}^{(1)}(\mathbf{x}_0) &= F_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0} - \frac{M}{2} \Omega_B(\mathbf{x}_0) [\omega_B - \Omega_B(\mathbf{x}_0)] b_{\perp}^2(\mathbf{x}_0) a_{\perp}^2(\mathbf{x}_0) \\ &+ \frac{M}{2} [\omega_B^2 - \Omega_{\perp}^2(\mathbf{x}_0)] - \frac{1}{2} \Omega_{\parallel}^2 a_{\parallel}^2(\mathbf{x}_0) - \left\langle \frac{e^2}{|\mathbf{x}|} \right\rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}. \end{aligned} \quad (5.144)$$

The smearing of the Coulomb potential is performed as in Section 5.10. This yields the result (5.117). with the longitudinal width

$$a_{\parallel}^2(\mathbf{x}_0) = G_{zz}^{(2)\mathbf{x}_0}(\tau, \tau) = \frac{1}{\beta M \Omega_{\parallel}^2(\mathbf{x}_0)} \left[\frac{\hbar\beta\Omega_{\parallel}(\mathbf{x}_0)}{2} \coth \frac{\hbar\beta\Omega_{\parallel}(\mathbf{x}_0)}{2} - 1 \right], \quad (5.145)$$

and an analog transverse width.

The quantity $b_{\perp}^2(\mathbf{x}_0)$ is new in this discussion based on the canonical path integral. It denotes the expectation value associated with the z -component of the angular momentum

$$b_{\perp}^2(\mathbf{x}_0) \equiv \frac{1}{M\Omega_B} \langle l_z \rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}, \quad (5.146)$$

which can also be written as

$$b_{\perp}^2(\mathbf{x}_0) = \frac{2}{M\Omega_{T1}} \langle x(\tau)p_y(\tau) \rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}. \quad (5.147)$$

According to Eq. (3.358), the correlation function $\langle x(\tau)p_y(\tau) \rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0}$ is given by

$$\langle x(\tau)p_y(\tau') \rangle_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0} = iM\partial_{\tau'} G_{\omega^2, B, xx}^{(2)}(\tau, \tau') - M\omega_B G_{\omega^2, B, xy}^{(2)}(\tau, \tau'), \quad (5.148)$$

Figure 5.12 Effective classical potential of atom in strong magnetic field plotted along two directions: once as a function of the coordinate $\rho_0 = \sqrt{x_0^2 + y_0^2}$ perpendicular to the field lines at $z_0 = 0$ (solid curves), and once parallel to the magnetic field as a function of z_0 at $\rho_0 = 0$ (dashed curves). The inverse temperature is fixed at $\beta = 100$, and the strengths of the magnetic field B are varied (all in natural units).

where the expressions on the right-hand side are those of Eqs. (3.329) and (3.331), with ω replaced by Ω .

The variational energy (5.144) is minimized at each \mathbf{x}_0 , and the resulting $W^{(N)}(\mathbf{x}_0)$ is displayed for a low temperature and different magnetic fields in Fig. 5.12. The plots show the anisotropy with respect to the magnetic field direction. The anisotropy grows when lowering the temperature and increasing the field strength. Far away from the proton at the origin, the potential becomes isotropic, due to the decreasing influence of the Coulomb interaction. Analytically, this is seen by going to the limits $\rho_0 \rightarrow \infty$ or $z_0 \rightarrow \infty$, where the expectation value of the Coulomb potential tends to zero, leaving an effective classical potential

$$W_{\Omega}^{(1)}(\mathbf{x}_0) \rightarrow F_{\Omega}^{\mathbf{p}_0, \mathbf{x}_0} - M\Omega_B(\omega_{\perp} - \Omega_B)b_{\perp}^2 + M(\omega_{\perp}^2 - \Omega_{\perp}^2)a_{\perp}^2 - \frac{M}{2}\Omega_{\parallel}^2 a_{\parallel}^2. \quad (5.149)$$

This is \mathbf{x}_0 -independent, and optimization yields the constants $\Omega_B^{(1)} = \Omega_{\perp}^{(1)} = \omega_B$ and $\Omega_{\parallel}^{(1)} = 0$, with the asymptotic energy

$$W^{(1)}(\mathbf{x}_0) \rightarrow -\frac{1}{\beta} \log \frac{\beta \hbar \omega_B}{\sinh \beta \hbar \omega_B}. \quad (5.150)$$

The $B = 0$ -curves agree, of course, with those obtained from the previous variational perturbation theory of the hydrogen atom [26].

For large temperatures, the anisotropy decreases since the violent thermal fluctuations have a smaller preference of the z -direction.

5.12 Variational Approach to Excitation Energies

As explained in Section 5.4, the success of the above variational treatment is rooted in the fact that for smooth potentials, the ground state energy can be approximated quite well by the optimal expectation value of the Hamiltonian operators in a Gaussian wave packet. The question arises as to whether the energies of excited states can also be obtained by calculating an optimized expectation value between excited oscillator wave functions. If the potential shape has only a rough similarity with that of a harmonic oscillator, when there are no multiple minima, the answer is positive. Consider again the anharmonic oscillator with the action

$$\mathcal{A}[x] = \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} (\dot{x}^2 + \omega^2 x^2) + \frac{1}{4} g x^4 \right]. \quad (5.151)$$

As for the ground state, we replace the action \mathcal{A} by $\mathcal{A}_\Omega^{x_0} + \mathcal{A}_{\text{int}}^{x_0}$ with the trial oscillator action centered around the arbitrary point x_0

$$\mathcal{A}_\Omega^{x_0} = \int_0^{\hbar\beta} d\tau M \left[\frac{1}{2} \dot{x}^2 + \frac{\Omega^2}{2} (x - x_0)^2 \right], \quad (5.152)$$

and a remainder

$$\mathcal{A}_{\text{int}}^{x_0} = \int_0^\beta d\tau \left[M \frac{\omega^2 - \Omega^2}{2} (x - x_0)^2 + \frac{g}{4} x^4 \right] \quad (5.153)$$

to be treated as an interaction. Let $\psi_\Omega^{(n)}(x - x_0)$ be the wave functions of the trial oscillator.¹ With these, we form the projections

$$\begin{aligned} Z_\Omega^{(n)}(x_0) &\equiv \int dx_b dx_a \psi_\Omega^{(n)*}(x_b) (x_b \tau_b | x_a \tau_a) \psi_\Omega^{(n)}(x_a) \\ &= \int dx_b dx_a \psi_\Omega^{(n)*}(x_b) \left(\int_{(x_a, 0) \sim (x_b, \hbar\beta)} \mathcal{D}x e^{-\mathcal{A}/\hbar} \right) \psi_\Omega^{(n)}(x_a). \end{aligned} \quad (5.154)$$

If the temperature tends to zero, an optimization in the parameters x_0 and $\Omega(x_0)$ should yield information on the energy $E^{(n)}$ of this state by containing an exponentially decreasing function

$$Z^{(n)} \approx e^{-\beta E^{(n)}}. \quad (5.155)$$

Since the trial wave functions $\psi_\Omega^{(n)}(x - x_0)$ are not the true ones, the behavior (5.155) contains an admixture of Boltzmann factors $e^{-\beta E^{(n')}}$ with $n' \neq n$, which have to be eliminated. They are easily recognized by the powers of g which they carry.

The calculation of (5.154) is done in the same approximation that rendered good results for the ground state, i.e., we approximate the part of $Z^{(n)}$ behaving like (5.155) as follows:

$$Z^{(n)} \approx Z_\Omega^{(n)} e^{-\langle \mathcal{A}_{\text{int}}^{x_0} / \hbar \rangle_\Omega^{(n)}}, \quad (5.156)$$

¹In contrast to the earlier notation, we now use superscripts in parentheses to indicate the principal quantum numbers. The subscripts specify the level of approximation.

where $Z_{\Omega}^{(n)}$ denotes the contribution of the n th excited state to the oscillator partition function

$$Z_{\Omega}^{(n)} = e^{-\beta\hbar\Omega(n+1/2)}, \quad (5.157)$$

and $\langle \mathcal{A}_{\text{int}}^{x_0}/\hbar \rangle_{\Omega}^{(n)}$ stands for the expectation of $\mathcal{A}_{\text{int}}^{x_0}/\hbar$ in the state $\psi_{\Omega}^{(n)}(x - x_0)$. This approximation corresponds precisely to the first term in the perturbation expansion (3.509) (after continuing to imaginary times). ref(3.509)

Note that the approximation on the right-hand side of (5.156) is not necessarily smaller than the left-hand side, as in the Jensen-Peierls inequality (5.10), since the measure of integration in (5.154) is no longer positive. lab(x3.203)
est(3.209)

For the action (5.151), the best value of x_0 lies at the coordinate origin. This simplifies the calculation of the expectation $\langle \mathcal{A}_{\text{int}}^{x_0}/\hbar \rangle_{\Omega}^{(n)}$. The expectation of x^{2k} in the state $\psi_{\Omega}^{(n)}(x)$ is given by

$$\langle x^{2k} \rangle_{\Omega}^{(n)} = \frac{\hbar^k}{(M\Omega)^k} n_{2k}, \quad (5.158)$$

where

$$\begin{aligned} n_2 &= (n + 1/2), \quad n_4 = \frac{3}{2}(n^2 + n + 1/2), \quad n_6 = \frac{5}{4}(2n^3 + 3n^2 + 4n + 3/2), \\ n_8 &= \frac{1}{16}(70n^4 + 140n^3 + 344n^2 + 280n + 105), \quad \dots \end{aligned} \quad (5.159)$$

After inserting (5.153) into (5.156), the expectations (5.158) yield the approximation

$$Z^{(n)} \approx \exp \left\{ -\beta \left[\frac{1}{2} (\Omega^2 + \omega^2) \frac{\hbar n_2}{\Omega} + \frac{g}{4} \frac{\hbar^2 n_4}{M^2 \Omega^2} \right] \right\}. \quad (5.160)$$

With the dimensionless coupling constant $g' \equiv g\hbar/M^2\omega^3$, this corresponds to the variational energies

$$W^{(n)} = \hbar \left[\frac{1}{2} \left(\Omega + \frac{\omega^2}{\Omega} \right) n_2 + \frac{g'}{4} \frac{\omega^3}{\Omega^2} n_4 \right]. \quad (5.161)$$

They are optimized by the extremal Ω -values

$$\Omega = \Omega_1^{(n)} = \begin{cases} \frac{2}{\sqrt{3}}\omega \cosh \left[\frac{1}{3} \operatorname{arcosh} (g/g^{(n)}) \right] & \text{for } g > g^{(n)}, \\ \frac{2}{\sqrt{3}}\omega \cos \left[\frac{1}{3} \arccos (g/g^{(n)}) \right] & \text{for } g < g^{(n)}, \end{cases} \quad (5.162)$$

where

$$g^{(n)} \equiv \frac{2}{3\sqrt{3}} \frac{n_2}{n_4} \frac{M^2 \omega^3}{\hbar}. \quad (5.163)$$

The optimized $W^{(n)}$ yield the desired approximations $E_{\text{app}}^{(n)}$ for the excited energies of the anharmonic oscillator.

For large g , the trial frequency grows like

$$\Omega^{(n)} \equiv 6^{1/3} \left(\frac{g\hbar}{4M^2\omega^3} \right)^{1/3} \tilde{n}, \quad (5.164)$$

where

$$\tilde{n} \equiv \frac{4n_4/3}{2n_2} = \frac{n^2 + n + 1/2}{n + 1/2}, \quad (5.165)$$

making the energy $E_{\text{app}}^{(n)}$ grow like

$$E_{\text{BS}}^{(n)} \rightarrow \hbar\omega\kappa^{(n)} \left(\frac{g\hbar}{4M^2\omega^3} \right)^{1/3}, \quad \text{for large } g, \quad (5.166)$$

with

$$\kappa^{(n)} = \frac{3 \cdot 6^{1/3}}{8} (2n + 1) \tilde{n}^{1/3} \approx 0.68142 \times (2n + 1) \tilde{n}^{1/3}. \quad (5.167)$$

For $n = 0$, this is in good agreement with the precise growth behavior to be calculated in Section 5.16 where we shall find $\kappa_{\text{ex}}^{(0)} = 0.667\,986\dots$ (see Table 5.9).

In the limit of large g and n , this can be compared with the exact behavior obtained from the semiclassical approximation of Bohr and Sommerfeld, which gives the same leading powers in g and n as in (5.166), but a 3% larger prefactor $0.688\,253\,702 \times 2$ [recall (4.36)]. The exact values of $E^{(n)}/(g\hbar/4M^2)$ and $\frac{1}{2}\kappa^{(n)}/(n + 1/2)^{4/3}$ are for $n = 0, 2, 4, 6, 8, 10$ are shown in Table 5.4.

A comparison of the approximate energies $E_{\text{app}}^{(n)}$ with the precise numerical solutions of the Schrödinger equation in natural units $\hbar = 1$, $M = 1$ in Table 5.5 shows an excellent agreement for all coupling strengths.

Near the strong-coupling limit, the optimal frequencies $\Omega_1^{(n)}$ and the approximate energies $E_1^{(n)}$ behave as follows [in natural units; compare (5.76) and (5.77)]:

$$\begin{aligned} \Omega_1^{(n)} &= 6^{1/3} \left(\frac{\tilde{n}g}{4} \right)^{1/3} \left[1 + \frac{1}{9} \left(\frac{3}{4} \right)^{1/3} \frac{1}{(\tilde{n}g/4)^{2/3}} + \dots \right], \\ E_1^{(n)} &= \left(\frac{3}{4} \right)^{4/3} (2n + 1) \left(\frac{\tilde{n}g}{4} \right)^{1/3} \left[1 + \frac{6^{1/3}}{9} \frac{1}{(\tilde{n}g/4)^{2/3}} + \dots \right]. \end{aligned} \quad (5.168)$$

Table 5.4 Approach of variational energies of n th excited state to Bohr-Sommerfeld approximation with increasing n . Values in the last column converge rapidly towards the Bohr-Sommerfeld value $0.688\,253\,702\dots$ in Eq. (4.36).

The tabulated energies can be used to calculate an approximate partition function at all temperatures:

$$Z \approx \sum_{n=0}^{\infty} e^{-\beta E_{\text{app}}^{(n)}}. \quad (5.169)$$

The resulting free energies $F_1' = -\log Z/\beta$ agree well with the previous variational results of the Feynman-Kleinert approximation — in the plots of Fig. 5.2, the curves are indistinguishable. This is not astonishing since both approximations are dominated near zero temperature by the same optimal energy $E_{\text{app}}^{(0)}$, while approaching the semiclassical behavior at high temperatures. The previous free energy F_1 does so exactly, the free energy F_1' to a very good approximation.

By combining the Boltzmann factors with the oscillator wave functions $\psi_\Omega^{(n)}(x)$, we also calculate the density matrix $(x_b\tau_b|x_a\tau_a)$ and the distribution functions $\rho(x) = (x|\hbar\beta|x_0)$ in this approximation:

$$(x_b\tau_b|x_a\tau_a) \approx \sum_{n=0}^{\infty} \psi^{(n)}(x_b)\psi^{(n)*}(x_a)e^{-\beta E_{\text{app}}^{(n)}}. \quad (5.170)$$

They are in general less accurate than the earlier calculated particle density $\rho_1(x_0)$ of (5.94).

5.13 Systematic Improvement of Feynman-Kleinert Approximation. Variational Perturbation Theory

A systematic improvement of the variational approach leads to a convergent *variational perturbation expansion* for the effective classical potential of a quantum-mechanical system [27]. To derive it, we expand the action in powers of the deviations of the path from its average $x_0 = \bar{x}$:

$$\delta x(\tau) \equiv x(\tau) - x_0. \quad (5.171)$$

The expansion reads

$$\mathcal{A} = V(x_0) + \mathcal{A}_\Omega^{x_0} + \mathcal{A}'_{\text{int}}{}^{x_0}, \quad (5.172)$$

where $\mathcal{A}_\Omega^{x_0}$ is the quadratic action of the deviations $\delta x(\tau)$

$$\mathcal{A}_\Omega^{x_0} = \int_0^{\hbar/k_B T} d\tau \frac{M}{2} \left\{ [\delta \dot{x}(\tau)]^2 + \Omega^2(x_0)[\delta x(\tau)]^2 \right\}, \quad (5.173)$$

and $\mathcal{A}'_{\text{int}}{}^{x_0}$ contains all higher powers in $\delta x(\tau)$:

$$\mathcal{A}'_{\text{int}}{}^{x_0} = \int_0^{\hbar\beta} d\tau \left\{ \frac{g_2}{2!} [\delta x(\tau)]^2 + \frac{g_3}{3!} [\delta x(\tau)]^3 + \frac{g_4}{4!} [\delta x(\tau)]^4 + \dots \right\}. \quad (5.174)$$

The coupling constants are, in general, x_0 -dependent:

$$g_i(x_0) = V^{(i)}(x_0) - \Omega^2 \delta_{i2}, \quad V^{(i)}(x_0) \equiv \frac{d^i V(x_0)}{dx_0^i}. \quad (5.175)$$

For the anharmonic oscillator, they take the values

$$\begin{aligned} g_2(x_0) &= M[\omega^2 - \Omega^2(x_0)] + 3gx_0^2, \\ g_3(x_0) &= 6gx_0, \\ g_4(x_0) &= 6g. \end{aligned} \quad (5.176)$$

Introducing the parameter

$$r^2 = 2M(\omega^2 - \Omega^2)/g, \quad (5.177)$$

which has the dimension length square, we write $g_2(x_0)$ as

$$g_2(x_0) = g(r^2/2 + 3x_0^2). \quad (5.178)$$

With the decomposition (5.172), the Feynman-Kleinert approximation (5.32) to the effective classical potential can be written as

$$W_1^\Omega(x_0) = V(x_0) + F_\Omega^{x_0} + \frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0}. \quad (5.179)$$

To generalize this, we replace the local free energy $F_\Omega^{x_0}$ by $F_\Omega^{x_0} + \Delta F^{x_0}$, where ΔF^{x_0} denotes the local analog of the cumulant expansion (3.487). This leads to the variational perturbation expansion for the effective classical potential

$$\begin{aligned} V^{\text{eff cl}}(x_0) &= V(x_0) + F_\Omega^{x_0} + \frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0} \\ &\quad - \frac{1}{2!\hbar^2\beta} \langle \mathcal{A}_{\text{int}}^{x_0 2} \rangle_{\Omega,c}^{x_0} + \frac{1}{3!\hbar^3\beta} \langle \mathcal{A}_{\text{int}}^{x_0 3} \rangle_{\Omega,c}^{x_0} + \dots \end{aligned} \quad (5.180)$$

in terms of the connected expectation values of powers of the interaction:

$$\langle \mathcal{A}_{\text{int}}^{x_0 2} \rangle_{\Omega,c}^{x_0} \equiv \langle \mathcal{A}_{\text{int}}^{x_0 2} \rangle_\Omega^{x_0} - \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0 2}, \quad (5.181)$$

$$\langle \mathcal{A}_{\text{int}}^{x_0 3} \rangle_{\Omega,c}^{x_0} \equiv \langle \mathcal{A}_{\text{int}}^{x_0 3} \rangle_\Omega^{x_0} - 3 \langle \mathcal{A}_{\text{int}}^{x_0 2} \rangle_\Omega^{x_0} \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0} + 2 \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0 3}, \quad (5.182)$$

\vdots

By construction, the infinite sum (5.180) is independent of the choice of the trial frequency $\Omega(x_0)$.

When truncating (5.180) after the N th order, we obtain the approximation $W_N^\Omega(x_0)$ to the effective classical potential $V^{\text{eff cl}}(x_0)$. In many applications, it is sufficient to work with the third-order approximation

$$\begin{aligned} W_3^\Omega(x_0) &= V(x_0) + F_\Omega^{x_0} + \frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int}}^{x_0} \rangle_\Omega^{x_0} \\ &\quad - \frac{1}{2\hbar^2\beta} \langle \mathcal{A}_{\text{int}}^{x_0 2} \rangle_{\Omega,c}^{x_0} + \frac{1}{6\hbar^3\beta} \langle \mathcal{A}_{\text{int}}^{x_0 3} \rangle_{\Omega,c}^{x_0}. \end{aligned} \quad (5.183)$$

In contrast to (5.180), the truncated sums $W_N(x_0)$ *do* depend on $\Omega(x_0)$. Since the infinite sum is $\Omega(x_0)$ -independent, the best truncated sum $W_N(x_0)$ should lie at the frequency $\Omega_N(x_0)$ where $W_N^\Omega(x_0)$ depends minimally on it. The optimal $\Omega_N(x_0)$ is called the *frequency of least dependence*. Thus we require for (5.183)

$$\frac{\partial W_3^\Omega(x_0)}{\partial \Omega(x_0)} = 0. \quad (5.184)$$

At the frequency $\Omega_3(x_0)$ fixed by this condition, Eq. (5.183) yields the desired third-order approximation $W_3(x_0)$ to the effective classical potential.

The explicit calculation of the expectation values on the right-hand side of (5.183) proceeds according to the rules of Section 3.18. We have to evaluate the Feynman integrals associated with all vacuum diagrams. These are composed of p -particle vertices carrying the coupling constant $g_p/p!\hbar$, and of lines representing the correlation function of the fluctuations introduced in (5.23):

$$\begin{aligned}\langle \delta x(\tau) \delta x(\tau') \rangle_{\Omega}^{x_0} &= \frac{\hbar}{M} G'_{\Omega}{}^{x_0}(\tau - \tau') \\ &= a^2(\tau - \tau', x_0).\end{aligned}\quad (5.185)$$

Since this correlation function contains no zero frequency, diagrams of the type shown in Fig. 5.13 do not contribute. Their characteristic property is to fall apart when cutting a single line. They are called *one-particle reducible diagrams*. A vacuum subdiagram connected with the remainder by a single line is called a *tadpole diagram*, alluding to its biological shape. Tadpole diagrams do not contribute to the variational perturbation expansion since they vanish as a consequence of energy conservation: the connecting line ending in the vacuum, must have a vanishing frequency where the spectral representation of the correlation function $\langle \delta x(\tau) \delta x(\tau') \rangle_{\Omega}^{x_0}$ has no support, by construction.

The number of Feynman diagrams to be evaluated is reduced by ignoring at first all diagrams containing the vertices g_2 . The omitted diagrams can be recovered from the diagrams without g_2 -vertices by calculating the latter at the initial frequency ω , and by replacing ω by a modified local trial frequency,

$$\omega \rightarrow \tilde{\Omega}(x_0) \equiv \sqrt{\Omega^2(x_0) + g_2(x_0)/M}.\quad (5.186)$$

After this replacement, which will be referred to as the *square-root trick*, all diagrams are re-expanded in powers of g [remembering that $g_2(x_0)$ is by (5.178) proportional to g] up to the maximal power g^3 .

5.14 Applications of Variational Perturbation Expansion

The third-order approximation $W_3(x_0)$ is far more accurate than $W_1(x_0)$. This will now be illustrated by performing the variational perturbation expansion for the an-

Figure 5.13 Structure of a one-particle reducible vacuum diagram. The dashed box encloses a so-called tadpole diagram. Such diagrams vanish in the present expansion since an ending line cannot carry any energy and since the correlation function $\langle \delta x(\tau) \delta x(\tau') \rangle$ contains no zero frequency.

harmonic oscillator and the double-well potential. The reason for the great increase in accuracy will become clear in Section 5.15, where we shall demonstrate that this expansion *converges* rapidly towards the exact result at *all* coupling strengths, in contrast to ordinary perturbation expansions which diverges even for arbitrarily small values of g .

5.14.1 Anharmonic Oscillator at $T = 0$

Consider first the case of zero temperature, where the calculation is simplest and the approximation should be the worst. At $T = 0$, only the point $x_0 = 0$ contributes, and $\delta x(\tau)$ coincides with the path itself $\equiv x(\tau)$. Thus we may omit the superscript x_0 in all equations, so that the interaction in (5.182) becomes writing it as

$$\mathcal{A}_{\text{int}} = \frac{g}{4} \int_0^{\hbar\beta} d\tau (r^2 x^2 + x^4). \quad (5.187)$$

The effect of the r^2 -term is found by replacing the frequency ω in the original perturbation expansion for the anharmonic oscillator according to the square-root trick (5.186), which for $x_0 = 0$ is simply

$$\omega \rightarrow \tilde{\Omega} \equiv \sqrt{\Omega^2 + (\omega^2 - \Omega^2)} = \sqrt{\Omega^2 + gr^2/2M}. \quad (5.188)$$

After this replacement, all terms are re-expanded in powers of g . Finally, r^2 is again replaced by

$$r^2 \rightarrow \frac{2M}{g}(\omega^2 - \Omega^2). \quad (5.189)$$

Since the interaction is even in x , the zero-temperature expansion is automatically free of tadpole diagrams.

The perturbation expansion to third order was given in Eq. (3.554). With the above replacement it leads to the free energy

$$F = \frac{\hbar\tilde{\Omega}}{2} + \frac{g}{4} 3a^4 + \left(\frac{g}{4}\right)^2 42a^8 \frac{1}{\hbar\tilde{\Omega}} + \left(\frac{g}{4}\right)^3 4 \cdot 333a^{12} \left(\frac{1}{\hbar\tilde{\Omega}}\right)^2, \quad (5.190)$$

with

$$a^2 = \frac{\hbar}{2M\tilde{\Omega}}. \quad (5.191)$$

The higher orders can most easily be calculated with the help of the Bender-Wu recursion relations derived in Appendix 3C.²

By expanding F in powers of g up to g^3 we obtain

$$W_3^\Omega = \frac{\hbar\Omega}{2} + g(3a^4 - r^2 a^2)/4 - g^2(21a^8/8 + 3a^6 r^2/4 + a^4 r^4/16)/\hbar\Omega + g^3(333a^{12}/16 + 105a^{10} r^2/16 + 3a^8 r^4/4 + a^6 r^6/32)/(\hbar\Omega)^2. \quad (5.192)$$

After the replacement (5.189), we minimize W_3 in Ω , and obtain the third-order

²The Mathematica program is available on the internet under <http://www.physik.fu-berlin.de/~kleinert/294/programs>.

Figure 5.14 Typical Ω -dependence of approximations $W_{1,2,3}$ at $T = 0$. The coupling constant has the value $g = 0.4$. The second-order approximation W_2^Ω has no extremum. Here the minimal Ω -dependence lies at the turning point, and the condition $\partial^2 W_2^\Omega / \partial \Omega^2$ renders the best approximation to the energy (short dashes).

approximation $E_3^{(0)}(g)$ to the ground state energy. Its accuracy at various coupling strengths is seen in Table 5.6 where it is compared with the exact values obtained from numerical solutions of the Schrödinger equation. The improvement with respect

to the earlier approximation W_1 is roughly a factor 50. The maximal error is now smaller than 0.05%.

We shall see in the last subsection that up to rather high orders N , the minimum happens to be unique.

Observe that when truncating the expansion (5.183) after the second order and working with the approximation $W_2^\Omega(x_0)$, there exists no minimum in Ω , as can be seen in Fig. 5.14. The reason for this is the alternating sign of the cumulants in (5.183). This gives an alternating sign to the highest power a and thus to the highest power of $1/\Omega$ in the g^n -terms of Eq. (5.192), causing the trial energy of order N to diverge for $\Omega \rightarrow 0$ like $(-1)^{N-1}g^N \times (1/\Omega)^{3N-1}$. Since the trial energy goes for large Ω to positive infinity, only the odd approximations are guaranteed to possess a minimum.

The second-order approximation W_2 can nevertheless be used to find an improved energy value. As shown by Fig. 5.14, the frequency of least dependence Ω_2 is well defined. It is the frequency where the Ω -dependence of W_2 has its minimal absolute value. Thus we optimize Ω with the condition

$$\frac{\partial^2 W_2^\Omega}{\partial \Omega^2} = 0. \tag{5.193}$$

This leads to the energy values $E_2^{(0)}(g)$ listed in Table 5.6. They are more accurate than the values $E_1^{(0)}(g)$ by an order of magnitude.

5.14.2 Anharmonic Oscillator for $T > 0$

Consider now the anharmonic oscillator at a finite temperature, where the expansion (5.183) consists of the sum of one-particle irreducible vacuum diagrams

$$\begin{aligned}
 W_3^{\tilde{\Omega}} = \frac{1}{\beta} \left\{ -\frac{1}{2} \tilde{\Omega} \text{ (circle)} + \frac{\tilde{\Omega}^2}{3} \text{ (two circles)} \right. \\
 -\frac{1}{2!} \left(\frac{\tilde{\Omega}^3}{72} \text{ (three circles)} + \frac{\tilde{\Omega}^3}{24} \text{ (circle with two internal lines)} + \frac{\tilde{\Omega}^3}{6} \text{ (circle with one internal line)} \right) \\
 \left. + \frac{1}{3!} \left(\frac{\tilde{\Omega}^4}{2592} \text{ (four circles)} + \frac{\tilde{\Omega}^4}{1728} \text{ (circle with three external lines)} + \frac{\tilde{\Omega}^4}{3456} \text{ (circle with two internal lines and one external line)} \right. \right. \\
 \left. \left. + \frac{\tilde{\Omega}^4}{1728} \text{ (circle with one internal line and two external lines)} + \frac{\tilde{\Omega}^4}{648} \text{ (circle with one internal line and one external line)} + \frac{\tilde{\Omega}^4}{648} \text{ (circle with two internal lines)} \right) \right\}. \tag{5.194}
 \end{aligned}$$

The vertices represent the couplings $g_3(x_0)/3!\hbar$, $g_4(x_0)/4!\hbar$, whereas the lines stand for the correlation function $G'^{x_0}_\Omega(\tau, \tau')$. The numbers under each diagram are their multiplicities acting as factors.

Only the five integrals associated with the diagrams

need to be evaluated explicitly; all others arise by the expansion of $\tilde{\Omega}$ or by factorization. The explicit form of three of these integrals can be found in the first, fourth, and sixth of Eqs. (3.550). The results of the integrations are listed in Appendix 5A.

Only the second and fourth diagrams are new since they involve vertices with three legs. They can be found in Eqs. (3D.7) and (3D.8).

In quantum field theory one usually calculates Feynman integrals in momentum space. At finite temperatures, this requires the evaluation of multiple sums over Matsubara frequencies. The present quantum-mechanical example corresponds to a $D = 1$ -dimensional quantum field theory. Here it is more convenient to evaluate the integrals in τ -space. The diagrams

for example, are found by performing the integrals

$$\begin{aligned} \hbar\beta a^2 &\equiv \int_0^{\hbar\beta} d\tau G^2(\tau, \tau), \\ \hbar\beta \left(\frac{1}{\omega}\right)^2 a_3^{12} &\equiv \int_0^{\hbar\beta} \int_0^{\hbar\beta} \int_0^{\hbar\beta} G^2(\tau_1, \tau_2) G^2(\tau_2, \tau_3) G^2(\tau_3, \tau_1) d\tau_1 d\tau_2 d\tau_3. \end{aligned}$$

The factor $\hbar\beta$ on the left-hand side is due to an overall τ -integral and reflects the temporal translation symmetry of the system; the factors $1/\omega$ arise from the remaining τ -integrations whose range is limited by the correlation time $1/\omega$.

In general, the β - and x_0 -dependent parameters a_V^{2L} have the dimension of a length to the n th power and the associated diagrams consist of m vertices and $n/2$ lines (defining $a_1^2 \equiv a^2$).

We now use the rule (5.188) to replace ω by $\tilde{\Omega}$ and expand everything in powers of g_2 up to the third order. The expansion can be performed diagrammatically in each Feynman diagram. Letting a dot on a line indicate the coupling $g_2/2\hbar$, the one-loop diagram is expanded as follows:

$$\tilde{\Omega} \text{ (circle with dot) } = \text{ (circle) } - 2 \text{ (circle with dot) } + \text{ (circle with two dots) } - \frac{1}{3} \text{ (circle with three dots) } . \tag{5.195}$$

The other diagrams are expanded likewise:

$$\begin{aligned} \tilde{\tilde{\Omega}} \text{ (figure-eight) } &= \text{ (figure-eight) } - \text{ (figure-eight with dot) } + \frac{1}{6} \text{ (figure-eight with two dots) } + \frac{1}{6} \text{ (figure-eight with three dots) } , \\ \frac{1}{2} \tilde{\tilde{\Omega}} \text{ (horizontal oval) } &= \frac{1}{2} \text{ (horizontal oval) } - \frac{1}{6} \text{ (horizontal oval with dot) } , \\ \frac{1}{2} \tilde{\tilde{\Omega}} \text{ (vertical oval) } &= \frac{1}{2} \text{ (vertical oval) } - \frac{1}{6} \text{ (vertical oval with dot) } , \end{aligned}$$

$$\frac{1}{2} \text{diag}_{\tilde{\Omega}} = \frac{1}{2} \text{diag}_1 - \frac{1}{6} \text{diag}_2 - \frac{1}{6} \text{diag}_3 .$$

In this way, we obtain from (5.194) the complete graphical expansion for $W_3^\Omega(x_0)$ including all vertices associated with the coupling $g_2(x_0)$:

$$\begin{aligned} \beta W_3^\Omega(x_0) = & -\frac{1}{2} \text{diag}_0 + \left(\frac{1}{2} \text{diag}_1 + \frac{1}{8} \text{diag}_2 \right) \\ & - \frac{1}{2!} \left[\frac{1}{2} \text{diag}_3 + \frac{1}{2} \text{diag}_4 + \frac{1}{8} \text{diag}_5 + \frac{1}{24} \text{diag}_6 + \frac{1}{6} \text{diag}_7 \right] \\ & + \frac{1}{3!} \left[\text{diag}_8 + 3 \left(\frac{1}{4} \text{diag}_9 + \frac{1}{2} \text{diag}_{10} \right) \right. \\ & + 3 \left(\frac{1}{4} \text{diag}_{11} + \frac{1}{4} \text{diag}_{12} + \frac{1}{6} \text{diag}_{13} + \frac{1}{2} \text{diag}_{14} \right) \\ & + \left(\frac{3}{16} \text{diag}_{15} + \frac{1}{8} \text{diag}_{16} + \frac{1}{4} \text{diag}_{17} + \frac{1}{8} \text{diag}_{18} \right. \\ & \left. \left. + \frac{3}{4} \text{diag}_{19} + \frac{3}{4} \text{diag}_{20} \right) \right]. \end{aligned} \quad (5.196)$$

In the latter diagrams, the vertices represent directly the couplings g_n/\hbar . The denominators $n!$ of the previous vertices $g_n/n!\hbar$ have been combined with the multiplicities of the diagrams yielding the indicated prefactors. The corresponding analytic expression for $W_3^\Omega(x_0)$ is

$$\begin{aligned} W_3^\Omega(x_0) = & V(x_0) + F_\Omega^{x_0} + \left(\frac{g_2}{2} a^2 + \frac{g_4}{8} a^4 \right) \\ & - \frac{1}{2! \hbar \Omega} \left[\frac{g_2^2}{2} a_2^4 + \frac{g_2 g_4}{2} a_2^4 a^2 + \frac{g_4^2}{8} a_2^4 a^4 + \frac{g_4^2}{24} a_2^8 + \frac{g_3^2}{6} a_2^6 \right] \\ & + \frac{1}{3! \hbar^2 \Omega^2} \left[g_2^3 a_3^6 + 3 \left(\frac{g_2^2 g_4}{4} (a_2^4)^2 + \frac{g_2^2 g_4}{2} a_3^6 a^2 \right) \right. \\ & \quad \left. + 3 \left(\frac{g_2 g_4^2}{4} (a_2^4)^2 a^2 + \frac{g_2 g_4^2}{4} a_3^6 a^4 + \frac{g_2 g_4^2}{6} a_3^{10} + \frac{g_2 g_3^2}{2} a_3^8 \right) \right. \\ & \left. + \left(\frac{3 g_4^3}{16} (a_2^4 a^2)^2 + \frac{g_4^3}{8} a_3^6 a^6 + \frac{g_4^3}{4} a_3^{10} a^2 + \frac{g_4^3}{8} a_3^{12} + \frac{3 g_3^2 g_4}{4} a_3^{10} + \frac{3 g_3^2 g_4}{4} a_3^8 a^2 \right) \right]. \end{aligned} \quad (5.197)$$

The quantities a_V^{2L} are ordered in the same way as the associated diagrams in (5.196). As before, we have omitted the variable x_0 in all but the first three terms, for brevity.

The optimal trial frequency $\Omega(x_0)$ is found numerically by searching, at each value of x_0 , for the real roots of the first derivate of $W_3^\Omega(x_0)$ with respect to $\Omega(x_0)$. Just as for zero temperature, the solution happens to be unique.

By calculating the integral

$$Z_3 = \int_{-\infty}^{\infty} \frac{dx_0}{l_e(\hbar\beta)} e^{-W_3(x_0)/k_B T}, \quad (5.198)$$

we obtain the approximate free energy

$$F_3 = -\frac{1}{\beta} \ln Z_3. \quad (5.199)$$

The results are listed in Table 5.7 for various coupling constants g and temperatures. They are compared with the exact free energy

$$F_{\text{ex}} = -\frac{1}{\beta} \log \sum_n \exp(-\beta E_n), \quad (5.200)$$

whose energies E_n were obtained by numerically solving the Schrödinger equation.

Table 5.7 Free energy of anharmonic oscillator with potential $V(x) = x^2/2 + gx^4/4$ for various coupling strengths g and $\beta = 1/kT$.

We see that to third order, the new approximation yields energies which are better than those of F_1 by a factor of 30 to 50. The remaining difference with respect to the exact energies lies in the fourth digit.

In the high-temperature limit, all approximations $W_N(x_0)$ tend to the classical result $V(x_0)$, as they should. Thus, for small β , the approximations $W_3(x_0)$ and $W_1(x_0)$ are practically indistinguishable.

The accuracy is worst at zero temperature. Using the $T \rightarrow 0$ -limits of the Feynman integrals a_V^{2L} given in (3.553) and (3D.14), the approximation W_3^Ω takes the simple form

$$\begin{aligned} W_3^\Omega(x_0) = & V(x_0) + \frac{\hbar\Omega(x_0)}{2} + \frac{g_2}{2}a^2 + \frac{g_4}{8}a^4 \\ & - \frac{1}{2\hbar\Omega} \left[\frac{g_2^2}{2}a^4 + \frac{g_2g_4}{2}a^6 + \frac{g_3^2}{6}\frac{2}{3}a^6 + \frac{g_4^2}{24}\frac{7}{2}a^8 \right] \\ & + \frac{1}{6\hbar^2\Omega^2} \left[g_2^3\frac{3}{2}a^6 + g_2g_3^2\frac{4}{3}a^8 + g_2^2g_43a^8 + g_3^2g_4\frac{13}{3}a^{10} + g_2g_4^2\frac{35}{16}a^{10} + g_4^3\frac{37}{64}a^{12} \right], \end{aligned} \quad (5.201)$$

where $a^2 = \hbar/2M\Omega$. As in (5.197), we have omitted the arguments x_0 in Ω and g_i , for brevity. At zero temperature, the remaining integral over x_0 in the partition function (5.198) receives its only contribution from the point $x_0 = 0$, where $W_3(0)$ is minimal. There it reduces to the energy W_3 of Eq. (5.192).

5.15 Convergence of Variational Perturbation Expansion

For a single interaction x^p , the approximation W_N at zero temperature can easily be carried to high orders [13, 14]. The perturbation coefficients are available exactly from recursion relations, which were derived for the anharmonic oscillator with $p = 4$ in Appendix 3C. The starting point is the ordinary perturbation expansion for the energy levels of the anharmonic oscillator

$$E^{(n)} = \omega \sum_{k=0}^{\infty} E_k^{(n)} \left(\frac{g}{4\omega^3} \right)^k. \quad (5.202)$$

It was remarked in (3C.27) and will be proved in Section 17.10 [see Eq. (17.323)] that the coefficients $E_k^{(n)}$ grow for large k like

$$E_k^{(n)} \longrightarrow -\frac{1}{\pi} \sqrt{\frac{6}{\pi}} \frac{12^n}{n!} (-3)^k \Gamma(k+n+1/2). \quad (5.203)$$

Using Stirling's formula³

$$n! \approx (2\pi)^{1/2} n^{n-1/2} e^{-n}, \quad (5.204)$$

this amounts to

$$E_k^{(n)} \longrightarrow -\frac{2\sqrt{3}}{\pi} \frac{(-4)^n}{n!} \left[\frac{-3(k+n)}{e} \right]^{n+k}. \quad (5.205)$$

Thus, $E_k^{(n)}$ grows faster than any power in k . Such a strong growth implies that the expansion has a zero radius of convergence. It is a manifestation of the fact that the energy possesses an essential singularity in the complex g -plane at the expansion point $g = 0$. The series is a so-called asymptotic series. The precise form of the

³M. Abramowitz and I. Stegun, op. cit., Formulas 6.1.37 and 6.1.38.

Figure 5.15 Typical Ω -dependence of N th approximations W_N at $T = 0$ for increasing orders N . The coupling constant has the value $g/4 = 0.1$. The dashed horizontal line indicates the exact energy.

singularity will be calculated in Section 17.10 with the help of the semiclassical approximation.

If we want to extract meaningful numbers from a divergent perturbation series such as (5.202), it is necessary to find a convergent resummation procedure. Such a procedure is supplied by the variational perturbation expansion, as we now demonstrate for the ground state energy of the anharmonic oscillator.

Truncating the infinite sum (5.202) after the N th term, the replacement (5.188) followed by a re-expansion in powers of g up to order N leads to the approximation W_N at zero temperature:

$$W_N^\Omega = \Omega \sum_{l=0}^N \varepsilon_l^{(0)} \left(\frac{g}{4\Omega^3} \right)^l, \quad (5.206)$$

Figure 5.16 New plateaus in W_N developing for higher orders $N \geq 15$ in addition to the minimum which now gives worse results. For $N = 11$ the new plateau is not yet extremal, but it is the proper region of least Ω -dependence yielding the best approximation to the exact energy indicated by the dashed horizontal line. The minimum has fallen far below this value and is no longer useful. The figure looks similar for all couplings (in the plot, $g = 0.4$). The reason is the scaling property (5.215) proved in Appendix 5B.

with the re-expansion coefficients

$$\varepsilon_l^{(0)} = \sum_{j=0}^l E_j^{(0)} \binom{(1-3j)/2}{l-j} (-4\sigma)^{l-j}. \quad (5.207)$$

Here σ denotes the dimensionless function of Ω

$$\sigma \equiv -\frac{1}{2} \Omega r^2 = \frac{\Omega(\Omega^2 - 1)}{g}. \quad (5.208)$$

In Fig. 5.15 we have plotted the Ω -dependence of W_N for increasing N at the coupling constant $g/4 = 0.1$. For odd and even N , an increasingly flat plateau develops at the optimal energy.

At larger orders $N \geq 15$, the initially flat plateau is deformed into a minimum with a larger curvature and is no longer a good approximation. However, a new plateau has developed yielding the best energy. This is seen on the high-resolution plot in Fig. 5.16. At $N = 11$, the new plateau is not yet extremal but close to the correct energy.

The worsening extrema in Fig. 5.16 correspond here to points leaving the optimal dashed into the upward direction. The newly forming plateaus lie always on the dashed curve.

The set of all extremal Ω_N -values for odd N up to $N = 91$ is shown in Fig. 5.17. The optimal frequencies with smallest curvature are marked by a fat dot. In Subsection 17.10.5. we shall derive that

$$\sigma_N = \frac{\Omega_N(\Omega_N^2 - 1)}{g} \quad (5.209)$$

Figure 5.17 Trial frequencies Ω_N extremizing the variational approximation W_N at $T = 0$ for odd $N \leq 91$. The coupling is $g/4 = 1$. The dashed curve corresponds to the approximation (5.211) [related to Ω_N via (5.208)]. The frequencies on this curve produce the fastest convergence. The worsening extrema in Fig. 5.16 correspond here to points leaving the optimal dashed into the upward direction. The newly forming plateaus lie always on the dashed curve.

grows for large N like

$$\sigma_N \approx cN, \quad c = 0.186047\dots, \quad (5.210)$$

so that Ω_N grows like $\Omega_N \approx (cNg)^{1/3}$. For smaller N , the best Ω_N -values in Fig. 5.17 can be fitted with the help of the corrected formula (5.210):

$$\sigma_N \approx cN \left(1 + \frac{6.85}{N^{2/3}} \right). \quad (5.211)$$

The associated Ω_N -curve is shown as a dashed line. It is the lower envelope of the extremal frequencies.

The set of extremal and turning point frequencies Ω_N is shown in Fig. 5.18 for even and odd N up to $N = 30$. The optimal extrema with smallest curvature are again marked by a fat dot. The theoretical curve for an optimal convergence calculated from (5.211) and (5.209) is again plotted as a dashed line.

In Table 5.8, we illustrate the precision reached for large orders N at various coupling constants g by a comparison with accurate energies derived from numerical solutions of the Schrödinger equation.

The approach to the exact energy values is illustrated in Fig. 5.19 which shows that a good convergence is achieved by using the lowest of all extremal frequencies, which lie roughly on the dashed theoretical curve in Fig. 5.17 and specify the position of the plateaus. The frequencies Ω_N on the higher branches leaving the dashed curve in that figure, on the other hand, do not yield converging energy values. The

Figure 5.18 Extremal and turning point frequencies Ω_N in variational approximation W_N at $T = 0$ for even and odd $N \leq 30$. The coupling is $g/4 = 1$. The dashed curve corresponds to the approximation (5.211) [related to Ω_N via (5.208)].

Figure 5.19 Difference between approximate ground state energies $E = W_N$ and exact energies E_{ex} for odd N corresponding to the Ω_N -values shown in Fig. 5.17. The coupling is $g/4 = 1$. The lower curve follows roughly the error estimate to be derived in Eq. (17.409). The extrema in Fig. (5.17) which move away from the dashed curve lie here on horizontal curves whose accuracy does not increase.

sharper minima in Fig. 5.16 correspond precisely to those branches which no longer determine the region of weakest Ω -dependence.

The anharmonic oscillator has the remarkable property that a plot of the Ω_N -values in the N, σ_N -plane is universal in the coupling strengths g ; the plots do not depend on g . To see the reason for this, we reinsert explicitly the frequency ω (which

Table 5.8 Comparison of the variational approximations W_N at $T = 0$ for increasing N with the exact ground state energy at various coupling constants g .

was earlier set equal to unity). Then the re-expanded energy W_N in Eq. (5.206) has the general scaling form

$$W_N^\Omega = \Omega w_N(\hat{g}, \hat{\omega}^2), \tag{5.212}$$

where w_N is a dimensionless function of the reduced coupling constant and frequency

$$\hat{g} \equiv \frac{g}{\Omega^3}, \quad \hat{\omega} \equiv \frac{\omega}{\Omega}, \tag{5.213}$$

respectively. When differentiating (5.212),

$$\frac{d}{d\Omega} W_N = \left[1 - 3\hat{g} \frac{d}{d\hat{g}} - 2\hat{\omega}^2 \frac{d}{d\hat{\omega}^2} \right] w_N(\hat{g}, \hat{\omega}^2), \tag{5.214}$$

we discover that the right-hand side can be written as a product of \hat{g}^N and a dimensionless polynomial of order N depending only on $\sigma = \Omega(\Omega^2 - \omega^2)/g$:

$$\frac{d}{d\Omega} W_N^\Omega = \hat{g}^N p_N(\sigma). \tag{5.215}$$

A proof of this will be given in Appendix 5B for any interaction x^p . The universal optimal σ_N -values are obtained from the zeros of $p_N(\sigma)$.

It is possible to achieve the same universality for the optimal frequencies of the even approximations W_N by determining them from the extrema of $p_N(\sigma)$ rather than from the turning points of W_N as a function of Ω .

The universal functions $p_N(\sigma)$ are found most easily by replacing the variable σ in the coefficients $\varepsilon_l^{(0)}$ of the re-expansion (5.206) by its $\omega = 0$ -limit $\sigma|_{\omega=0} = \Omega^3/g = 1/\hat{g}$. This yields the simpler expression

$$W_N^\Omega = \Omega w_N(\hat{g}, 0) = \Omega \sum_{l=0}^N \varepsilon_l^{(0)} \left(\frac{\hat{g}}{4} \right)^l, \tag{5.216}$$

with

$$\varepsilon_l^{(0)} = \sum_{j=0}^l E_j^{(0)} \binom{(1-3j)/2}{l-j} (-4/\hat{g})^{l-j}. \tag{5.217}$$

The derivative of W_N with respect to Ω yields

$$p_N(\sigma) = \hat{g}^{-N} \left[1 - 3\hat{g} \frac{d}{d\hat{g}} \right] w_N(\hat{g}, 0) \Big|_{\hat{g}=1/\sigma}. \tag{5.218}$$

In Section 17.10, we show the re-expansion coefficients $\varepsilon_k^{(0)}$ in (5.207) to be for large k proportional to $E_k^{(0)}$:

$$\varepsilon_k^{(0)} \approx e^{-2\sigma_N} E_k^{(0)}, \quad \sigma_N = \frac{\Omega_N(\Omega_N^2 - 1)}{g} \tag{5.219}$$

[see Eq. (17.396)]. Thus, at any fixed Ω , the re-expanded series has the same asymptotic growth as the original series with the same vanishing radius of convergence. The behavior (5.219) can be seen in Fig. 5.20(a) where we have plotted the logarithm of the absolute value of the k th term

$$S_k = \varepsilon_k^{(0)} \left(\frac{\hat{g}}{4} \right)^k \tag{5.220}$$

of the re-expanded perturbation series (5.202) for various optimal values Ω_N and $g = 40$. All curves show a growth $\propto k^k$. The terms in the original series start growing immediately (precocious growth). Those in the re-expanded series, on the other hand, decrease initially and go through a minimum before they start growing (retarded growth). The dashed curves indicate the analytically calculated asymptotic behavior (5.219).

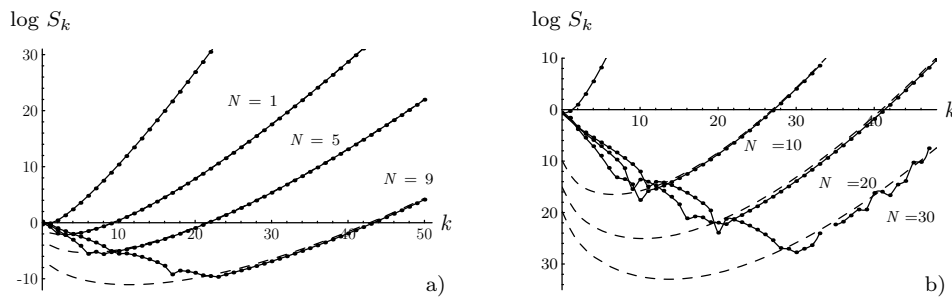

Figure 5.20 Logarithmic plot of k th terms in re-expanded perturbation series at a coupling constant $g/4 = 1$:

- (a) Frequencies Ω_N extremizing the approximation W_N . The dashed curves indicate the theoretical asymptotic behavior (5.219).
- (b) Frequencies Ω_N corresponding to the dashed curve in Fig. 5.17. The minima lie for each N precisely at $k = N$, producing the fastest convergence. The curves labeled $\Omega = \omega$ indicate the k th term in the original perturbation series.

The increasingly retarded growth is the reason why energies obtained from the variational expansion converge towards the exact result. Consider the terms S_k of the resummed series with frequencies Ω_N taken from the theoretical curve of optimal convergence in Fig. 5.17 (or 5.18). In Fig. 5.20(b) we see that the terms S_k are minimal at $k = N$, i.e., at the last term contained in the approximation W_N . In general, a divergent series yields an optimal result if it is truncated after the smallest term S_k . The size of the last term gives the order of magnitude of the error in the truncated evaluation. The re-expansion makes it possible to find, for every N , a frequency Ω_N which makes the truncation optimal in this sense.

5.16 Variational Perturbation Theory for Strong-Coupling Expansion

From the $\omega \rightarrow 0$ -limit of (5.206), we obtain directly the strong-coupling behavior of W_N . Since $\Omega = (g/\hat{g})^{1/3}$, we can write

$$W_N = (g/\hat{g})^{1/3} w_N(\hat{g}, 0), \quad (5.221)$$

and evaluate this at the optimal value $\hat{g} = 1/\sigma_N$. The large- g behavior of W_N is therefore

$$W_N \xrightarrow{g \rightarrow \infty} (g/4)^{1/3} b_0, \quad (5.222)$$

with the coefficient

$$b_0 = (4/\hat{g})^{1/3} w_N(\hat{g}, 0)|_{\hat{g}=1/\sigma_N}. \quad (5.223)$$

Figure 5.21 Logarithmic plot of N -behavior of strong-coupling expansion coefficients b_0 and b_1 .

Figure 5.22 Oscillations of approximate strong-coupling expansion coefficient b_0 as a function of N when approaching exponentially fast the exact limit. The exponential behavior has been factored out. The upper and lower points show the odd- N and even- N approximations, respectively.

The higher corrections to the leading behavior (5.222) are found just as easily. By expanding $w_N(\hat{g}, \hat{\omega}^2)$ in powers of $\hat{\omega}^2$,

$$W_N = \left(\frac{g}{\hat{g}}\right)^{1/3} \left[1 + \hat{\omega}^2 \frac{d}{d\hat{\omega}^2} + \frac{\hat{\omega}^4}{2!} \left(\frac{d}{d\hat{\omega}^2}\right)^2 + \dots \right] w_N(\hat{g}, \hat{\omega}^2) \Big|_{\hat{\omega}^2=0}, \quad (5.224)$$

and inserting

$$\hat{\omega}^2 = \frac{\hat{g}^{2/3}}{(g/\omega^3)^{2/3}}, \quad (5.225)$$

we obtain the expansion

$$W_N = \left(\frac{g}{4}\right)^{1/3} \left[b_0 + b_1 \left(\frac{g}{4\omega^3}\right)^{-2/3} + b_2 \left(\frac{g}{4\omega^3}\right)^{-4/3} + \dots \right], \quad (5.226)$$

with the coefficients

$$b_n = \frac{1}{n!} \left(\frac{\hat{g}}{4}\right)^{(2n-1)/3} \left(\frac{d}{d\hat{\omega}^2}\right)^n w_N(\hat{g}, \hat{\omega}^2) \Big|_{\hat{g}=1/\sigma_N, \hat{\omega}^2=0}. \quad (5.227)$$

The derivatives on the right-hand side have the expansions

$$\left(\frac{d}{d\hat{\omega}^2}\right)^n w_N(\hat{g}, \hat{\omega}^2) = \sum_{l=0}^N \varepsilon_{nl}^{(0)} \left(\frac{\hat{g}}{4}\right)^l, \quad (5.228)$$

Table 5.9 Coefficients b_n of strong-coupling expansion of ground state energy of anharmonic oscillator obtained from a perturbation expansion of order 251. An extremely precise value for b_0 was given by F. Vinette and J. Cizek, *J. Math. Phys.* *32*, 3392 (1991): $b_0 = 0.667\,986\,259\,155\,777\,108\,270\,962\,016\,198\,601\,994\,304\,049\,36\dots$

with the re-expansion coefficients

$$\frac{1}{n!}\varepsilon_{nl}^{(0)} = \sum_{j=0}^{l-n} E_j^{(0)} \binom{(1-3j)/2}{l-j} \binom{l-j}{n} (-1)^{l-j-n} (4/\hat{g})^{l-j}. \quad (5.229)$$

For increasing N , the coefficients b_0, b_1, \dots converge rapidly against the values shown in Table 5.9. From the logarithmic plot in Fig. 5.21 we extract a convergence

$$|b_0 - b_0^{\text{ex}}| \sim e^{8.2-9.7N^{1/3}}, \quad |b_1 - b_1^{\text{ex}}| \sim e^{6.4-9.1N^{1/3}}. \quad (5.230)$$

This behavior will be derived in Subsection 17.10.5, where we shall find that for any $g > 0$, the error decreases at large N roughly like $e^{-[9.7+(cg)^{-2/3}]N^{1/3}}$ [see Eq. (17.409)].

The approach to this limiting behavior is oscillatory, as seen in Fig. 5.22 where we have removed the exponential falloff and plotted $e^{-6.5+9.42N^{1/3}}(b_0 - b_0^{\text{ex}})$ against N [16].

For the proof of the convergence of the variational perturbation expansion in Subsection 17.10.5. it will be important to know that the strong-coupling expansion for the ground state energy

$$E^{(0)} = \left(\frac{g}{4}\right)^{1/3} \left[b_0 + b_1 \left(\frac{g}{4\omega^3}\right)^{-2/3} + b_2 \left(\frac{g}{4\omega^3}\right)^{-4/3} + \dots \right], \quad (5.231)$$

converges for large enough

$$g > g_s. \quad (5.232)$$

The same is true for the excited energies.

5.17 General Strong-Coupling Expansions

The coefficients of the strong-coupling expansion can be derived for any divergent perturbation series

$$E_N(g) = \sum_{n=0}^N a_n g^n, \quad (5.233)$$

for which we know that it behaves at large couplings g like

$$E(g) = g^{p/q} \sum_{m=0}^M b_m (g^{-2/q})^m. \quad (5.234)$$

The series (5.233) can trivially be rewritten as

$$E_N(g) = \omega^p \sum_{n=0}^N a_n \left(\frac{g}{\omega^q}\right)^n, \quad (5.235)$$

with $\omega = 1$. We now apply the square-root trick (5.188) and replace ω by the identical expression

$$\omega \equiv \sqrt{\Omega^2 + (\omega^2 - \Omega^2)}, \quad (5.236)$$

containing a dummy scaling parameter Ω . The series (5.235) is then re-expanded in powers of g up to the order N , thereby treating $\omega^2 - \Omega^2$ as a quantity of order g . The result is most conveniently expressed in terms of dimensionless parameters $\hat{g} \equiv g/\Omega^q$ and $\sigma \equiv (1 - \hat{\omega}^2)/\hat{g}$, where $\hat{\omega} \equiv \omega/\Omega$. Then the replacement (5.236) amounts to

$$\omega \longrightarrow \Omega(1 - \sigma\hat{g})^{1/2}, \quad (5.237)$$

so that the re-expanded series reads explicitly

$$W_N(\hat{g}, \sigma) = \Omega^p \sum_{n=0}^N \varepsilon_n(\sigma) (\hat{g})^n, \quad (5.238)$$

with the coefficients:

$$\varepsilon_n(\sigma) = \sum_{j=0}^n a_j \binom{(p - qj)/2}{n - j} (-\sigma)^{n-j}. \quad (5.239)$$

For any fixed g , we form the first and second derivatives of $W_N^\Omega(g)$ with respect to Ω , calculate the Ω -values of the extrema and the turning points, and select the smallest of these as the optimal scaling parameter Ω_N . The function $W_N(g) \equiv W_N(g, \Omega_N)$ constitutes the N th variational approximation $E_N(g)$ to the function $E(g)$.

We now take this approximation to the strong-coupling limit $g \rightarrow \infty$. For this we observe that (5.238) has the general scaling form

$$W_N^\Omega(g) = \Omega^p w_N(\hat{g}, \hat{\omega}^2). \tag{5.240}$$

For dimensional reasons, the optimal Ω_N increases with g for large g like $\Omega_N \approx g^{1/q} c_N$, so that $\hat{g} = c_N^{-q}$ and $\sigma = 1/\hat{g} = c_N^q$ remain finite in the strong-coupling limit, whereas $\hat{\omega}^2$ goes to zero like $1/[c_N(g/\omega^q)^{1/q}]^2$. Hence

$$W_N^{\Omega_N}(g) \approx g^{p/q} c_N^p w_N(c_N^{-q}, 0). \tag{5.241}$$

Here c_N plays the role of the variational parameter to be determined by the lowest extremum or turning point of $c_N^p w_N(c_N^{-q}, 0)$.

The full strong-coupling expansion is obtained by expanding $w_N(\hat{g}, \hat{\omega}^2)$ in powers of $\hat{\omega}^2 = (g/\omega^q \hat{g})^{-2/q}$ at a fixed \hat{g} . The result is

$$W_N(g) = g^{p/q} \left[\bar{b}_0(\hat{g}) + \bar{b}_1(\hat{g}) \left(\frac{g}{\omega^q}\right)^{-2/q} + \bar{b}_2(\hat{g}) \left(\frac{g}{\omega^q}\right)^{-4/q} + \dots \right], \tag{5.242}$$

with

$$\bar{b}_n(\hat{g}) = \frac{1}{n!} \left(\frac{d}{d\hat{\omega}^2}\right)^n w_N^{(n)}(\hat{g}, \hat{\omega}^2) \Big|_{\hat{\omega}^2=0} \hat{g}^{(2n-p)/q}, \tag{5.243}$$

with respect to $\hat{\omega}^2$. Explicitly:

$$\frac{1}{n!} w_N^{(n)}(\hat{g}, 0) = \sum_{l=0}^N (-1)^{l+n} \sum_{j=0}^{l-n} a_j \binom{(p-qj)/2}{l-j} \binom{l-j}{n} (-\hat{g})^j. \tag{5.244}$$

Since $\hat{g} = c_N^{-q}$, the coefficients $\bar{b}_n(\hat{g})$ may be written as functions of the parameter c :

$$\bar{b}_n(c) = \sum_{l=0}^N a_l \sum_{j=0}^{N-l} \binom{(p-lq)/2}{j} \binom{j}{n} (-1)^{j-n} c^{p-lq-2n}. \tag{5.245}$$

The values of c which optimize $W_N(g)$ for fixed g yield the desired values of c_N . The optimization may be performed stepwise using directly the expansion coefficients $\bar{b}_n(c)$. First we optimize the leading coefficient $b_0(c)$ as a function of c and identifying the smallest of them as c_N . Next we have to take into account that for large but finite α , the trial frequency Ω has corrections to the behavior $\hat{g}^{1/q} c$. The coefficient c will depend on \hat{g} like

$$c(\hat{g}) = c + \gamma_1 \left(\frac{\hat{g}}{\omega^q}\right)^{-2/q} + \gamma_2 \left(\frac{\hat{g}}{\omega^q}\right)^{-4/q} + \dots, \tag{5.246}$$

requiring a re-expansion of c -dependent coefficients \bar{b}_n in (5.242). The expansion coefficients c and γ_n for $n = 1, 2, \dots$ are determined by extremizing $\bar{b}_{2n}(c)$. The final result can again be written in the form (5.242) with $\bar{b}(c)_n$ replaced by the final b_n :

$$W_N(g) = g^{p/q} \left[b_0 + b_1 \left(\frac{g}{\omega^q}\right)^{-2/q} + b_2 \left(\frac{g}{\omega^q}\right)^{-4/q} + \dots \right]. \tag{5.247}$$

The final b_n are determined by the equations shown in Table 5.10. The two leading coefficients receive no correction and are omitted.

The extremal values of \hat{g} will have a strong-coupling expansion corresponding to (5.246):

$$\hat{g} = c_N^{-q} \left[1 + \delta_1 \left(\frac{g}{\omega^q}\right)^{-2/q} + \delta_2 \left(\frac{g}{\omega^q}\right)^{-4/q} + \dots \right]. \tag{5.248}$$

Table 5.10 Equations determining coefficients b_n in strong-coupling expansion (5.247) from the functions $\bar{b}_n(c)$ in (5.245) and their derivatives. For brevity, we have suppressed the argument c in the entries.

2	$b_2 + \gamma_1 b'_1 + \frac{1}{2} \gamma_1^2 b''_0$	b'_1/b''_0
3	$\bar{b}_3 + \gamma_2 \bar{b}'_1 + \gamma_1 \bar{b}'_2 + \gamma_1 \gamma_2 \bar{b}''_0 + \frac{1}{2} \gamma_1^2 \bar{b}''_1 + \frac{1}{6} \gamma_1^3 \bar{b}^{(3)}_0$	$(\bar{b}'_2 + \gamma_1 \bar{b}''_1 + \frac{1}{2} \gamma_1^2 \bar{b}^{(3)}_0)/\bar{b}''_0$
4	$\bar{b}_4 + \gamma_3 \bar{b}'_1 + \gamma_2 \bar{b}'_2 + \gamma_1 \bar{b}'_3 + (\frac{1}{2} \gamma_2^2 + \gamma_1 \gamma_3) \bar{b}''_0 + \gamma_1 \gamma_2 \bar{b}''_1 + \frac{1}{2} \gamma_1^2 \bar{b}''_2 + \frac{1}{2} \gamma_1^2 \gamma_2 \bar{b}^{(3)}_0 + \frac{1}{6} \gamma_1^3 \bar{b}^{(3)}_1 + \frac{1}{24} \gamma_1^4 \bar{b}^{(4)}_0$	$(\bar{b}'_3 + \gamma_2 \bar{b}''_1 + \gamma_1 \bar{b}''_2 + \gamma_1 \gamma_2 \bar{b}^{(3)}_0 + \frac{1}{2} \gamma_1^2 \bar{b}^{(3)}_1 + \frac{1}{6} \gamma_1^3 \bar{b}^{(4)}_0)/\bar{b}''_0$

The convergence of the general strong-coupling expansion is similar to the one observed for the anharmonic oscillator. This will be seen in Subsection 17.10.5.

The general strong-coupling expansion has important applications in the theory of critical phenomena. This theory renders expansions of the above type for the so-called critical exponents, which have to be evaluated at infinitely strong (bare) couplings of scalar field theories with $g\phi^4$ interactions. The results of these applications are better than those obtained previously with a much more involved theory based on a combination of renormalization group equations and Padé-Borel resummation techniques [28]. The critical exponents have power series expansions in powers of g/ω in the physically most interesting three-dimensional systems, where $\omega^2/2$ is the factor in front of the quadratic field term ϕ^2 . The important phenomenon observed in such systems is the appearance of *anomalous dimensions*. These imply that the expansion terms $(g/\omega)^n$ cannot simply be treated with the square-root trick (5.236). The anomalous dimension requires that $(g/\omega)^n$ must be treated as if it were $(g/\omega^q)^n$

when applying the square-root trick. Thus we must use the *anomalous square-root trick*

$$\omega \rightarrow \Omega \left[1 + \left(\frac{\omega}{\Omega} \right)^{2/q} \right]^{q/2}. \quad (5.249)$$

The power $2/q$ appearing in the strong-coupling expansion (5.234) is experimentally observable since it governs the approach of the system to the scaling limit. This exponent is usually denoted by the letter ω , and is referred to as the *Wegner exponent* [29]. This exponent ω is not to be confused with the frequency ω in the present discussion. In superfluid helium, for example, this critical exponent is very close to the value $4/5$, implying $q \approx 5/2$. The Wegner exponent of fluctuating quantum fields cannot be deduced, as in quantum mechanics, from simple scaling analyses of the action. It is, however, calculable by applying variational perturbation theory to the logarithmic derivative of the power series of the other critical exponents. These are called β -functions and have to vanish for the correct ω . This procedure is referred to as *dynamical determination* of ω and has led to values in excellent agreement with experiment [17].

In the above variational procedure, the existence of anomalous dimensions is signaled by the appearance of a nonzero slope in the plateaus of Figs. 5.14. If this happens, the power q in the replacement (5.249) must be modified until the plateaus are flat. This method is a practical alternative to determining the Wegner exponent $\omega = 2/q$ via the β -function.

5.18 Variational Interpolation between Weak and Strong-Coupling Expansions

The possibility of calculating the strong-coupling coefficients from the perturbation coefficients can be used to find a *variational interpolation* of a function with known weak- and strong-coupling coefficients [18]. Such pairs of expansions are known for many other physical systems, for example most lattice models of statistical mechanics [19]. If applied to the ground state energy of the anharmonic oscillator, this method converges exponentially fast [15]. The weak-coupling expansion of the ground state energy of the anharmonic oscillator has the form (5.233). In natural units with $\hbar = M = \omega = 1$, the lowest coefficient a_0 is trivially determined to be $a_0 = 1/2$ by the ground state energy of the harmonic oscillator. If we identify $\alpha = g/4$ with the coupling constant in (5.233), to save factors $1/4$, the first coefficient is $a_1 = 3/4$ [see (5.190)]. We have seen before in Section 5.12 that even the lowest order variational perturbation theory yields leading strong-coupling coefficient in excellent agreement with the exact one [with a maximal error of $\approx 2\%$, see Eq. (5.167)]. In Fig. 5.23 we have plotted the relative deviation of the variational approximation from the exact one in percent.

The strong-coupling behavior is known from (5.226). It starts out like $g^{1/3}$, followed by powers of $g^{-1/3}, g^{-1}, g^{-5/3}$. Comparison with (5.234) shows that this

Figure 5.23 Ratio of approximate and exact ground state energy of anharmonic oscillator from lowest-order variational interpolation. Dashed curve shows first-order Feynman-Kleinert approximation $W_1(g)$. The accuracy is everywhere better than 99.5%. For comparison, we also display the much worse (although quite good) variational perturbation result using the exact $a_1^{\text{ex}} = 3/4$.

corresponds to $p = 1$ and $q = 3$. The leading coefficient is given in Table 5.9 with extreme accuracy: $b_0 = 0.667\,986\,259\,155\,777\,108\,270\,962\,016\,919\,860 \dots$.

In a variational interpolation, this value is used to determine an approximate a_1 (forgetting that we know the exact value $a_1^{\text{ex}} = 3/4$). The energy (5.238) reads for $N = 1$ (with $\alpha = g/4$ instead of g):

$$W_1(\alpha, \Omega) = \left(\frac{\Omega}{2} + \frac{1}{2\Omega} \right) a_0 + \frac{a_1}{\Omega^2} \alpha. \quad (5.250)$$

Equation (5.245) yields, for $n = 0$:

$$b_0 = \frac{c}{2} a_0 + \frac{a_1}{c^2}. \quad (5.251)$$

Minimizing b_0 with respect to c we find $c = c_1 \equiv 2(a_1/2a_0)^{1/3}$ with $b_0 = 3a_0c_1/4 = 3(a_0^2a_1/2)^{1/3}/2$. Inserting this into (5.251) fixes $a_1 = 2(2/3b_0)^3/a_0^2 = 0.773\,970 \dots$, quite close to the exact value $3/4$. With our approximate a_1 we calculate $W_1(\alpha, \Omega)$ at its minimum, where

$$\Omega_1 = \begin{cases} \frac{2}{\sqrt{3}} \omega \cosh \left[\frac{1}{3} \alpha \cosh(g/g^{(0)}) \right] & \text{for } g > g^{(0)}, \\ \frac{2}{\sqrt{3}} \omega \cos \left[\frac{1}{3} \arccos(g/g^{(0)}) \right] & \text{for } g < g^{(0)}, \end{cases} \quad (5.252)$$

with $g^{(0)} \equiv 2\omega^3 a_0 / 3\sqrt{3} a_1$. The result is shown in Fig. 5.23. Since the difference with respect to the exact solution would be too small to be visible on a direct plot of the energy, we display the ratio with respect to the exact energy $W_1(g)/E_{\text{ex}}^0$. The accuracy is everywhere better than 99.5%.

5.19 Systematic Improvement of Excited Energies

The variational method for the energies of excited states developed in Section 5.12 can also be improved systematically. Recall the n -dependent level shift formulas (3.518) and (3.519), according to which

$$\begin{aligned} \Delta E^{(n)} &= \Delta_1 E^{(n)} + \Delta_2 E^{(n)} + \Delta_3 E^{(n)} = \Delta V_{nn} - \sum_{k \neq n} \frac{\Delta V_{nk} \Delta V_{kn}}{E_k - E_n} \\ &+ \sum_{k \neq n} \sum_{l \neq n} \frac{\Delta V_{nk} \Delta V_{kl} \Delta V_{ln}}{(E_k - E_n)(E_l - E_n)} - \Delta V_{nn} \sum_{k \neq n} \frac{\Delta V_{nk} \Delta V_{kn}}{(E_k - E_n)^2}. \end{aligned} \quad (5.253)$$

By applying the substitution rule (5.188) to the total energies

$$E^{(n)} = \hbar\Omega(n + 1/2) + \Delta E^{(n)},$$

and expanding each term in powers of g up to g^3 , we find the contributions to the level shift

$$\begin{aligned} \Delta_1 E^{(n)} &= \frac{g}{4} [3(2n^2 + 2n + 1)a^4 + (2n + 1)a^2 r^2], \\ \Delta_2 E^{(n)} &= - \left(\frac{g}{4}\right)^2 [2(34n^3 + 51n^2 + 59n + 21)a^8 \\ &+ 4 \cdot 3(2n^2 + 2n + 1)a^6 r^2 + (2n + 1)a^4 r^4] \frac{1}{\hbar\Omega}, \\ \Delta_3 E^{(n)} &= \left(\frac{g}{4}\right)^3 [4 \cdot 3(125n^4 + 250n^3 + 472n^2 + 347n + 111)a^{12} \\ &+ 4 \cdot 5(34n^3 + 51n^2 + 59n + 21)a^{10} r^2 \\ &+ 16 \cdot 3(2n^2 + 2n + 1)a^8 r^4 + 2 \cdot (2n + 1)a^6 r^6] \frac{1}{\hbar^2 \Omega^2}, \end{aligned} \quad (5.254)$$

which for $n = 0$ reduce to the corresponding terms in (5.192). The extremization in Ω leads to energies which lie only very little above the exact values for all n . This is illustrated in Table 5.11 for $n = 8$ (compare with the energies in Table 5.5). A sum over the Boltzmann factors $e^{-\beta E_3^{(n)}}$ produces an approximate partition function Z_3 which deviates from the exact one by less than 50.1%.

It will be interesting to use the improved variational approach for the calculation of density matrices, particle distributions, and magnetization curves.

Table 5.11 Higher approximations to excited energy with $n = 8$ of anharmonic oscillator at various coupling constants g . The third-order approximation $E_3^{(8)}(g)$ is compared with the exact values $E_{\text{ex}}^{(8)}(g)$, with the approximation $E_1^{(8)}(g)$ of the last section, and with the lower approximation of even order $E_2^{(8)}(g)$ (all in units of $\hbar\omega$).

5.20 Variational Treatment of Double-Well Potential

Let us also calculate the approximate effective classical potential of third order $W_3(x_0)$ for the double-well potential

$$V(x) = M \frac{\omega^2}{2} x^2 + \frac{g}{4} x^4 + \frac{M^2 \omega^4}{4g}, \quad \omega^2 = -1. \quad (5.255)$$

In the expression (5.197), the sign change of ω^2 affects only the coupling $g_2(x_0)$, which becomes

$$g_2(x_0) = M[-1 - \Omega^2(x_0)] + 3gx_0^2 = gr^2/2 + 3gx_0^2 \quad (5.256)$$

[recall (5.176)]. Note the constant energy $M^2\omega^4/4g$ in $V(x)$ which shifts the minima of the potential to zero [compare (5.78)].

To see the improved accuracy of W_3 with respect to the first approximation $W_1(x_0)$ discussed in Section 5.7 [corresponding to the first line of (5.197)], we study the limit of zero temperature where the accuracy is expected to be the worst. In this limit, $W_3(x_0)$ reduces to (5.201) and is easily minimized in x_0 and Ω .

At larger coupling constants $g > g_c \approx 0.3$, the energy has a minimum at $x_0 = 0$. For $g \leq g_c$, there is an additional symmetric pair of minima at $x_0 = \pm x_m \neq 0$ (recall Figs. 5.5 and 5.6). The resulting $W_3(0)$ is plotted in Fig. 5.24 together with $W_1(0)$. The figure also contains the first excited energy which is obtained by setting $\omega^2 = -1$ in $r^2 = 2M(\omega^2 - \Omega^2)/g$ of Eqs. (5.253)–(5.255).

For small couplings g , the energies $W_1(0)$, $W_3(0)$, \dots diverge and the minima at $x = \pm x_m$ of Eq. (5.82) become relevant. Moreover, there is quantum tunneling across the central barrier from one minimum to the other which takes place for $g \leq g_c \approx 0.3$ and is unaccounted for by $W_3(0)$ and $W_3(x_m)$. Tunneling leads to a level splitting to be calculated in Chapter 17. In this chapter, we test the accuracy of $W_1(x_m)$ and $W_3(x_m)$ by comparing them with the averages of the two lowest energies. Figure 5.24 shows that the accuracy of the approximation $W_3(x_m)$ is quite good.

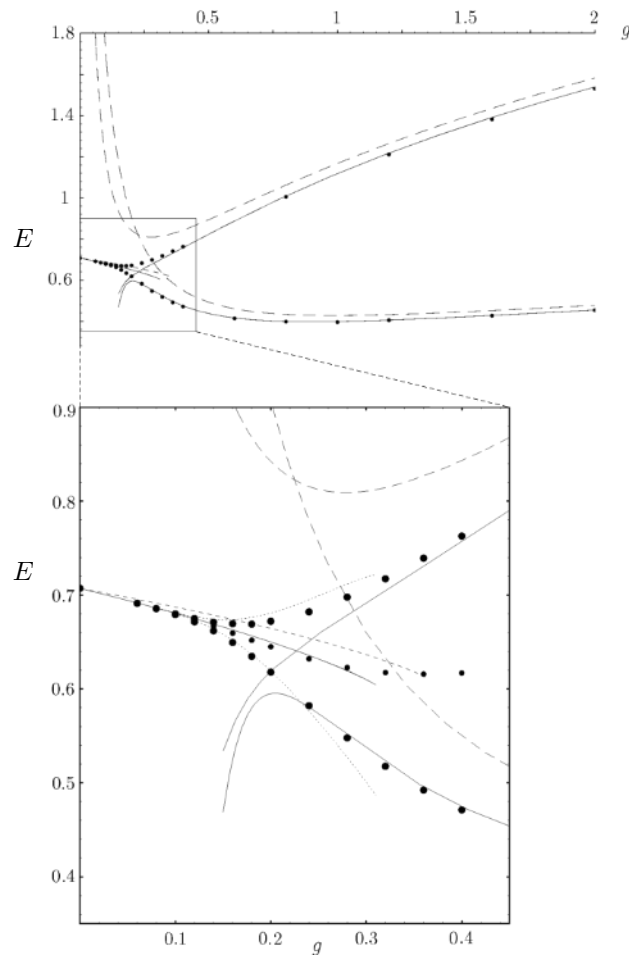

Figure 5.24 Lowest two energies in double-well potential as function of coupling strength g . The approximations are $W_1(0)$ (dashed line) and $W_3(0)$ (solid line). The dots indicate numeric results of the Schrödinger equation. The lower part of the figure shows $W_1(x_m)$ and $W_3(0)$ in comparison with the average of the Schrödinger energies (small dots). Note that W_1 misses the slope by 25%. Tunneling causes a level splitting to be calculated in Chapter 17 (dotted curves).

Note that the approximation $W_1(x_m)$ does not possess the correct slope in g , which is missed by 25%. In fact, a Taylor expansion of $W_1(x_m)$ reads

$$W_1(x_m) = \frac{\sqrt{2}}{2} - \frac{3}{16}g - \frac{9\sqrt{2}}{128}g^2 - \frac{27}{256}g^3 + \dots, \quad (5.257)$$

whereas the true expansion starts out with

$$E^{(0)} = \frac{\sqrt{2}}{2} - \frac{1}{4}g + \dots. \quad (5.258)$$

The optimal frequency associated with (5.257) has the expansion

$$\Omega_1(x_m) = \sqrt{2} - \frac{3}{4}g - \frac{27\sqrt{2}}{64}g^2 - \frac{27}{32}g^3 + \dots.$$

Let us also compare the x_0 -behavior of $W_3(x_0)$ with that of the true effective classical potential calculated numerically by Monte Carlo simulations. The curves are plotted in Fig. 5.5, and the

agreement is seen to be excellent. There are significant deviations only for low temperatures with $\beta \gtrsim 20$.

At zero temperature, there exists a simple way of recovering the effective classical potential from the classical potential calculated up to two loops in Eq. (3.770). As we learned in Eq. (3.833), x_0 coincides at zero temperature. with X in Eq. (3.770) Thus we merely have to employ the square-root trick (5.186) to the effective potential (3.770) and interchange X by x_0 to obtain the variational approximation $W_1(x_0)$ to the effective classical potential to be varied. Explicitly, we replace, as in (5.188), the one-loop contributions, ground state energies $\hbar\omega_{T,L}$ in (3.770) by $\sqrt{\Omega_{T,L}^2 + (\omega_{T,L}^2(X) - \Omega_{T,L}^2)}$ $\approx \Omega_{T,L} + (\omega_{T,L}^2(X) - \Omega_{T,L}^2)/2\Omega_{T,L}$, and exchange $\omega_{L,T}(X)$ of the remaining two-loop terms by $\Omega_{T,L}$. This yields for the D -dimensional rotated double-well potential (the Mexical hat potential in Fig. 3.13]:

$$\begin{aligned}
 W(x_0) \stackrel{T \rightarrow 0}{=} & \left\{ v(X) + \hbar \left[\frac{\Omega_L}{4} + \frac{\omega_L^2(X)}{4\Omega_L} \right] + (D-1)\hbar \left[\frac{\Omega_T}{4} + \frac{\omega_T^2(X)}{4\Omega_T} \right] + \frac{\hbar^2}{8(2M)^2} \left\{ \frac{1}{\Omega_L^2} v^{(4)}(X) \right. \right. \\
 & + \frac{D^2-1}{\Omega_T^2} \left[\frac{v''(X)}{X^2} - \frac{v'(X)}{X^3} \right] + \frac{2(D-1)}{\Omega_L\Omega_T} \left[\frac{v'''(X)}{X} - \frac{2v''(X)}{X^2} + \frac{2v'(X)}{X^3} \right] \left. \right\} \\
 & - \frac{\hbar^2}{6(2M)^3} \left\{ \frac{1}{3\Omega_L^4} [v'''(X)]^2 + \frac{3(D-1)}{2\Omega_T + \Omega_L} \frac{1}{\Omega_L\Omega_T^2} \left[\frac{v''(X)}{X} - \frac{v'(X)}{X^2} \right]^2 \right\} + \mathcal{O}(\hbar^3) \Bigg\}_{X \rightarrow x_0}. \quad (5.259)
 \end{aligned}$$

This has to be extremized in $\Omega_{T,L}$ at fixed x_0 .

5.21 Higher-Order Effective Classical Potential for Nonpolynomial Interactions

The systematic improvement of the Feynman-Kleinert approximation in Section 5.13 was based on Feynman diagrams and therefore applicable only to polynomial potentials. If we want to calculate higher-order effective classical potentials for nonpolynomial interactions such as the Coulomb interaction, we need a generalization of the smearing rule (5.30) to the correlation functions of interaction potentials which occur in the expansion (5.180). The second-order term, for example, requires the calculation of

$$\langle \mathcal{A}_{\text{int}}^{x_0,2} \rangle_{\Omega,c}^{x_0} = \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \langle V_{\text{int}}^{x_0}(x(\tau)) V_{\text{int}}^{x_0}(x(\tau')) \rangle_{\Omega,c}^{x_0}, \quad (5.260)$$

where

$$V_{\text{int}}^{x_0}(x) = V(x) - \frac{1}{2} M \Omega^2 (x_0) (x - x_0)^2. \quad (5.261)$$

Thus we need an efficient smearing formula for local expectations of the form

$$\begin{aligned}
 \langle F_1(x(\tau_1)) \dots F_n(x(\tau_n)) \rangle_{\Omega}^{x_0} &= \frac{1}{Z_{\Omega}^{x_0}} \\
 &\times \oint \mathcal{D}x(\tau) F_1(x(\tau_1)) \dots F_n(x(\tau_n)) \delta(\bar{x} - x_0) \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_{\Omega}^{x_0}[x(\tau)] \right\}, \quad (5.262)
 \end{aligned}$$

where $\mathcal{A}_{\Omega}^{x_0}[x(\tau)]$ and $Z_{\Omega}^{x_0}$ are the local action and partition function of Eqs. (5.3) and (5.4). After rearranging the correlation functions to connected ones according to Eqs. (5.182) we find the cumulant expansion for the effective classical potential [see (5.180)]

$$V^{\text{eff,cl}}(x_0) = F_{\Omega}^{x_0} + \frac{1}{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 \langle V_{\text{int}}^{x_0}(x(\tau_1)) \rangle_{\Omega,c}^{x_0}$$

$$\begin{aligned}
& - \frac{1}{2\hbar^2\beta} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 \langle V_{\text{int}}^{x_0}(x(\tau_1))V_{\text{int}}^{x_0}(x(\tau_2)) \rangle_{\Omega,c}^{x_0} \\
& + \frac{1}{6\hbar^3\beta} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 \int_0^{\hbar\beta} d\tau_3 \langle V_{\text{int}}^{x_0}(x(\tau_1))V_{\text{int}}^{x_0}(x(\tau_2))V_{\text{int}}^{x_0}(x(\tau_3)) \rangle_{\Omega,c}^{x_0} + \dots
\end{aligned} \tag{5.263}$$

It differs from the previous expansion (5.180) for polynomial interactions by the potential $V(x)$ not being expanded around x_0 . The first term on the right-hand side is the local free energy (5.6).

5.21.1 Evaluation of Path Integrals

The local pair correlation function was given in Eq. (5.19):

$$\langle \delta x(\tau)\delta x(\tau') \rangle_{\Omega}^{x_0} \equiv \langle [x(\tau) - x_0][x(\tau') - x_0] \rangle_{\Omega}^{x_0} = \frac{\hbar}{M} G_{\Omega}^{(2)x_0}(\tau, \tau') = a_{\tau\tau'}^2(x_0), \tag{5.264}$$

with [recall (5.19)–(5.24)]

$$a_{\tau\tau'}^2(x_0) = \frac{\hbar}{2M\Omega(x_0)} \frac{\cosh[\Omega(x_0)(\tau - \tau' - \hbar\beta/2)]}{\sinh[\Omega(x_0)\hbar\beta/2]} - \frac{1}{M\beta\Omega^2(x_0)}, \quad \tau \in (0, \hbar\beta). \tag{5.265}$$

Higher correlation functions are expanded in products of these according to Wick's rule (3.305). For an even number of $\delta x(\tau)$'s one has

$$\langle \delta x(\tau_1)\delta x(\tau_2)\cdots\delta x(\tau_n) \rangle_{\Omega}^{x_0} = \sum_{\text{pairs}} a_{\tau_{p(1)}\tau_{p(2)}}^2(x_0)\cdots a_{\tau_{p(n-1)}\tau_{p(n)}}^2(x_0), \tag{5.266}$$

where the sum runs over all $(n-1)!!$ pair contractions. For an exponential, Wick's rule implies

$$\left\langle \exp \left[i \int_0^{\hbar\beta} d\tau j(\tau) \delta x(\tau) \right] \right\rangle_{\Omega}^{x_0} = \exp \left[-\frac{1}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) a_{\tau\tau'}^2(x_0) j(\tau') \right]. \tag{5.267}$$

Inserting $j(\tau) = \sum_{i=1}^n k_i \delta(\tau - \tau_i)$, this gives for the expectation value of a sum of exponentials

$$\left\langle \exp \left[i \sum_{i=1}^n k_i \delta x(\tau_i) \right] \right\rangle_{\Omega}^{x_0} = \exp \left[-\frac{1}{2} \sum_{i=1}^n \sum_{j=1}^n a_{\tau_i\tau_j}^2(x_0) k_i k_j \right]. \tag{5.268}$$

By Fourier-decomposing the functions $F(x(\tau)) = \int (dk/2\pi) F(k) \exp ik[x_0 + \delta x(\tau)]$ in (5.262), we obtain from (5.268) the new smearing formula

$$\begin{aligned}
& \langle F_1(x(\tau_1)) \cdots F_n(x(\tau_n)) \rangle_{\Omega}^{x_0} = \left\{ \prod_{k=1}^n \int_{-\infty}^{+\infty} d\delta x_k F_k(x_0 + \delta x_k) \right\} \\
& \times \frac{1}{\sqrt{(2\pi)^n \text{Det} [a_{\tau_k\tau_{k'}}^2(x_0)]}} \exp \left\{ -\frac{1}{2} \sum_{k=1}^n \sum_{k'=1}^n \delta x_k a_{\tau_k\tau_{k'}}^{-2}(x_0) \delta x_{k'} \right\},
\end{aligned} \tag{5.269}$$

where $a_{\tau_i\tau_j}^{-2}(x_0)$ is the inverse of the $n \times n$ -matrix $a_{\tau_i\tau_j}^2(x_0)$. This smearing formula determines the harmonic expectation values in the variational perturbation expansion (5.263) as convolutions with Gaussian functions.

For $n = 1$ and only the diagonal elements $a^2(x_0) = a_{\tau\tau}^2(x_0)$ appear in the smearing formula (5.269), which reduces to the previous one in Eq. (5.30) [$F(x(\tau)) = V(x(\tau))$].

For polynomials $F(x(\tau))$, we set $x(\tau) = x_0 + \delta x(\tau)$ and expand in powers of $\delta x(\tau)$, and see that the smearing formula (5.269) reproduces the Wick expansion (5.266).

For two functions, the smearing formula (5.269) reads explicitly

$$\begin{aligned} \langle F_1(x(\tau_1))F_2(x(\tau_2)) \rangle_{\Omega}^{x_0} &= \int_{-\infty}^{+\infty} dx_1 \int_{-\infty}^{+\infty} dx_2 F_1(x_1)F_2(x_2) \frac{1}{\sqrt{(2\pi)^2[a^4(x_0) - a_{\tau_1\tau_2}^4(x_0)]}} \\ &\times \exp \left\{ -\frac{a^2(x_0)(x_1 - x_0)^2 - 2a_{\tau_1\tau_2}^2(x_0)(x_1 - x_0)(x_2 - x_0) + a^2(x_0)(x_2 - x_0)^2}{2[a^4(x_0) - a_{\tau_1\tau_2}^4(x_0)]} \right\}. \end{aligned} \quad (5.270)$$

Specializing $F_2(x(\tau_2))$ to quadratic functions in $x(\tau)$, we obtain from this

$$\begin{aligned} \langle F_1(x(\tau_1)) [x(\tau_2) - x_0]^2 \rangle_{\Omega}^{x_0} &= \langle F_1(x(\tau_1)) \rangle_{\Omega}^{x_0} a^2(x_0) \left[1 - \frac{a_{\tau_1\tau_2}^4(x_0)}{a^4(x_0)} \right] \\ &+ \langle F_1(x(\tau_1)) [x(\tau_1) - x_0]^2 \rangle_{\Omega}^{x_0} \frac{a_{\tau_1\tau_2}^4(x_0)}{a^4(x_0)}, \end{aligned} \quad (5.271)$$

and

$$\langle [x(\tau_1) - x_0]^2 [x(\tau_2) - x_0]^2 \rangle_{\Omega}^{x_0} = a^4(x_0) + 2a_{\tau_1\tau_2}^4(x_0). \quad (5.272)$$

5.21.2 Higher-Order Smearing Formula in D Dimensions

The smearing formula can easily be generalized to D -dimensional systems, where the local pair correlation function (5.264) becomes a $D \times D$ -dimensional matrix:

$$\langle \delta x_i(\tau) \delta x_j(\tau') \rangle_{\Omega}^{x_0} = a_{ij;\tau\tau'}^2(\mathbf{x}_0). \quad (5.273)$$

For rotationally-invariant systems, the matrix can be decomposed in the same way as the trial frequency $\Omega_{ij}^2(\mathbf{x}_0)$ in (5.95) into longitudinal and transversal components with respect to \mathbf{x}_0 :

$$a_{ij;\tau\tau'}^2(\mathbf{x}_0) = a_{L;\tau\tau'}^2(r_0)P_{L;ij}(\hat{\mathbf{x}}_0) + a_{T;\tau\tau'}^2(r_0)P_{T;ij}(\hat{\mathbf{x}}_0), \quad (5.274)$$

where $P_{L;ij}(\hat{\mathbf{x}}_0)$ and $P_{T;ij}(\hat{\mathbf{x}}_0)$ are longitudinal and transversal projection matrices introduced in (5.96). Denoting the matrix (5.274) by $\mathbf{a}_{\tau,\tau'}^2(\mathbf{x}_0)$, we can write the D -dimensional generalization of the smearing formula (5.275) as

$$\begin{aligned} \langle F_1(\mathbf{x}(\tau_1)) \cdots F_n(\mathbf{x}(\tau_n)) \rangle_{\Omega}^{x_0} &= \left\{ \prod_{k=1}^n \int_{-\infty}^{+\infty} d\delta \mathbf{x}_k F_k(\mathbf{x}_0 + \delta \mathbf{x}_k) \right\} \\ &\times \frac{1}{\sqrt{(2\pi)^n \text{Det} [\mathbf{a}_{\tau_k\tau_{k'}}^2(\mathbf{x}_0)]}} \exp \left\{ -\frac{1}{2} \sum_{k=1}^n \sum_{k'=1}^n \delta \mathbf{x}_k \mathbf{a}_{\tau_k\tau_{k'}}^{-2}(x_0) \delta \mathbf{x}_{k'} \right\}. \end{aligned} \quad (5.275)$$

The inverse $D \times D$ -matrix $\mathbf{a}_{\tau_k\tau_{k'}}^{-2}(\mathbf{x}_0)$ is formed by simply inverting the $n \times n$ -matrices $\mathbf{a}_{L;\tau_k\tau_{k'}}^{-2}(r_0)$, $\mathbf{a}_{T;\tau_k\tau_{k'}}^{-2}(r_0)$ in the projection formula (5.274) with projection matrices $\mathbf{P}_L(\hat{\mathbf{x}}_0)$ and $\mathbf{P}_T(\hat{\mathbf{x}}_0)$:

$$\mathbf{a}_{\tau_k\tau_{k'}}^{-2}(\mathbf{x}_0) = \mathbf{a}_{L;\tau_k\tau_{k'}}^{-2}(r_0)\mathbf{P}_L(\hat{\mathbf{x}}_0) + \mathbf{a}_{T;\tau_k\tau_{k'}}^{-2}(r_0)\mathbf{P}_T(\hat{\mathbf{x}}_0). \quad (5.276)$$

In D dimensions, the trial potential contains a $D \times D$ frequency matrix and reads

$$\frac{M}{2} \Omega_{ij}^2(\mathbf{x}_0) (x_i - x_{0i})(x_j - x_{0j}),$$

with the analogous decomposition

$$\Omega_{ij}^2(\mathbf{x}_0) = \Omega_L^2(\mathbf{x}_0) \frac{x_{0i}x_{0j}}{r_0^2} + \Omega_T^2(\mathbf{x}_0) \left(\delta_{ij} - \frac{x_{0i}x_{0j}}{r_0^2} \right). \quad (5.277)$$

The interaction potential (5.261) becomes

$$V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}) = V(\mathbf{x}) - \frac{M}{2} \Omega_{ij}^2(\mathbf{x}_0) (x_i - x_{0i})(x_j - x_{0j}). \quad (5.278)$$

To first order, the anisotropic smearing formula (5.275) reads

$$\langle F_1(\mathbf{x}(\tau_1)) \rangle_{\Omega_T, \Omega_L}^{r_0} = \int_{-\infty}^{+\infty} d^3x_1 F_1(\mathbf{x}_1) \frac{1}{\sqrt{(2\pi)^3 a_T^4 a_L^2}} \exp \left\{ -\frac{(x_{1L} - r_0)^2}{2a_L^2} - \frac{\mathbf{x}_{1T}^2}{2a_T^2} \right\}, \quad (5.279)$$

with the special cases

$$\left\langle [\delta\mathbf{x}(\tau_1)]_T^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} = 2a_T^2, \quad \left\langle [\delta\mathbf{x}(\tau_1)]_L^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} = a_L^2. \quad (5.280)$$

Inserting this into formula (5.263) we obtain the first-order approximation for the effective classical potential

$$W_1(\mathbf{x}_0) = F_{\Omega}^{\mathbf{x}_0} + \frac{1}{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 \langle V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}(\tau_1)) \rangle_{\Omega, c}^{\mathbf{x}_0}, \quad (5.281)$$

in agreement with the earlier result (5.97).

To second-order, the smearing formula (5.275) yields [33]

$$\begin{aligned} \langle F_1(\mathbf{x}(\tau_1)) F_2(\mathbf{x}(\tau_2)) \rangle_{\Omega_T, \Omega_L}^{r_0} &= \int_{-\infty}^{+\infty} d^3x_1 \int_{-\infty}^{+\infty} d^3x_2 F_1(\mathbf{x}_1) F_2(\mathbf{x}_2) \\ &\times \frac{1}{(2\pi)^3 (a_T^4 - a_{T\tau_1\tau_2}^4) \sqrt{a_L^4 - a_{L\tau_1\tau_2}^4}} \exp \left\{ -\frac{a_T^2 \mathbf{x}_{1T}^2 - 2a_{T\tau_1\tau_2}^2 \mathbf{x}_{1T} \mathbf{x}_{2T} + a_T^2 \mathbf{x}_{2T}^2}{2(a_T^4 - a_{T\tau_1\tau_2}^4)} \right\} \\ &\times \exp \left\{ -\frac{a_L^2 (x_{1L} - r_0)^2 - 2a_{L\tau_1\tau_2}^2 (x_{1L} - r_0)(x_{2L} - r_0) + a_L^2 (x_{2L} - r_0)^2}{2(a_L^4 - a_{L\tau_1\tau_2}^4)} \right\}, \end{aligned} \quad (5.282)$$

so that rule (5.271) for expectation values generalizes to

$$\begin{aligned} \left\langle F_1(\mathbf{x}(\tau_1)) [\delta\mathbf{x}(\tau_2)]_T^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} &= 2a_T^2 \left[1 - \frac{a_{T\tau_1\tau_2}^4}{a_T^4} \right] \langle F_1(\mathbf{x}(\tau_1)) \rangle_{\Omega_T, \Omega_L}^{r_0} \\ &+ \frac{a_{T\tau_1\tau_2}^4}{a_T^4} \left\langle F_1(\mathbf{x}(\tau_1)) [\delta\mathbf{x}(\tau_1)]_T^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0}, \end{aligned} \quad (5.283)$$

$$\begin{aligned} \left\langle F_1(\mathbf{x}(\tau_1)) [\delta\mathbf{x}(\tau_2)]_L^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} &= a_L^2 \left[1 - \frac{a_{L\tau_1\tau_2}^4}{a_L^4} \right] \langle F_1(\mathbf{x}(\tau_1)) \rangle_{\Omega_T, \Omega_L}^{r_0} \\ &+ \frac{a_{L\tau_1\tau_2}^4}{a_L^4} \langle F_1(\mathbf{x}(\tau_1)) [\delta\mathbf{x}(\tau_1)]_L^2 \rangle_{\Omega_T, \Omega_L}^{r_0}. \end{aligned} \quad (5.284)$$

Specializing $F(\mathbf{x})$ to quadratic function, we obtain the generalizations of (5.272)

$$\left\langle [\delta\mathbf{x}(\tau_1)]_T^2 [\delta\mathbf{x}(\tau_2)]_T^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} = 4a_T^4 + 4a_{T\tau_1\tau_2}^4, \quad (5.285)$$

$$\left\langle [\delta\mathbf{x}(\tau_1)]_T^2 [\delta\mathbf{x}(\tau_2)]_L^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} = 2a_T^2 a_L^2, \quad (5.286)$$

$$\left\langle [\delta\mathbf{x}(\tau_1)]_L^2 [\delta\mathbf{x}(\tau_2)]_L^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} = a_L^4 + 2a_{L\tau_1\tau_2}^4. \quad (5.287)$$

5.21.3 Isotropic Second-Order Approximation to Coulomb Problem

To demonstrate the use of the higher-order smearing formula (5.275), we calculate the effective classical potential of the three-dimensional Coulomb potential

$$V(\mathbf{x}) = -\frac{e^2}{|\mathbf{x}|} \quad (5.288)$$

to second order in variational perturbation theory, thus going beyond the earlier results in Eq. (5.53) and Section 5.10. The interaction potential corresponding to (5.278) is

$$V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}) = -\frac{e^2}{|\mathbf{x}|} - \frac{M}{2}\Omega^2(\mathbf{x}_0)(\mathbf{x} - \mathbf{x}_0)^2. \quad (5.289)$$

For simplicity, we consider only the isotropic approximation with only a single trial frequency. Then all formulas derived in the beginning of this section have a trivial extension to three dimensions. Better results will, of course be obtained with two trial frequencies $\Omega_L^2(r_0)$ and $\Omega_T^2(r_0)$ of Section 5.9.

The Fourier transform $4\pi e^2/|\mathbf{k}|^2$ of the Coulomb potential $e^2/|\mathbf{x}|$ is most conveniently written in a proper-time type of representation as

$$V(\mathbf{k}) = \frac{4\pi e^2}{2} \int_0^\infty d\sigma e^{-\sigma \mathbf{k}^2/2 - i\mathbf{k}\mathbf{x}}, \quad (5.290)$$

where σ has the dimension length square. The lowest-order smeared potentials were calculated before in Section 5.10. For brevity, we consider here only the isotropic approximation in which longitudinal and transverse trial frequencies are identified [compare (5.112)]:

$$\left\langle [\mathbf{x}(\tau_1) - \mathbf{x}_0]^2 \right\rangle_\Omega^{\mathbf{x}_0} = 3a^2(\mathbf{x}_0), \quad \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} \right\rangle_\Omega^{\mathbf{x}_0} = \frac{1}{|\mathbf{x}_0|} \operatorname{erf} \left[\frac{|\mathbf{x}_0|}{\sqrt{2a^2(\mathbf{x}_0)}} \right]. \quad (5.291)$$

The first-order variational approximation to the effective classical potential (5.281) is then given by the earlier-calculated expression (5.115).

To second order in variational perturbation theory we calculate expectation values

$$\left\langle [\mathbf{x}(\tau_1) - \mathbf{x}_0]^2 [\mathbf{x}(\tau_2) - \mathbf{x}_0]^2 \right\rangle_\Omega^{\mathbf{x}_0} = 9a^4(\mathbf{x}_0) + 6a_{\tau_1\tau_2}^4(\mathbf{x}_0), \quad (5.292)$$

$$\left\langle [\mathbf{x}(\tau_1) - \mathbf{x}_0]^2 \frac{1}{|\mathbf{x}(\tau_2)|} \right\rangle_\Omega^{\mathbf{x}_0} = \frac{2[3a^4(\mathbf{x}_0) - a_{\tau_1\tau_2}^4(\mathbf{x}_0)]}{\sqrt{\pi a^6(\mathbf{x}_0)}}, \quad (5.293)$$

which follow from the obvious generalization of (5.271), (5.272) to three dimensions. More involved is the Coulomb-Coulomb correlation function

$$\begin{aligned} \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} \frac{1}{|\mathbf{x}(\tau_2)|} \right\rangle_\Omega^{\mathbf{x}_0} &= \frac{1}{2\pi} \int_0^{+\infty} d\sigma_1 \int_0^{+\infty} d\sigma_2 \frac{1}{\sqrt{[a^2(\mathbf{x}_0) + \sigma_1][a^2(\mathbf{x}_0) + \sigma_2] - a_{\tau_1\tau_2}^4(\mathbf{x}_0)}^3} \\ &\times \exp \left\{ -\mathbf{x}_0^2 \frac{a^2(\mathbf{x}_0) + \sigma_1/2 + \sigma_2/2 - a_{\tau_1\tau_2}^2(\mathbf{x}_0)}{[a^2(\mathbf{x}_0) + \sigma_1][a^2(\mathbf{x}_0) + \sigma_2] - a_{\tau_1\tau_2}^4(\mathbf{x}_0)} \right\}. \end{aligned} \quad (5.294)$$

Using these smearing results we calculate the second connected correlation functions of the interaction potential (5.289) appearing in (5.263) and find the effective classical potential to second order in variational perturbation theory

$$\begin{aligned} W_2(\mathbf{x}_0) &= W_1(\mathbf{x}_0) + \left[\frac{Me^2\Omega(\mathbf{x}_0)}{\hbar\sqrt{2\pi a^6(\mathbf{x}_0)}} - \frac{3M^2\Omega^3(\mathbf{x}_0)}{4\hbar} \right] l^4(\mathbf{x}_0) \\ &\quad - \frac{e^4}{2\hbar} \int_0^{\hbar\beta} d\tau \left\langle \frac{1}{|\mathbf{x}(\tau)|} \frac{1}{|\mathbf{x}(0)|} \right\rangle_\Omega^{\mathbf{x}_0}, \end{aligned} \quad (5.295)$$

with the abbreviation

$$l^4(\mathbf{x}_0) \equiv \frac{\hbar [4 + \hbar^2 \beta^2 \Omega^2(\mathbf{x}_0) - 4 \cosh \hbar \beta \Omega(\mathbf{x}_0) + \hbar \beta \Omega(\mathbf{x}_0) \sinh \hbar \beta \Omega(\mathbf{x}_0)]}{8 \beta M^2 \Omega^3(\mathbf{x}_0) \sinh[\hbar \beta \Omega(\mathbf{x}_0)/2]}, \quad (5.296)$$

the symbol indicating that this is a quantity of dimension length to the fourth power. After an extremization of (5.295) with respect to the trial frequency $\Omega(\mathbf{x}_0)$, which has to be done numerically, we obtain the second-order approximation for the effective classical potential of the Coulomb system plotted in Fig. 5.25 for various temperatures. The curves lie all below the first-order ones, and the difference between the two decreases with increasing temperature and increasing distance from the origin.

Figure 5.25 Isotropic approximation to effective classical potential of Coulomb system in the first (lines) and second order (dots). The temperatures are $10^{-4}, 10^{-3}, 10^{-2}, 10^{-1}$, and ∞ from top to bottom in atomic units. Compare also Fig. 5.9.

5.21.4 Anisotropic Second-Order Approximation to Coulomb Problem

The first-order effective classical potential $W_1(\mathbf{x}_0)$ was derived in Eqs. (5.97) and (5.117)–(5.121). To obtain the second-order approximation $W_2(\mathbf{x}_0)$, we insert the Coulomb potential in the representation (5.290) into the second-order smearing formula (5.282), and find

$$\begin{aligned} \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} [\delta \mathbf{x}(\tau_2)]_T^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} &= \sqrt{\frac{2a_L^2}{\pi}} \int_0^1 d\lambda e^{-\frac{r_0^2}{2a_L^2} \lambda^2} \left\{ \frac{2a_T^2}{(a_T^2 - a_L^2)\lambda^2 + a_L^2} - \frac{2a_{T\tau_1\tau_2}^4 \lambda^2}{[(a_T^2 - a_L^2)\lambda^2 + a_L^2]^2} \right\}, \\ \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} [\delta \mathbf{x}(\tau_2)]_L^2 \right\rangle_{\Omega_T, \Omega_L}^{r_0} &= \sqrt{\frac{2a_L^2}{\pi}} \int_0^1 d\lambda e^{-\frac{r_0^2}{2a_L^2} \lambda^2} \frac{a_L^6 + a_{L\tau_1\tau_2}^4 [r_0^2 \lambda^4 - a_L^2 \lambda^2]}{a_L^4 [(a_T^2 - a_L^2)\lambda^2 + a_L^2]}. \end{aligned} \quad (5.297)$$

These are special cases of the more general expectation value

$$\begin{aligned} \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} F(\mathbf{x}(\tau_2)) \right\rangle_{\Omega_T, \Omega_L}^{r_0} &= \frac{1}{2\pi^2} \int_0^\infty d\sigma \frac{\exp \left\{ -\frac{a_L^2 r_0^2}{2[a_L^4 - a_{L\tau_1\tau_2}^4 + 2a_L^2 \sigma]} \right\}}{[a_T^4 - a_{T\tau_1\tau_2}^4 + 2a_T^2 \sigma] \sqrt{a_L^4 - a_{L\tau_1\tau_2}^4 + 2a_L^2 \sigma}} \\ &\times \int d^3 x F(\mathbf{x}) \exp \left\{ -\frac{(a_T^2 + 2\sigma) \mathbf{x}_T^2}{2[a_T^4 - a_{T\tau_1\tau_2}^4 + 2a_T^2 \sigma]} - \frac{(a_L^2 + 2\sigma)(x_L - r_0)^2 + 2a_{L\tau_1\tau_2}^2 r_0(x_L - r_0)}{2[a_L^4 - a_{L\tau_1\tau_2}^4 + 2a_L^2 \sigma]} \right\}, \end{aligned} \quad (5.298)$$

which furthermore leads to

$$\left\langle \frac{1}{|\mathbf{x}(\tau_1)|} \frac{1}{|\mathbf{x}(\tau_2)|} \right\rangle_{\Omega_T, \Omega_L}^{r_0} = \frac{2}{\pi} \int_0^{+\infty} d\sigma_1 \int_0^{+\infty} d\sigma_2 \frac{1}{[a_T^2 + 2\sigma_1][a_T^2 + 2\sigma_2] - a_{T\tau_1\tau_2}^4} \\ \times \frac{1}{\sqrt{[a_L^2 + 2\sigma_1][a_L^2 + 2\sigma_2] - a_{L\tau_1\tau_2}^4}} \exp \left\{ -\frac{r_0^2 [a_L^2 + \sigma_1 + \sigma_2 - a_{L\tau_1\tau_2}^2]}{[a_L^2 + 2\sigma_1][a_L^2 + 2\sigma_2] - a_{L\tau_1\tau_2}^4} \right\}. \quad (5.299)$$

From these smearing results we calculate the second-order approximation to the effective classical potential

$$W_2(\mathbf{x}_0) = F_{\Omega}^{\mathbf{x}_0} + \frac{1}{\hbar\beta} \int_0^{\hbar\beta} d\tau_1 \langle V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}(\tau_1)) \rangle_{\Omega, c}^{\mathbf{x}_0} - \frac{1}{2\hbar^2\beta} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 \langle V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}(\tau_1)) V_{\text{int}}^{\mathbf{x}_0}(\mathbf{x}(\tau_2)) \rangle_{\Omega, c}^{\mathbf{x}_0}. \quad (5.300)$$

The result is

$$W_2^{\Omega_T, \Omega_L}(r_0) = W_1^{\Omega_T, \Omega_L}(r_0) \\ + \frac{e^2 M}{2\hbar} \sqrt{\frac{2a_L^2}{\pi}} \int_0^1 d\lambda \left\{ \frac{2\Omega_T l_T^4 \lambda^2}{[(a_T^2 - a_L^2)\lambda^2 + a_L^2]^2} - \frac{\Omega_L l_L^4 [r_0^2 \lambda^4 - a_L^2 \lambda^2]}{a_L^4 [(a_T^2 - a_L^2)\lambda^2 + a_L^2]} \right\} e^{-r_0^2 \lambda^2 / 2a_L^2} \\ - \frac{M^2 [2\Omega_T^3 l_T^4 + \Omega_L^3 l_L^4]}{4\hbar} - \frac{e^4}{2\hbar^2\beta} \int_0^{\hbar\beta} d\tau_1 \int_0^{\hbar\beta} d\tau_2 \left\langle \frac{1}{|\mathbf{x}(\tau_1)|} \frac{1}{|\mathbf{x}(\tau_2)|} \right\rangle_{\Omega_T, \Omega_L, c}^{r_0}, \quad (5.301)$$

with the abbreviation

$$l_{T,L}^4 = \frac{\hbar [4 + \hbar^2 \beta^2 \Omega_{T,L}^2 - 4 \cosh \hbar\beta\Omega_{T,L} + \hbar\beta\Omega_{T,L} \sinh \hbar\beta\Omega_{T,L}]}{8\beta M^2 \Omega_{T,L}^3 \sinh[\hbar\beta\Omega_{T,L}/2]}, \quad (5.302)$$

which is a quantity of dimension (length)⁴. After an extremization of (5.115) and (5.301) with respect to the trial frequencies Ω_T, Ω_L which has to be done numerically, we obtain the second-order approximation for the effective classical potential of the Coulomb system plotted in Fig. 5.26 for various temperatures. The second order curves lie all below the first-order ones, and the difference between the two decreases with increasing temperature and increasing distance from the origin.

5.21.5 Zero-Temperature Limit

As a cross check of our result we take (5.301) to the limit $T \rightarrow 0$. Just as in the lowest-order discussion in Sect. (5.4), the x_0 -integral can be evaluated in the saddle-point approximation which becomes exact in this limit, so that the minimum of $W_N(\mathbf{x}_0)$ in x_0 yields the n th approximation to the free energy at $T = 0$ and thus the n th approximations $E_N^{(0)}$ the ground state energy $E^{(0)}$ of the Coulomb system. In this limit, the results should coincide with those derived from a direct variational treatment of the Rayleigh-Schrödinger perturbation expansion in Section 3.18. With the help of such a treatment, we shall also carry the approximation to the next order, thereby illustrating the convergence of the variational perturbation expansions. For symmetry reasons, the minimum of the effective classical potential occurs for all temperatures at the origin, such that we may restrict (5.115) and (5.301) to this point. Recalling the zero-temperature limit of the two-point correlations (5.19) from (3.249),

$$\lim_{\beta \rightarrow \infty} a_{\tau\tau'}^2(\mathbf{x}_0) = \frac{\hbar}{2M\Omega(\mathbf{x}_0)} \exp \{-\Omega(\mathbf{x}_0) |\tau - \tau'|\}, \quad (5.303)$$

we immediately deduce for the first order approximation (5.115) with $\Omega = \Omega(\mathbf{0})$ the limit

$$E_1^{(0)}(\Omega) = \lim_{\beta \rightarrow \infty} W_1^\Omega(\mathbf{0}) = \frac{3}{4}\hbar\Omega - \frac{2}{\sqrt{\pi}}\sqrt{\frac{M\Omega}{\hbar}}e^2. \tag{5.304}$$

In the second-order expression (5.301), the zero-temperature limit is more tedious to take. Performing the integrals over σ_1 and σ_2 , we obtain the connected correlation function

$$\left\langle \frac{1}{|\mathbf{x}(\tau_1)|} \frac{1}{|\mathbf{x}(\tau_2)|} \right\rangle_{\Omega,c}^{\mathbf{x}_0} = \frac{1}{a_{\tau_1\tau_2}^4(\mathbf{0})} - \frac{2}{\pi a_{\tau_1\tau_2}^4(\mathbf{0})} \arctan \sqrt{\frac{a_{\tau_1\tau_2}^2(\mathbf{0})}{a_{\tau_1\tau_2}(\mathbf{0})} - 1} - \frac{2}{\pi a_{\tau_1\tau_2}^2(\mathbf{0})}. \tag{5.305}$$

Inserting (5.303), setting $\tau_1 = 0$ and integrating over the imaginary times $\tau = \tau_2 \in [0, \hbar\beta]$, we find

$$\int_0^{\hbar\beta} d\tau \left\langle \frac{1}{|\mathbf{x}(\tau)|} \frac{1}{|\mathbf{x}(0)|} \right\rangle_{\Omega,c}^{\mathbf{x}_0} \approx_{\beta \rightarrow \infty} \frac{4M}{\hbar^2\beta\Omega} \left\{ e^{\hbar\beta\Omega} - 1 - \hbar\beta\Omega - \frac{\hbar^2\beta^2\Omega^2}{\pi} - \frac{2}{\pi} \times \left[e^{\hbar\beta\Omega} \arcsin \sqrt{1 - e^{-2\hbar\beta\Omega}} + \frac{1}{2} \ln \alpha(\beta) - \frac{1}{8} [\ln \alpha(\beta)]^2 - \frac{1}{2} \int_{\alpha(\beta)}^1 du \frac{\ln u}{1+u} \right] \right\}, \tag{5.306}$$

with the abbreviation

$$\alpha(\beta) = \frac{1 - \sqrt{1 - e^{-2\hbar\beta\Omega}}}{1 + \sqrt{1 - e^{-2\hbar\beta\Omega}}}. \tag{5.307}$$

Inserting this into (5.301) and going to the limit $\beta \rightarrow \infty$ we obtain

$$E_2^{(0)}(\Omega) = \lim_{\beta \rightarrow \infty} W_2^\Omega(\mathbf{0}) = \frac{9}{16}\hbar\Omega - \frac{3}{2\sqrt{\pi}}\sqrt{\frac{M\Omega}{\hbar}}e^2 - \frac{4}{\pi} \left(1 + \ln 2 - \frac{\pi}{2} \right) \frac{M}{\hbar^2}e^4. \tag{5.308}$$

Figure 5.26 Isotropic and anisotropic approximations to effective classical potential of Coulomb system in first and second order at temperature 0.1 in atomic units. The lowest line represents the high temperature limit in which all isotropic and anisotropic approximations coincide.

Postponing for a moment the extremization of (5.304) and (5.308) with respect to the trial frequency Ω , let us first rederive this result from a variational treatment of the ordinary Rayleigh-Schrödinger perturbation expansion for the ground state energy in Section 3.18. According to the replacement rule (5.186), we must first calculate the ground state energy for a Coulomb potential in the presence of a harmonic potential of frequency ω :

$$V(\mathbf{x}) = \frac{M}{2}\omega^2\mathbf{x}^2 - \frac{e^2}{|\mathbf{x}|}. \quad (5.309)$$

After this, we make the trivial replacement $\omega \rightarrow \sqrt{\Omega^2 + \omega^2 - \Omega^2}$ and re-expand the energy in powers of $\omega^2 - \Omega^2$, considering this quantity as being of the order e^2 and truncating the re-expansion accordingly. At the end we go to $\omega = 0$, since the original Coulomb system contains no oscillator potential. The result of this treatment will be precisely the expansions (5.304) and (5.308).

The Rayleigh-Schrödinger perturbation expansion of the ground state energy $E_N^{(0)}(\omega)$ for the potential (5.309) in Section 3.18 requires knowledge of the matrix elements of the Coulomb potential (5.288) with respect to the eigenfunctions of the harmonic oscillator with the frequency ω :

$$V_{n,l,m;n',l',m'} = \int_0^{2\pi} d\varphi \int_0^\pi d\vartheta \sin\vartheta \int_0^\infty dr r^2 \psi_{n,l,m}^*(r, \vartheta, \varphi) \frac{-e^2}{r} \psi_{n',l',m'}(r, \vartheta, \varphi), \quad (5.310)$$

where [see (9.67), (9.68), and (9.53)]

$$\begin{aligned} \psi_{n,l,m}(r, \vartheta, \varphi) &= \sqrt{\frac{2n!}{\Gamma(n+l+3/2)}}^4 \sqrt{\frac{M\omega}{\hbar}} \left(\frac{M\omega}{\hbar}r^2\right)^{(l+1)/2} \\ &\times L_n^{l+1/2}\left(\frac{M\omega}{\hbar}r^2\right) \exp\left\{-\frac{M\omega}{2\hbar}r^2\right\} Y_{l,m}(\vartheta, \varphi). \end{aligned} \quad (5.311)$$

Here n denotes the radial quantum number, $L_n^\alpha(x)$ the Laguerre polynomials and $Y_{l,m}(\vartheta, \varphi)$ the spherical harmonics obeying the orthonormality relation

$$\int_0^{2\pi} d\varphi \int_0^\pi d\vartheta \sin\vartheta Y_{l,m}^*(\vartheta, \varphi) Y_{l',m'}(\vartheta, \varphi) = \delta_{l,l'} \delta_{m,m'}. \quad (5.312)$$

Inserting (5.311) into (5.310), and evaluating the integrals, we find

$$\begin{aligned} V_{n,l,m;n',l',m'} &= -e^2 \sqrt{\frac{M\omega}{\pi\hbar}} \frac{\Gamma(l+1)\Gamma(n+1/2)}{\Gamma(l+3/2)} \sqrt{\frac{\Gamma(n'+l+3/2)}{n!n'\Gamma(n+l+3/2)}} \\ &\times {}_3F_2\left(-n', l+1, \frac{1}{2}; l+\frac{3}{2}, \frac{1}{2}-n; 1\right) \delta_{l,l'} \delta_{m,m'}, \end{aligned} \quad (5.313)$$

with the generalized hypergeometric series [compare (1.453)]

$${}_3F_2(\alpha_1, \alpha_2, \alpha_3; \beta_1, \beta_2; x) = \sum_{k=0}^{\infty} \frac{(\alpha_1)_k (\alpha_2)_k (\alpha_3)_k}{(\beta_1)_k (\beta_2)_k} \frac{x^k}{k!} \quad (5.314)$$

and the Pochhammer symbol $(\alpha)_k = \Gamma(\alpha+k)/\Gamma(\alpha)$.

These matrix elements are now inserted into the Rayleigh-Schrödinger perturbation expansion for the ground state energy

$$E^{(0)}(\omega) = E_{0,0,0} + V_{0,0,0;0,0,0} + \sum'_{n,l,m} \frac{V_{0,0,0;n,l,m} V_{n,l,m;0,0,0}}{E_{0,0,0} - E_{n,l,m}}$$

$$\begin{aligned}
& - \sum'_{n,l,m} V_{0,0,0;0,0,0} \frac{V_{0,0,0;n,l,m} V_{n,l,m;0,0,0}}{[E_{0,0,0} - E_{n,l,m}]^2} \\
& + \sum'_{n,l,m} \sum'_{n',l',m'} V_{0,0,0;n,l,m} V_{n,l,m;n',l',m'} V_{n',l',m';0,0,0} + \dots, \quad (5.315)
\end{aligned}$$

the denominators containing the energy eigenvalues of the harmonic oscillator

$$E_{n,l,m} = \hbar\omega \left(2n + l + \frac{3}{2} \right). \quad (5.316)$$

The primed sums in (5.315) run over all values of the quantum numbers $n, l = -\infty, \dots, +\infty$ and $m = -l, \dots, +l$, excluding those for which the denominators vanish. For the first three orders we obtain from (5.313)–(5.316)

$$E^{(0)}(\omega) = \frac{3}{2}\hbar\omega - \frac{2}{\sqrt{\pi}} \sqrt{\frac{M\omega}{\hbar}} e^2 - \frac{4}{\pi} \left(1 + \ln 2 - \frac{\pi}{2} \right) \frac{M}{\hbar^2} e^4 - c \sqrt{\frac{M^3}{\hbar^7 \omega}} e^6 + \dots, \quad (5.317)$$

with the constant

$$\begin{aligned}
c &= \frac{1}{\pi^{3/2}} \left\{ \sum_{n=1}^{\infty} \frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots 2n} \frac{1}{n^2 (n+1/2)} - \sum_{n=1}^{\infty} \sum_{n'=1}^{\infty} \frac{1 \cdot 3 \cdots (2n-1)}{2 \cdot 4 \cdots 2n} \right. \\
& \left. \times \frac{1 \cdot 3 \cdots (2n'-1)}{2 \cdot 4 \cdots 2n'} \frac{{}_3F_2 \left(-n', l+1, \frac{1}{2}; l+\frac{3}{2}, \frac{1}{2} - n; 1 \right)}{n n' (n+1/2)} \right\} \approx 0.031801. \quad (5.318)
\end{aligned}$$

Since we are interested only in the energies in the pure Coulomb system with $\omega = 0$, the variational re-expansion procedure described after (5.309) becomes particularly simple: We simply have to replace ω by $\sqrt{\Omega^2 - \Omega^2}$ which is appropriately re-expanded in the second Ω^2 , thereby considering Ω^2 as a quantity of order e^2 . For the first term in the energy (5.317) which is proportional to Ω itself this amounts to a multiplication by a factor $(1 - 1)^{1/2}$ which is re-expanded in the second “1” up to the third order as $1 - \frac{1}{2} - \frac{1}{8} - \frac{1}{16} = \frac{5}{16}$. The term $3\omega/2$ in (5.317) becomes therefore $15/32\omega$. By the same rule, the factor $\omega^{1/2}$ in the second term of the energy (5.317) goes over into $\Omega^{1/2}(1 - 1)^{1/4}$, re-expanded to second order in the second “1”, i.e., into $\Omega^{1/4}(1 - \frac{1}{4} - \frac{3}{32}) = \frac{21}{32}$. The next term in (5.317) happens to be independent of ω and needs no re-expansion, whereas the last term remains unchanged since it is already of highest order in e^2 . In this way we obtain from (5.317) the third-order variational perturbation expansion

$$E_3^{(0)}(\Omega) = \frac{15}{32}\hbar\Omega - \frac{21}{16\sqrt{\pi}} \sqrt{\frac{M\Omega}{\hbar}} e^2 - \frac{4}{\pi} \left(1 + \ln 2 - \frac{\pi}{2} \right) \frac{M}{\hbar^2} e^4 - c \sqrt{\frac{M^3}{\hbar^7 \Omega}} e^6. \quad (5.319)$$

Extremizing (5.304), (5.308), and (5.317) successively with respect to the trial frequency Ω we find to orders 1, 2, and 3 the optimal values

$$\Omega_1 = \Omega_2 = \frac{16}{9\pi} \frac{M e^4}{\hbar^3}, \quad \Omega_3 = c' \frac{M e^4}{\hbar^3}, \quad (5.320)$$

with $c' \approx 0.52621$. The corresponding approximations to the ground state energy are

$$E_N^{(0)}(\Omega^N) = -\gamma_N \frac{M e^4}{\hbar^2}, \quad (5.321)$$

with the constants

$$\gamma_1 = \frac{4}{3\pi} \approx 0.42441, \quad \gamma_2 = \frac{5 + 4 \ln 2}{\pi} - 2 \approx 0.47409, \quad \gamma_3 \approx 0.49012, \quad (5.322)$$

approaching exponentially fast the exact value $\gamma = 0.5$, as shown in Fig. 5.27.

Figure 5.27 Approach of the variational approximations of first, second, and third order to the correct ground state energy -0.5 , in atomic units.

5.22 Polarons

An important role in the development of variational methods for the approximate solution of path integrals was played by the *polaron* problem [34]. Polarons arise when electrons travel through ionic crystals thereby producing an electrostatic deformation in their neighborhood. If $\mathbf{P}^i(\mathbf{x}, t)$ denotes electric polarization density caused by the displacement of the positive against the negative ions, an electron sees a local ionic charge distribution

$$\rho^i(\mathbf{x}, t) = \nabla \cdot \mathbf{P}^i(\mathbf{x}, t), \quad (5.323)$$

which gives rise to an electric potential satisfying

$$\nabla^2 A^0(\mathbf{x}, t) = 4\pi \nabla \cdot \mathbf{P}^i(\mathbf{x}, t). \quad (5.324)$$

The Fourier transform of this,

$$A_{\mathbf{k}}^0(t) \equiv \int_{-\infty}^{\infty} d^3x A^0(\mathbf{x}, t) e^{-i\mathbf{k}\mathbf{x}}, \quad (5.325)$$

and that of $\mathbf{P}^i(\mathbf{x}, t)$,

$$\mathbf{P}_{\mathbf{k}}^i(t) = \int_{-\infty}^{\infty} d^3x \mathbf{P}^i(\mathbf{x}, t) e^{-i\mathbf{k}\mathbf{x}}, \quad (5.326)$$

are related by

$$A_{\mathbf{k}}^0(t) = -\frac{4\pi}{k^2} i\mathbf{k} \cdot \mathbf{P}_{\mathbf{k}}^i(t). \quad (5.327)$$

Only longitudinal phonons which have $\mathbf{P}_{\mathbf{k}}^i(t) \propto \mathbf{k}$ and correspond to density fluctuations in the crystal contribute. For these, an electron at position $\mathbf{x}(t)$ experiences an electric potential

$$A^0(\mathbf{x}, t) = -\sum_{\mathbf{k}} A_{\mathbf{k}}^0(t) \frac{e^{i\mathbf{k}\mathbf{x}}}{\sqrt{V}} = i \sum_{\mathbf{k}} \frac{4\pi}{|\mathbf{k}|} \mathbf{P}_{\mathbf{k}}^i(\tau) \frac{e^{i\mathbf{k}\mathbf{x}}}{\sqrt{V}}. \quad (5.328)$$

In the regime of optical phonons, each Fourier component oscillates with approximately the same frequency ω , the frequency of longitudinal optical phonons. The variables $\mathbf{P}_{\mathbf{k}}^i(t)$ have therefore a Lagrangian

$$L(t) = \frac{1}{2\mu} \sum_{\mathbf{k}} \left[\dot{\mathbf{P}}_{-\mathbf{k}}^i(t) \dot{\mathbf{P}}_{\mathbf{k}}^i(t) - \omega^2 \mathbf{P}_{-\mathbf{k}}^i(t) \mathbf{P}_{\mathbf{k}}^i(t) \right], \quad (5.329)$$

with some material constant μ and $\mathbf{P}_{-\mathbf{k}}^i(t) = \mathbf{P}_{\mathbf{k}}^{i*}(t)$, since the polarization is a real field. This can be expressed in terms of measurable properties of the crystal. For this we note that the interaction of the polarization field with a given total charge distribution $\rho(\mathbf{x}, t)$ is described by a Lagrangian

$$L_{\text{int}}(t) = - \int d^3x \rho(\mathbf{x}, t) V(\mathbf{x}, t). \quad (5.330)$$

Inserting (5.325) and performing a partial

$$L_{\text{int}}(t) = 4\pi \int d^3x \frac{1}{\nabla^2} \nabla \rho(\mathbf{x}, t) \cdot \mathbf{P}^i(\mathbf{x}', t). \quad (5.331)$$

Recalling the Gauss law $\nabla \cdot \mathbf{D}(\mathbf{x}, t) = 4\pi\rho(\mathbf{x}, t)$ we identify the factor of $\mathbf{P}^i(\mathbf{x}, t)$ with the total electric displacement field and write

$$L_{\text{int}}(t) = 4\pi \int d^3x \mathbf{D}(\mathbf{x}, t) \cdot \mathbf{P}^i(\mathbf{x}, t). \quad (5.332)$$

In combination with (5.329) this leads to an equation of motion

$$\frac{1}{\mu} [\ddot{\mathbf{P}}_{\mathbf{k}}^i(t) + \omega^2 \mathbf{P}_{\mathbf{k}}^i(t)] = \mathbf{D}_{\mathbf{k}}(t). \quad (5.333)$$

If we go over to the temporal Fourier components $\mathbf{P}_{\omega', \mathbf{k}}^i$ of the ionic polarization, we find the relation

$$\frac{1}{\mu} (\omega^2 - \omega'^2) \mathbf{P}_{\omega', \mathbf{k}}^i = \mathbf{D}_{\omega', \mathbf{k}}. \quad (5.334)$$

For very slow deformations, this becomes

$$\frac{\omega^2}{\mu} \mathbf{P}_{\omega', \mathbf{k}}^i \approx \mathbf{D}_{0, \mathbf{k}}. \quad (5.335)$$

Using the general relation

$$\mathbf{D}_{\omega', \mathbf{k}} = \mathbf{E}_{\omega', \mathbf{k}} + 4\pi \mathbf{P}_{\omega', \mathbf{k}}, \quad (5.336)$$

where $4\pi \mathbf{P}_{\omega', \mathbf{k}}$ contains both ionic *and* electronic polarizations, we obtain

$$4\pi \mathbf{P}_{\omega', \mathbf{k}} = \left(1 - \frac{1}{\epsilon_{\omega'}}\right) \mathbf{D}_{\omega', \mathbf{k}}, \quad (5.337)$$

with $\epsilon_{\omega'}$ being the dielectric constant at frequency ω' . For a slowly moving electron, the lattice deformations have small frequencies, and we can write the time-dependent equation

$$4\pi \mathbf{P}_{\mathbf{k}}(t) \approx \left(1 - \frac{1}{\epsilon_0}\right) \mathbf{D}_{\mathbf{k}}(t). \quad (5.338)$$

By comparison with Eq. (5.335) we determine the parameter μ . Before we can do so, however, we must subtract from (5.338) the contribution of the electrons. These fulfill the approximate time-dependent equation

$$4\pi\mathbf{P}_{\mathbf{k}}^{\text{el}}(t) \approx \left(1 - \frac{1}{\epsilon_{\infty}}\right) \mathbf{D}_{\mathbf{k}}(t), \quad (5.339)$$

where ϵ_{∞} is the dielectric constant at high frequency where only electrons can follow the field oscillations. The purely ionic polarization field is therefore given by

$$4\pi\mathbf{P}_{\mathbf{k}}^{\text{i}}(t) \approx \left(\frac{1}{\epsilon_{\infty}} - \frac{1}{\epsilon_0}\right) \mathbf{D}_{\mathbf{k}}(t). \quad (5.340)$$

By comparison with (5.334) we identify

$$\mu \approx \frac{\omega^2}{4\pi} \left(\frac{1}{\epsilon_{\infty}} - \frac{1}{\epsilon_0}\right). \quad (5.341)$$

5.22.1 Partition Function

The partition function of the combined system of an electron and the oscillating polarization is therefore described by the imaginary-time path integral

$$Z = \int \mathcal{D}^3x \prod_{\mathbf{k}} \int \mathcal{D}^3\mathbf{P}_{\mathbf{k}} \exp \left(-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left\{ \frac{M}{2} \dot{\mathbf{x}}^2(\tau) + \sum_{\mathbf{k}} \frac{1}{2\mu} \left[\dot{\mathbf{P}}_{-\mathbf{k}}^{\text{i}}(t) \dot{\mathbf{P}}_{\mathbf{k}}^{\text{i}}(t) - \omega^2 \mathbf{P}_{-\mathbf{k}}^{\text{i}}(t) \mathbf{P}_{\mathbf{k}}^{\text{i}}(t) \right] + ie \sum_{\mathbf{k}} \frac{4\pi}{|\mathbf{k}|} \mathbf{P}_{\mathbf{k}}(\tau) \frac{e^{i\mathbf{k}\mathbf{x}(\tau)}}{\sqrt{V}} \right\} \right), \quad (5.342)$$

where V is the volume of the system. The path integral is Gaussian in the Fourier components $\mathbf{P}_{\mathbf{k}}(\tau)$. These can therefore be integrated out with the rules of Subsection 3.8.2. For the correlation function of the polarizations we shall use the representation of the Green function (3.251) as a sum of periodic repetitions of the zero-temperature Green function

$$\langle \mathbf{P}_{\mathbf{k}}(\tau) \mathbf{P}_{-\mathbf{k}}(\tau) \rangle = \frac{\hbar}{2\omega} \sum_{n=-\infty}^{\infty} e^{-\omega|\tau-\tau'+n\hbar\beta|}. \quad (5.343)$$

Abbreviating

$$\sum_{n=-\infty}^{\infty} e^{-\omega|\tau-\tau'+n\hbar\beta|} \equiv e_{\text{per}}^{-\omega|\tau-\tau'|} = \frac{1}{2\omega} \left(e^{-\omega|\tau-\tau'|} - e^{-\omega(\hbar\beta-|\tau-\tau'|)} \right) \frac{1}{1 - e^{-\hbar\beta\omega}}, \quad (5.344)$$

the right-hand side being valid for $\hbar\beta > \tau, \tau' > 0$, we find

$$Z = \int \mathcal{D}^3x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \frac{M}{2} \dot{\mathbf{x}}^2(\tau) + \frac{\mu}{2\hbar^2} 4\pi e^2 \frac{\hbar}{2\omega} \frac{1}{V} \sum_{\mathbf{k}} \frac{4\pi}{\mathbf{k}^2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' e^{i\mathbf{k}[\mathbf{x}(\tau)-\mathbf{x}(\tau')]} e_{\text{per}}^{-\omega|\tau-\tau'|} \right\}. \quad (5.345)$$

Performing the sum over all wave vectors \mathbf{k} using the formula

$$\frac{1}{V} \sum_{\mathbf{k}} \frac{4\pi}{\mathbf{k}^2} e^{i\mathbf{k}\mathbf{x}} = \frac{1}{|\mathbf{x}|}, \quad (5.346)$$

we obtain the path integral

$$Z = \int \mathcal{D}^3x \exp \left\{ -\frac{1}{\hbar} \left[\int_0^{\hbar\beta} d\tau \frac{M}{2} \dot{\mathbf{x}}^2(\tau) - \frac{a}{2\sqrt{2}} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \frac{e^{-\omega|\tau-\tau'|}}{|\mathbf{x}(\tau) - \mathbf{x}(\tau')|} \right] \right\}, \quad (5.347)$$

where

$$a \equiv \frac{\mu}{\hbar} 4\pi e^2 \frac{\hbar}{2\omega} \sqrt{2}. \quad (5.348)$$

The factor $\sqrt{2}$ is a matter of historic convention. Staying with this convention, we use the characteristic length scale (9.73) associated with the mass M and the frequency ω :

$$\lambda_\omega \equiv \sqrt{\frac{\hbar}{M\omega}}. \quad (5.349)$$

This length scale will appear in the wave functions of the harmonic oscillator in Eq. (9.73). Using this we introduce a dimensionless coupling constant α defined by

$$\alpha \equiv \frac{1}{\sqrt{2}} \left(\frac{1}{\epsilon_\omega} - \frac{1}{\epsilon_0} \right) \frac{e^2}{\hbar\omega\lambda_\omega}. \quad (5.350)$$

A typical value of α is 5 for sodium chloride. In different crystals it varies between 1 and 20, thus requiring a strong-coupling treatment. In terms of α , one has

$$a = \hbar\omega^2 \lambda_\omega \alpha. \quad (5.351)$$

The expression (5.348) is the famous path integral of the polaron problem written down in 1955 by Feynman [20] and solved approximately by a variational perturbation approach.

In order to allow for later calculations of a particle density in an external potential, we decompose the paths in a Fourier series with fixed endpoints $\mathbf{x}(\beta) \equiv \mathbf{x}_b = \mathbf{x}_a$:

$$\mathbf{x}(\tau) = \mathbf{x}_a + \sum_{n=1}^{\infty} \mathbf{x}_n \sin \nu_n \tau, \quad \nu_n \equiv n\pi/\hbar\beta. \quad (5.352)$$

The path integral is then the limit $N \rightarrow \infty$ of the product of integrals

$$\int \mathcal{D}^3x \equiv \int \frac{d^2x_a}{\sqrt{2\pi\hbar^2\beta/M}} \prod_{n=1}^{\infty} \left[\int \frac{d^3x_n}{\sqrt{4\pi/M\nu_n^2\beta}} \right]. \quad (5.353)$$

The correctness of this measure is verified by considering the free particle in which case the action is

$$\mathcal{A}_0 = \frac{1}{2} \sum_{n=1}^{\infty} A_n^0 \mathbf{x}_n^2, \quad \text{with} \quad A_n^0 \equiv \frac{M}{2} \hbar\beta \nu_n^2. \quad (5.354)$$

The Fourier components \mathbf{x}_n can be integrated leaving a final integral

$$Z = \int \frac{d^2 x_a}{\sqrt{2\pi\hbar^2\beta/M}^3}, \quad (5.355)$$

which is the correct partition function of a free particle [compare with the one-dimensional expression (3.811)].

The endpoints $\mathbf{x}_b = \mathbf{x}_a$ do not appear in the integrand of (5.347) as a manifestation of translational invariance. The integral over the endpoints produces therefore a total volume factor V . We may imagine performing the path integral with fixed endpoints which produces the particle density.

5.22.2 Harmonic Trial System

The harmonic trial system used by Feynman as a starting point of his variational treatment has the generating functional

$$Z^{\Omega,C}[\mathbf{j}] = \int \mathcal{D}^3 x \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{M}{2} \dot{\mathbf{x}}^2(\tau) - \mathbf{j}(\tau) \mathbf{x}(\tau) \right] - \frac{C}{2} \frac{M}{\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' [\mathbf{x}(\tau) - \mathbf{x}(\tau')]^2 e_{\text{per}}^{-\Omega|\tau-\tau'|} \right\}. \quad (5.356)$$

The external current is Fourier-decomposed in the same way as $\mathbf{x}(\tau)$ in (5.352). To preserve translational invariance, we assume the current to vanish at the endpoints: $\mathbf{j}_a = 0$. Then the first two terms in the action in (5.356) are

$$\mathcal{A}[\mathbf{j}] = \frac{1}{2} \sum_{n=1}^{\infty} (A_n^0 \mathbf{x}_n^2 - \beta \mathbf{j}_n \mathbf{x}_n). \quad (5.357)$$

The Fourier decomposition of the double integral in (5.356) reads

$$\int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \left[\sum_{n=1}^{\infty} (\sin \nu_n \tau - \sin \nu_n \tau') \mathbf{x}_n \right]^2 e_{\text{per}}^{-\Omega|\tau-\tau'|}. \quad (5.358)$$

With the help of trigonometric identities and a change of variables to $\sigma = (\tau + \tau')/2$ and $\Delta\tau = (\tau - \tau')/2$, this becomes

$$2 \int_0^{\hbar\beta} d\sigma \int_0^{2\hbar\beta} d\Delta\tau \left[\sum_{n=1}^{\infty} \cos \nu_n \sigma \sin(\nu_n \Delta\tau/2) \mathbf{x}_n \right]^2 e_{\text{per}}^{-\Omega|\Delta\tau|}. \quad (5.359)$$

Integrating out σ leaves

$$\hbar\beta \int_0^{2\hbar\beta} d\Delta\tau \sum_{n=1}^{\infty} \sin^2(\nu_n \Delta\tau/2) \mathbf{x}_n^2 e_{\text{per}}^{-\Omega|\Delta\tau|}, \quad (5.360)$$

and performing the integral over $\delta\tau$ gives for (5.358) the result

$$\frac{\hbar\beta}{2} \left(1 - e^{-2\hbar\beta\Omega}\right) \left(1 + 2 \sum_{n'=1}^{\infty} e^{-n'\hbar\beta\Omega}\right) \sum_{n=1}^{\infty} \mathbf{x}_n^2 \frac{\nu_n^2}{\nu_n^2 + \Omega^2}. \quad (5.361)$$

Hence we can write the interaction term in (5.356) as

$$-\frac{C_\beta M\beta}{4\Omega} \sum_{n=1}^{\infty} \mathbf{x}_n^2 \frac{\nu_n^2}{\nu_n^2 + \Omega^2}, \quad C_\beta \equiv C \left(1 - e^{-2\hbar\beta\Omega}\right) \coth \frac{\hbar\beta\Omega}{2}. \quad (5.362)$$

This changes A_n^0 in (5.357) into

$$A_n \equiv \frac{M\hbar\beta\nu_n^2}{2} \left(1 + \frac{C_\beta}{\Omega} \frac{1}{\nu_n^2 + \Omega^2}\right) = A_n^0 \left(1 + \frac{C_\beta}{\Omega} \frac{1}{\nu_n^2 + \Omega^2}\right). \quad (5.363)$$

The trial partition function without external source is then approximately equal to

$$Z^{\Omega,C} \underset{T \approx 0}{\equiv} \int \mathcal{D}^3x \int \frac{d^2x_a}{\sqrt{2\pi\hbar^2\beta/M}}^3 \prod_{n=1}^{\infty} \sqrt{\frac{A_n^0}{A_n}}. \quad (5.364)$$

The product is calculated as follows:

$$\prod_{n=1}^{\infty} \sqrt{\frac{A_n^0}{A_n}} = \prod_{n=1}^{\infty} \sqrt{1 + \frac{C_\beta}{\Omega} \frac{1}{\nu_n^2 + \Omega^2}}^{-3} = e^{-\beta F^{\Omega,C}}, \quad (5.365)$$

resulting in the approximate free energy

$$F^{\Omega,C} \underset{T \approx 0}{=} \frac{1}{\beta} \sum_{n=1}^{\infty} \log \frac{\nu_n^2 + \Gamma_\beta^2}{\nu_n^2 + \Omega^2}, \quad (5.366)$$

where we have introduced the function of the trial frequency Ω :

$$\Gamma_\beta^2(\Omega) \equiv \Omega^2 + C_\beta/\Omega. \quad (5.367)$$

With the help of formula (2.173) we find therefore

$$F^{\Omega,C} = \frac{3}{2\beta} \log \frac{\sinh \hbar\beta\Gamma_\beta}{\sinh \hbar\beta\Omega}. \quad (5.368)$$

For simplicity, we shall from now on consider only the low-temperature regime where $C_\beta \gg C$, $\Gamma_\beta \rightarrow \Omega^2 + C/\Omega$, and the free energy (5.368) becomes approximately

$$F^{\Omega,C} \underset{T \approx 0}{=} \frac{3\hbar}{2} (\Gamma - \Omega) \equiv E_0^{\Omega,C}. \quad (5.369)$$

The right-hand side is the ground state energy of the harmonic trial system (5.356).

In Feynman's variational approach, the ground state energy of the polaron is smaller than this given by the minimum of [compare (5.18), (5.32) and (5.45)]

$$E_0 \leq E_0^{\Omega,C} + \Delta E_{\text{int}}^{\Omega,C} - \Delta E_{\text{int,harm}}^{\Omega,C}, \quad (5.370)$$

where the two additional terms are the limits $\beta \rightarrow \infty$ of the harmonic expectation values

$$\Delta E_{\text{int}}^{\Omega,C} = -\frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int}} \rangle^{\Omega,C} \equiv \frac{1}{\hbar\beta} \left\langle -\frac{a}{2\sqrt{2}} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \frac{e^{-\omega|\tau-\tau'|}}{|\mathbf{x}(\tau) - \mathbf{x}(\tau')|} \right\rangle^{\Omega,C}, \quad (5.371)$$

and

$$\Delta E_{\text{int,harm}}^{\Omega,C} = -\frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int,harm}} \rangle^{\Omega,C} \equiv \frac{1}{\hbar\beta} \left\langle \frac{C}{2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' [\mathbf{x}(\tau) - \mathbf{x}(\tau')]^2 e^{-\Omega|\tau-\tau'|} \right\rangle^{\Omega,C}. \quad (5.372)$$

The calculation of the first expectation value is most easily done using the Fourier decomposition (5.345), where we must find the expectation value

$$\left\langle e^{i\mathbf{k}[\mathbf{x}(\tau) - \mathbf{x}(\tau')]} \right\rangle^{\Omega,C}. \quad (5.373)$$

In the trial path integral (5.356), the exponential corresponds to a source

$$\mathbf{j}(\tau'') = \hbar\mathbf{k} \left[\delta^{(3)}(\tau - \tau'') - \delta^{(3)}(\tau' - \tau'') \right], \quad (5.374)$$

in terms of which (5.373) reads

$$\left\langle e^{i \int d\tau \mathbf{j}(\tau) \mathbf{x}(\tau) / \hbar} \right\rangle^{\Omega,C}. \quad (5.375)$$

Introducing the correlation function

$$\langle x_i(\tau) x_j(\tau') \rangle^{\Omega,C} \equiv \delta_{ij} G^{\Omega,\Gamma}(\tau, \tau'), \quad (5.376)$$

and using Wick's rule (3.309) for harmonically fluctuating paths, the expectation value (5.375) is equal to

$$\left\langle e^{i \int d\tau \mathbf{j}(\tau) \mathbf{x}(\tau) / \hbar} \right\rangle^{\Omega,C} = \exp \left\{ -\frac{1}{2\hbar^2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \mathbf{j}(\tau) G^{\Omega,\Gamma}(\tau, \tau') \mathbf{j}(\tau') \right\}. \quad (5.377)$$

Inserting the special source (5.373), we obtain

$$\left\langle e^{i\mathbf{k}[\mathbf{x}(\tau) - \mathbf{x}(\tau')]} \right\rangle^{\Omega,C} = I^{\Omega,C}(\mathbf{k}, \tau, \tau') \equiv \exp \left[\mathbf{k}^2 \bar{G}^{\Omega,\Gamma}(\tau, \tau') \right], \quad (5.378)$$

where the exponent contains the subtracted Green function

$$\bar{G}^{\Omega,\Gamma}(\tau, \tau') \equiv G^{\Omega,\Gamma}(\tau, \tau') - \frac{1}{2} G^{\Omega,\Gamma}(\tau, \tau) - \frac{1}{2} G^{\Omega,\Gamma}(\tau', \tau'). \quad (5.379)$$

The Green function $G^{\Omega,\Gamma}(\tau, \tau')$ itself has the Fourier expansion

$$G^{\Omega,\Gamma}(\tau, \tau') = \hbar \sum_{n=1}^{\infty} \frac{\sin \nu_n \tau \sin \nu_n \tau'}{2A_n/\hbar\beta} = \frac{\hbar}{M} \sum_{n=1}^{\infty} \frac{\nu_n^2 + \Omega^2}{\nu_n^2(\nu_n^2 + \Gamma_\beta^2)} \sin \nu_n \tau \sin \nu_n \tau'. \quad (5.380)$$

It solves the Euler-Lagrange equation which extremizes the action in (5.356) for a source $\mathbf{j}(\tau) = M\delta(\tau - \tau')$:

$$\left\{ -\partial_\tau^2 + 2C \int_0^{\hbar\beta} d\tau' [x_i(\tau) - x_i(\tau')] e^{-\Omega|\tau-\tau'|} \right\} G^{\Omega,\Gamma}(\tau, \tau') = \delta(\tau - \tau'). \quad (5.381)$$

Decomposing

$$\frac{\nu_n^2 + \Omega^2}{\nu_n^2(\nu_n^2 + \Gamma_\beta^2)} = \frac{\Omega^2}{\Gamma_\beta^2} \times \frac{1}{\nu_n^2} + \frac{\Gamma_\beta^2 - \Omega^2}{\Gamma_\beta^2} \times \frac{1}{\nu_n^2 + \Gamma_\beta^2}, \quad (5.382)$$

we obtain a combination of ordinary Green functions of the second-order operator differential equation (3.239), but with Dirichlet boundary conditions. For such Green functions, the spectral sum over n was calculated in Section 3.4 for real time [see (3.36) and (3.145)]. The imaginary-time result is

$$G_{\omega^2}(\tau, \tau') = \sum_{n=1}^{\infty} \frac{\sin \nu_n \tau \sin \nu_n \tau'}{\nu_n^2 + \omega^2} = \frac{\sinh \omega(\hbar\beta - \tau) \sinh \omega \tau'}{\omega \sinh \omega \hbar\beta}, \quad \text{for } \tau > \tau' > 0. \quad (5.383)$$

In the low-temperature limit, this becomes

$$G_{\omega^2}(\tau, \tau') = \frac{1}{2\omega} \left(e^{-\omega(\tau-\tau')} - e^{-\omega(\tau+\tau')} \right), \quad \text{for } \tau > \tau' > 0, \quad (5.384)$$

such that

$$\bar{G}_{\Gamma^2}(\tau, \tau') = \frac{1}{2\Gamma} \left(e^{-\Gamma(\tau-\tau')} - 1 - e^{-\Gamma(\tau+\tau')} + \frac{1}{2}e^{-2\Gamma\tau} + \frac{1}{2}e^{-2\Gamma\tau'} \right), \quad \text{for } \tau > \tau' > 0. \quad (5.385)$$

In the limit $\Gamma \rightarrow 0$, this becomes $-\frac{1}{2}|\tau - \tau'|$. We therefore obtain at zero temperature

$$\begin{aligned} \bar{G}^{\Omega,\Gamma}(\tau, \tau') &\stackrel{\Gamma \rightarrow 0}{=} \frac{\hbar}{2M} \left[\frac{\Omega^2}{\Gamma^2} \bar{G}_0(\tau, \tau') + \frac{\Gamma^2 - \Omega^2}{\Gamma^2} \bar{G}_0(\tau, \tau') \right] \\ &= -\frac{\hbar}{2M} \left\{ \frac{\Omega^2}{\Gamma^2} |\tau - \tau'| + \frac{\Gamma^2 - \Omega^2}{\Gamma^3} \left(1 - e^{-\Gamma|\tau-\tau'|} + e^{-\Gamma(\tau+\tau')} - \frac{1}{2}e^{-2\Gamma\tau} - \frac{1}{2}e^{-2\Gamma\tau'} \right) \right\}, \end{aligned} \quad (5.386)$$

to be inserted into (5.378) to get the expectation value $\langle e^{i\mathbf{k}[\mathbf{x}(\tau) - \mathbf{x}(\tau')]} \rangle$. The last three terms can be avoided by shifting the time interval under consideration and thus the Fourier expansion (5.352) from $(0, \hbar\beta)$ to $(-\hbar\beta/2, \hbar\beta/2)$, which changes Green function (5.387) to

$$\begin{aligned} G_{\omega^2}(\tau, \tau') &= \sum_{n=1}^{\infty} \frac{\sin \nu_n(\tau + \hbar\beta/2) \sin \nu_n(\tau' + \hbar\beta/2)}{\nu_n^2 + \omega^2} \\ &= \frac{\sinh \omega(\hbar\beta/2 - \tau) \sinh \omega(\tau' + \hbar\beta/2)}{\omega \sinh \omega \hbar\beta}, \quad \text{for } \tau > \tau' > 0. \end{aligned} \quad (5.387)$$

We have seen before at the end of Section 3.20 that such a shift is important when discussing the limit $T \rightarrow 0$ which we want to do in the sequel. With the symmetric limits of integration, the Green function (5.384) loses its last term [compare with (3.147) for real times] and (5.386) simplifies to

$$\bar{G}^{\Omega,\Gamma}(\tau, \tau') \underset{T=0}{\approx} -\frac{\hbar}{2M} \left\{ \frac{\Omega^2}{\Gamma^2} |\tau - \tau'| + \frac{\Gamma^2 - \Omega^2}{\Gamma^3} (1 - e^{-\Gamma|\tau - \tau'|}) \right\}. \quad (5.388)$$

At any temperature, we have the complicated expression for $\tau > \tau'$:

$$\begin{aligned} \bar{G}^{\Omega,\Gamma}(\tau, \tau') = & -\frac{\hbar}{2M} \left\{ \frac{\Omega^2}{\Gamma_\beta^2} \left[\tau - \tau' - \frac{1}{\hbar\beta} (\tau - \tau')^2 \right] \right. \\ & \left. - \frac{\Gamma_\beta^2 - \Omega^2}{\Gamma_\beta^2 \sinh \hbar\beta\Gamma_\beta} [\sinh \Gamma_\beta(\hbar\beta/2 - \tau) \sinh \Gamma_\beta(\tau' + \hbar\beta/2) - (\tau' \rightarrow \tau) - (\tau \rightarrow \tau')] \right\}. \end{aligned} \quad (5.389)$$

With the help of the Fourier integral (5.346) we find from this the expectation value of the interaction in (5.347):

$$\left\langle \frac{1}{|\mathbf{x}(\tau) - \mathbf{x}(\tau')|} \right\rangle = \int \frac{d^3k}{(2\pi)^3} \frac{4\pi}{\mathbf{k}^2} \langle e^{i\mathbf{k}[\mathbf{x}(\tau) - \mathbf{x}(\tau')]} \rangle = \int \frac{d^3k}{(2\pi)^3} \frac{4\pi}{\mathbf{k}^2} I^{\Omega,C}(\mathbf{k}, \tau, \tau'). \quad (5.390)$$

For zero temperature, this leads directly to the expectation value of the interaction in (5.347):

$$\begin{aligned} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \left\langle \frac{e^{-\omega|\tau - \tau'|}}{|\mathbf{x}(\tau) - \mathbf{x}(\tau')|} \right\rangle & \approx 2\hbar\beta \int_0^{\hbar\beta/2} d\Delta\tau e^{-\omega\Delta\tau} \int \frac{d^3k}{(2\pi)^3} \frac{4\pi}{\mathbf{k}^2} e^{\mathbf{k}^2 \bar{G}^{\Omega,\Gamma}(\Delta\tau, 0)} \\ & \approx 4 \frac{\hbar\beta}{\sqrt{2\pi\omega\lambda_\omega}} \int_0^\infty d\Delta\tau \frac{e^{-\omega\Delta\tau}}{\sqrt{-2\bar{G}^{\Omega,\Gamma}(\Delta\tau, 0)}}. \end{aligned} \quad (5.391)$$

The expectation value of the harmonic trial interaction in (5.356), on the other hand, is simply found from the correlation function (5.376) [or equivalently from the second derivative of $I^{\Omega,C}(\mathbf{k}, \tau, \tau')$ with respect to the momenta]:

$$\langle [\mathbf{x}(\tau) - \mathbf{x}(\tau')]^2 \rangle^{\Omega,C} = -6\bar{G}^{\Omega,\Gamma}(\tau, \tau'). \quad (5.392)$$

At low temperatures, this leads to an integral

$$\frac{CM}{2\hbar} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' \langle [\mathbf{x}(\tau) - \mathbf{x}(\tau')]^2 \rangle^{\Omega,C} e_{\text{per}}^{-\Omega|\tau - \tau'|} \underset{T=0}{=} \hbar\beta \frac{3C}{4\Omega\Gamma}. \quad (5.393)$$

This expectation value contributes to the ground state energy a term

$$\Delta E_{\text{int, var}}^{\Omega,C} = \frac{3\hbar C}{4\Omega\Gamma}. \quad (5.394)$$

Note that this term can be derived from the derivative of the ground state energy (5.368) as $C\partial_C E_0^{\Omega,C}$. Together with $-a/2\sqrt{2}$ times the result of (5.391), the inequality (5.370) for the ground state energy becomes

$$E_0 \leq \frac{3\hbar}{4\Gamma} (\Gamma - \Omega)^2 - \hbar\omega \frac{\alpha\omega}{\sqrt{\pi\omega}} \int_0^\infty d\Delta\tau \frac{e^{-\omega\Delta\tau}}{\sqrt{-2\tilde{G}^{\Omega,\Gamma}(\Delta\tau, 0)}}. \quad (5.395)$$

This has to be minimized in Ω and C , or equivalently, in Ω and Γ . Considering the low-temperature limit, we have taken the upper limit of integration to infinity (the frequency ω corresponds usually to temperatures of the order of 1000 K).

For small α , the optimal parameters Ω and Γ differ by terms of order α . We can therefore expand the integral in (5.395) and find that the minimum lies, in natural units with $\hbar = \omega = 1$, at $\Omega = 3$ and $\Gamma = 3[1 + 2\alpha(1 - P)/3\Gamma]$, where $P = 2[(1 - \Gamma)^{1/2} - 1]$. From this we obtain the upper bound

$$E_0 \leq -\alpha - \frac{\alpha^2}{81} + \dots \approx -\alpha - 0.0123\alpha^2 + \dots \quad (5.396)$$

This agrees well with the perturbative result [21]

$$E_w^{\text{ex}} = -\alpha - 0.0159196220\alpha^2 - 0.000806070048\alpha^3 - O(\alpha^4). \quad (5.397)$$

The second term has the exact value

$$\left[\frac{1}{\sqrt{2}} - \log\left(1 + 3\sqrt{2}/4\right) \right] \alpha^2. \quad (5.398)$$

In the strong-coupling region, the best parameters are $\Omega = 1$, $\Gamma = 4\alpha^2/9\pi - [4(\log 2 + \gamma/2) - 1]$, where $\gamma \approx 0.5773156649$ is the Euler-Mascheroni constant (2.469). At these values, we obtain the upper bound

$$E_0 \leq -\frac{\alpha^2}{3\pi} - 3\left(\frac{1}{4} + \log 2\right) + O(\alpha^{-2}) \approx -0.1061\alpha - 2.8294 + O(\alpha^{-2}). \quad (5.399)$$

This agrees reasonably well with the precise strong-coupling expansion [23].

$$E_s^{\text{ex}} = -0.108513\alpha^2 - 2.836 - O(\alpha^{-2}). \quad (5.400)$$

The numerical results for variational parameters and energy are shown in Table 5.12.

5.22.3 Effective Mass

By performing a shift in the velocity of the path integral (5.347), Feynman calculated also an effective mass for the polaron. The result is

$$M^{\text{eff}} = M \left[1 + \frac{\alpha}{3} \frac{\omega}{\sqrt{\pi\omega}} \Gamma^2 \int_0^\infty d\Delta\tau \frac{(\Delta\tau)^2 e^{-\omega\Delta\tau}}{\sqrt{-2\tilde{G}^{\Omega,\Gamma}(\Delta\tau, 0)}} \right]. \quad (5.401)$$

Table 5.12 Numerical results for variational parameters and energy.

α	Γ	Ω	E_0	$\Delta E_0^{(2)}$	E_{tot}	correction
1	3.110	2.871	-1.01	-0.0035	-1.02	0.35 %
3	3.421	2.560	-3.13	-0.031	-3.16	1.0 %
5	4.034	2.140	-5.44	-0.083	-5.52	1.5 %
7	5.810	1.604	-8.11	-0.13	-8.24	1.6 %
9	9.850	1.282	-11.5	-0.17	-11.7	1.4 %
11	15.41	1.162	-15.7	-0.22	-15.9	1.4 %
15	30.08	1.076	-26.7	-0.39	-27.1	1.5 %

The reduced effective mass $m \equiv M^{\text{eff}}/M$ has the weak-coupling expansion

$$m_w = 1 + \frac{\alpha}{6} + 2.469136 \times 10^{-2} \alpha^2 + 3.566719 \times 10^{-3} \alpha^3 + \dots \quad (5.402)$$

and behaves for strong couplings like

$$\begin{aligned} m_s &\approx \frac{16}{81\pi^2} \alpha^4 - \frac{4}{3\pi} (1 + \log 4) \alpha^2 + 11.85579 + \dots \\ &\approx 0.020141 \alpha^4 - 1.012775 \alpha^2 + 11.85579 + \dots \end{aligned} \quad (5.403)$$

The exact expansions are [31]

$$m_w^{\text{ex}} = 1 + \frac{\alpha}{6} + 2.362763 \times 10^{-2} \alpha^2 + O(\alpha^4), \quad (5.404)$$

$$m_s^{\text{ex}} = 0.0227019 \alpha^4 + O(\alpha^2). \quad (5.405)$$

5.22.4 Second-Order Correction

With some effort, also the second-order contribution to the variational energy has been calculated at zero temperature [32]. It gives a contribution to the ground state energy

$$\Delta E_0^{(2)} = -\frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\langle (\mathcal{A}_{\text{int}} - \mathcal{A}_{\text{int,harm}})^2 \right\rangle_c^{\Omega,C}. \quad (5.406)$$

Recall the definitions of the interactions in Eqs. (5.371) and (5.372). There are three terms

$$\Delta E_0^{(2,1)} = -\frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\{ \left\langle \mathcal{A}_{\text{int}}^2 \right\rangle^{\Omega,C} - \left[\left\langle \mathcal{A}_{\text{int}} \right\rangle^{\Omega,C} \right]^2 \right\}, \quad (5.407)$$

$$\Delta E_0^{(2,2)} = 2 \frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\{ \left\langle \mathcal{A}_{\text{int}} \mathcal{A}_{\text{int,harm}} \right\rangle^{\Omega,C} - \left\langle \mathcal{A}_{\text{int}} \right\rangle^{\Omega,C} \left\langle \mathcal{A}_{\text{int,harm}} \right\rangle^{\Omega,C} \right\}, \quad (5.408)$$

and

$$\Delta E_0^{(2,3)} = -\frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\{ \langle \mathcal{A}_{\text{int,harm}}^2 \rangle^{\Omega,C} - [\langle \mathcal{A}_{\text{int,harm}} \rangle^{\Omega,C}]^2 \right\}. \quad (5.409)$$

The second term can be written as

$$\Delta E_0^{(2,2)} = -\frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\{ -2C \partial_C \langle \mathcal{A}_{\text{int}} \rangle^{\Omega,C} \right\}, \quad (5.410)$$

the third as

$$\Delta E_0^{(2,3)} = -\frac{1}{2\hbar\beta} \frac{1}{\hbar^2} \left\{ \{1 - C \partial_C\} \langle \mathcal{A}_{\text{int,harm}} \rangle^{\Omega,C} \right\}. \quad (5.411)$$

The final expression is rather involved and given in Appendix 5C. The second-order correction leads to the second term (5.398) found in perturbation theory. In the strong coupling limit, it changes the leading term $-\alpha^2/3\pi \approx -0.1061$ in (5.399) into

$$-\frac{1}{4\pi} - \frac{2}{\pi} \sum_{n=1}^{\infty} \frac{(2n)!}{2^{4n}(n!)^2 n(2n+1)} = \frac{-17 + 64 \arcsin(\frac{\sqrt{2-\sqrt{3}}}{2}) - 32 \log(4 \frac{\sqrt{2-\sqrt{3}}}{2})}{4\pi}, \quad (5.412)$$

which is approximately equal to -0.1078 . The corrections are shown numerically in the previous Table 5.12.

5.22.5 Polaron in Magnetic Field, Bipolarons, Small Polarons, Polaronic Excitons, and More

Feynman's solution of the polaron problem has instigated a great deal of research on this subject [34]. There are many publications dealing with a polaron in a magnetic field. In particular, there was considerable discussion on the validity of the Jensen-Peierls inequality (5.10) in the presence of a magnetic field until it was shown by Larsen in 1985 that the variational energy does indeed lie below the exact energy for sufficiently strong magnetic fields. On the basis of this result he criticized the entire approach. The problem was, however, solved by Devreese and collaborators who determined the range of variational parameters for which the inequality remained valid.

In the light of the systematic higher-order variational perturbation theory developed in this chapter we do not consider problems with the inequality any more as an obstacle to variational procedures. The optimization procedure introduced in Section 5.13 for even and odd approximations does not require an inequality. We have seen that for higher orders, the exact result will be approached rapidly with exponential convergence. The inequality is useful only in Feynman's original lowest-order variational approach where it is important to know the direction of the error. For higher orders, the importance of this information decreases rapidly since the convergence behavior allows us to estimate the limiting value quantitatively, whereas the inequality tells us merely the sign of the error which is often quite large in the lowest-order variational approach, for instance in the Coulomb system.

There is also considerable interest in bound states of two polarons called bipolarons. Such investigations have become popular since the discovery of high-temperature superconductivity.³

5.22.6 Variational Interpolation for Polaron Energy and Mass

Let us apply the method of variational interpolation developed in Section 5.18 to the polaron. Starting from the presently known weak-coupling expansions (5.397) and (5.404) we fix a few more expansion coefficients such that the curves fit also the strong-coupling expansions (5.400) and (5.405). We find it convenient to make the series start out with α^0 by removing an overall factor $-\alpha$ from E and deal with the quantity $-E_w^{\text{ex}}/\alpha$. Then we see from (5.400) that the correct leading power in the strong-coupling expansion requires taking $p = 1, q = 1$. The knowledge of b_0 and b_1 allows us to extend the known weak coupling expansion (5.397) by two further expansion terms. Their coefficients a_3, a_4 are solutions of the equations [recall (5.245)]

$$b_0 = \frac{35}{128}a_0c + a_1 + \frac{15}{8}\frac{a_2}{c} + \frac{2a_3}{c^2} + \frac{a_4}{c^3}, \quad (5.413)$$

$$b_1 = \frac{35}{32}\frac{a_0}{c} - \frac{5}{4}\frac{a_2}{c^3} - \frac{a_3}{c^3}. \quad (5.414)$$

The constant c governing the growth of Ω_N for $\alpha \rightarrow \infty$ is obtained by extremizing b_0 in c , which yields the equation

$$\frac{35}{128}a_0 - \frac{15}{8}\frac{a_2}{c^2} - \frac{4a_3}{c^3} - \frac{4a_4}{c^5} = 0. \quad (5.415)$$

The simultaneous solution of (5.413)–(5.415) renders

$$\begin{aligned} c_4 &= 0.09819868, \\ a_3 &= 6.43047343 \times 10^{-4}, \\ a_4 &= -8.4505836 \times 10^{-5}. \end{aligned} \quad (5.416)$$

The re-expanded energy (5.238) reads explicitly as a function of α and Ω (for E including the earlier-removed factor $-\alpha$)

$$\begin{aligned} W_4(\alpha, \Omega) &= a_0\alpha \left(-\frac{35}{128}\Omega - \frac{35}{32\Omega} + \frac{35}{64\Omega^3} - \frac{7}{32\Omega^5} + \frac{5}{128\Omega^7} \right) - a_1\alpha^2 \\ &+ a_2\alpha^3 \left(-\frac{15}{8\Omega} + \frac{5}{4\Omega^3} - \frac{3}{8\Omega^5} \right) + a_3\alpha^4 \left(-\frac{2}{\Omega^2} + \frac{1}{\Omega^4} \right) - a_4\alpha^5 \frac{1}{\Omega^3}. \end{aligned} \quad (5.417)$$

Extremizing this we find Ω_4 as a function of α [it turns out to be quite well approximated by the simple function $\Omega_4 \approx c_4\alpha + 1/(1 + 0.07\alpha)$]. This is to be compared with the optimal frequency obtained from minimizing the lower approximation $W_2(\alpha, \Omega)$:

$$\Omega_2^2 = 1 + \frac{4a_2}{3a_0}x^2 + \sqrt{\left(1 + \frac{4a_2}{3a_0}x^2\right)^2 - 1}, \quad (5.418)$$

which behaves like $c_2\alpha+1+\dots$ with $c_2 = \sqrt{8a_2/3a_0} \approx 0.120154$. The resulting energy is shown in Fig. 5.28, where it is compared with the Feynman variational energy. For completeness, we have also plotted the weak-coupling expansion, the strong-coupling expansion, the lower approximation $W_2(\alpha)$, and two Padé approximants given in Ref. [22] as upper and lower bounds to the energy.

Figure 5.28 Variational interpolation of polaron energy (solid line) between the weak-coupling expansion (dashed) and the strong-coupling expansion (short-dashed) shown in comparison with Feynman’s variational approximation (fat dots), which is an upper bound to the energy. The dotted curves are upper and lower bounds coming from Padé approximants [22]. The dot-dashed curve shows the variational perturbation theory $W_2(\alpha)$ which does not make use of the strong-coupling information.

Consider now the effective mass of the polaron, where the strong-coupling behavior (5.405) fixes $p = 4, q = 1$. The coefficient b_0 allows us to determine an approximate coefficient a_3 and to calculate the variational perturbation expansion $W_3(\alpha)$. From (5.245) we find the equation

$$b_0 = -a_1c^3/8 + a_3c, \tag{5.419}$$

whose minimum lies at $c_3 = \sqrt{8a_2/3a_0}$ where $b_0 = \sqrt{32a_3^3/27a_1}$. Equating b_0 of Eq. (5.419) with the leading coefficient in the strong-coupling expansion (5.405), we obtain $a_3 = [27a_1b_0^2/32]^{1/3} \approx 0.0416929$.

The variational expression for the polaron mass is from (5.238)

$$W_3(\alpha, \omega) = a_0 + a_1\alpha \left(-\frac{\Omega^3}{8} + \frac{3\Omega}{4} + \frac{3}{8\Omega} \right) + a_2\alpha^2 + a_3\alpha^3\Omega. \tag{5.420}$$

This is extremal at

$$\Omega_3^2 = 1 + \frac{4a_3}{3a_1}x^2 + \sqrt{\left(1 + \frac{4a_3}{3a_1}x^2\right)^2 - 1}. \tag{5.421}$$

Figure 5.29 Variational interpolation of polaron effective mass between the weak- (dashed) and strong-coupling expansions (short-dashed). To see better the differences between the strongly rising functions, we have divided out the asymptotic behavior $m_{\text{as}} = 1 + b_0\alpha^4$ before plotting the curves. The fat dots show Feynman's variational approximation. The dotted curves are upper and lower bounds coming from Padé approximants [22].

From this we may find once more $c_3 = \sqrt{8a_2/3a_0}$. The approximation $W_3(\alpha) = W_3(\alpha, \Omega_3)$ for the polaron mass is shown in Fig. 5.29, where it is compared with the weak and strong-coupling expansions and with Feynman's variational result. To see better the differences between the curves which all grow fast with α , we have divided out the asymptotic behavior $m_{\text{as}} = 1 + b_0\alpha^4$ before plotting the data. As for the energy, we have again displayed two Padé approximants given in Ref. [22] as upper and lower bounds to the energy. Note that our interpolation differs considerably from Feynman's and higher order expansion coefficients in the weak- or the strong-coupling expansions will be necessary to find out which is the true behavior of the model.

Our curve has, incidentally, the strong-coupling expansion

$$m^s = 0.0227019\alpha^4 + 0.125722\alpha^2 + 1.15304 + O(\alpha^{-2}), \quad (5.422)$$

the second term $\propto \alpha^2$ -term being in sharp contrast with Feynman's expression (5.403). On the weak-coupling side, a comparison of our expansion with Feynman's in Eq. (5.402) shows that our coefficient $a_3 \approx 0.0416929$ is about 10 times larger than his.

Both differences are the reason for our curve forming a positive arch in Fig. 2, whereas Feynman's has a valley. It will be interesting to find out how the polaron mass really behaves. This would be possible by calculating a few more terms in either the weak- or the strong-coupling expansion.

Note that our interpolation algorithm is much more powerful than Padé's. First, we can account for an arbitrary fractional leading power behavior α^p as $\alpha \rightarrow \infty$. Second, the successive lower powers in the strong-coupling expansion can be spaced by an arbitrary $2/q$. Third, our functions have in general a cut in the complex α -plane approximating the cuts in the function to be interpolated (see the discussion in Subsection 17.10.4). Padé approximants, in contrast, have always an integer power behavior in the strong-coupling limit, a unit spacing in the strong-coupling expansion, and poles to approximate cuts.

5.23 Density Matrices

In path integrals with fixed end points, the separate treatment of the path average $x_0 \equiv (1/\hbar\beta) \int_0^{\hbar\beta} d\tau x(\tau)$ loses its special virtues. Recall that the success of this separation in the variational approach was based on the fact that for fixed x_0 , the fluctuation square width $a^2(x_0)$ shrinks to zero for large temperatures like $\hbar^2/12Mk_B T$ [recall (5.25)]. A similar shrinking occurs for paths whose endpoints held fixed, which is the case in path integrals for the density. Thus there is no need for a separate treatment of x_0 , and one may develop a variational perturbation theory for fixed endpoints instead. These may, moreover, be taken to be different from one another $x_b \neq x_a$, thus allowing us to calculate directly density matrices.⁴

The density matrix is defined by the normalized expression

$$\rho(x_b, x_a) = \frac{1}{Z} \tilde{\rho}(x_b, x_a), \quad (5.423)$$

where $\tilde{\rho}(x_b, x_a)$ is the unnormalized transition amplitude given by the path integral

$$\tilde{\rho}(x_b, x_a) = (x_b \hbar\beta | x_a 0) = \int_{(x_a, 0) \sim (x_b, \hbar/k_B T)} \mathcal{D}x \exp \{ -\mathcal{A}[x]/\hbar \}, \quad (5.424)$$

summing all paths with the fixed endpoints $x(0) = x_a$ and $x(\hbar/k_B T) = x_b$. The diagonal matrix elements of the density matrix in the integrand yield, of course, the particle density (5.90). The diagonal elements coincide with the partition function density $z(x)$ introduced in Eq. (2.333).

The partition function divided out in (5.423) is found from the trace

$$Z = \int_{-\infty}^{\infty} dx \tilde{\rho}(x, x). \quad (5.425)$$

5.23.1 Harmonic Oscillator

As usual in the variational approach, we shall base the approximations to be developed on the exactly solvable density matrix of the harmonic oscillator. For the sake of generality, this will be assumed to be centered around x_m , with an action

$$\mathcal{A}_{\Omega, x_m}[x] = \int_0^{\hbar/k_B T} d\tau \left\{ \frac{1}{2} M \dot{x}^2(\tau) + \frac{1}{2} M \Omega^2 [x(\tau) - x_m]^2 \right\}. \quad (5.426)$$

⁴H. Kleinert, M. Bachmann, and A. Pelster, Phys. Rev. A 60, 3429 (1999) (quant-ph/9812063).

Its unnormalized density matrix is [see (2.411)]

$$\begin{aligned} \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) &= \sqrt{\frac{M\Omega}{2\pi\hbar \sinh \hbar\Omega/k_B T}} \\ &\times \exp \left\{ -\frac{M\Omega}{2\hbar \sinh \hbar\Omega/k_B T} \left[(\tilde{x}_b^2 + \tilde{x}_a^2) \cosh \hbar\Omega/k_B T - 2\tilde{x}_b\tilde{x}_a \right] \right\}, \end{aligned} \quad (5.427)$$

with the abbreviation

$$\tilde{x}(\tau) \equiv x(\tau) - x_m. \quad (5.428)$$

At fixed endpoints x_b, x_a and oscillation center x_m , the quantum-mechanical correlation functions are given by the path integral

$$\begin{aligned} \langle O_1(x(\tau_1)) O_2(x(\tau_2)) \cdots \rangle_{x_b, x_a}^{\Omega, x_m} &= \frac{1}{\tilde{\rho}_0^{\Omega, x_m}(x_b, x_a)} \\ &\times \int_{(x_a, 0) \sim (x_b, \hbar/k_B T)} \mathcal{D}x O_1(x(\tau_1)) O_2(x(\tau_2)) \cdots \exp \{ -\mathcal{A}_{\Omega, x_m}[x]/\hbar \}. \end{aligned} \quad (5.429)$$

The path $x(\tau)$ at a fixed imaginary time τ has a distribution

$$p(x, \tau) \equiv \langle \delta(x - x(\tau)) \rangle_{x_b, x_a}^{\Omega, x_m} = \frac{1}{\sqrt{2\pi b^2(\tau)}} \exp \left[-\frac{(\tilde{x} - x_{\text{cl}}(\tau))^2}{2b^2(\tau)} \right], \quad (5.430)$$

where $x_{\text{cl}}(\tau)$ is the classical path of a particle in the harmonic potential

$$x_{\text{cl}}(\tau) = \frac{\tilde{x}_b \sinh \Omega\tau + \tilde{x}_a \sinh \Omega(\hbar/k_B T - \tau)}{\sinh \hbar\Omega/k_B T}, \quad (5.431)$$

and $b^2(\tau)$ is the square width

$$b^2(\tau) = \frac{\hbar}{2M\Omega} \left\{ \coth \frac{\hbar\Omega}{k_B T} - \frac{\cosh[\Omega(2\tau - \hbar/k_B T)]}{\sinh \hbar\Omega/k_B T} \right\}. \quad (5.432)$$

In contrast to the square width $a^2(x_0)$ in Eq. (5.24) this depends on the Euclidean time τ , which makes calculations more cumbersome than before. Since the τ lies in the interval $0 \leq \tau \leq \hbar/k_B T$, the width (5.432) is bounded by

$$b^2(\tau) \leq \frac{\hbar}{2M\Omega} \tanh \frac{\hbar\Omega}{2k_B T}, \quad (5.433)$$

thus sharing with $a^2(x_0)$ the property of remaining finite at all temperatures. The temporal average of (5.432) is

$$\overline{b^2} = \frac{k_B T}{\hbar} \int_0^{\hbar/k_B T} d\tau b^2(\tau) = \frac{\hbar}{2M\Omega} \left(\coth \frac{\hbar\Omega}{k_B T} - \frac{k_B T}{\hbar\Omega} \right). \quad (5.434)$$

Just as $a^2(x_0)$, this goes to zero for $T \rightarrow \infty$. Note however, that the asymptotic behavior is

$$\overline{b^2} \xrightarrow{T \rightarrow \infty} \hbar\Omega/6k_B T, \quad (5.435)$$

which is twice as big as that of $a^2(x_0)$ in Eq. (5.25) (see Fig. 5.30).

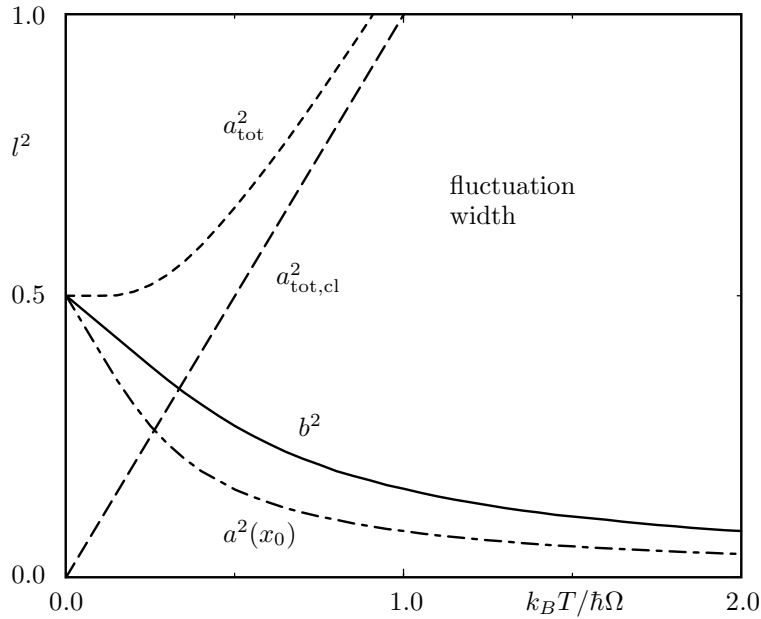

Figure 5.30 Temperature dependence of fluctuation widths of any point $x(\tau)$ on the path in a harmonic oscillator (l^2 is the generic square length in units of $\hbar/M\Omega$). The quantity a^2 (dashed) is the quantum-mechanical width, whereas $a^2(x_0)$ (dash-dotted) shares the width after separating out the fluctuations around the path average x_0 . The quantity a_{cl}^2 (long-dashed) is the width of the classical distribution, and b^2 (solid curve) is the fluctuation width at fixed ends which is relevant for the calculation of the density matrix by variational perturbation theory (compare Fig. 3.14).

5.23.2 Variational Perturbation Theory for Density Matrices

To obtain a variational approximation for the density matrix, we separate the full action into the harmonic trial action and a remainder

$$\mathcal{A}[x] = \mathcal{A}_{\Omega, x_m}[x] + \mathcal{A}_{\text{int}}[x], \quad (5.436)$$

with an interaction

$$\mathcal{A}_{\text{int}}[x(\tau)] = \int_0^{\hbar\beta} d\tau V_{\text{int}}(x(\tau)), \quad (5.437)$$

where the interaction potential is the difference between the original one $V(x)$ and the inserted displaced harmonic oscillator:

$$V_{\text{int}}(x(\tau)) = V(x(\tau)) - \frac{1}{2}M\Omega^2[x(\tau) - x_m]^2. \quad (5.438)$$

The path integral (5.424) is then expanded perturbatively around the harmonic expression (5.427) as

$$\tilde{\rho}(x_b, x_a) = \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) \left[1 - \frac{1}{\hbar} \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_b, x_a}^{\Omega, x_m} + \frac{1}{2\hbar^2} \langle \mathcal{A}_{\text{int}}^2[x] \rangle_{x_b, x_a}^{\Omega, x_m} - \dots \right], \quad (5.439)$$

with the harmonic expectation values defined in (5.429). The sum can be evaluated as an exponential of its connected parts, going over to the cumulant expansion:

$$\tilde{\rho}(x_b, x_a) = \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) \exp \left[-\frac{1}{\hbar} \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_b, x_a, c}^{\Omega, x_m} + \frac{1}{2\hbar^2} \langle \mathcal{A}_{\text{int}}^2[x] \rangle_{x_b, x_a, c}^{\Omega, x_m} - \dots \right], \quad (5.440)$$

where the cumulants are defined as usual [see (3.485), (3.486)]. The series (5.440) is truncated after the N -th term, resulting in the N -th order approximant for the quantum statistical density matrix

$$\tilde{\rho}_N^{\Omega, x_m}(x_b, x_a) = \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) \exp \left[\sum_{n=1}^N \frac{(-1)^n}{n! \hbar^n} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_b, x_a, c}^{\Omega, x_m} \right], \quad (5.441)$$

which explicitly depends on the two variational parameters Ω and x_m .

By analogy with classical statistics, where the Boltzmann distribution in configuration space is controlled by the classical potential $V(x)$ according to [recall (2.354)]

$$\tilde{\rho}_{\text{cl}}(x) = \sqrt{\frac{M}{2\pi\hbar^2\beta}} \exp[-\beta V(x)], \quad (5.442)$$

we shall now work with the alternative type of *effective classical potential* $\tilde{V}^{\text{eff,cl}}(x_a, x_b)$ introduced in Subsection 3.25.4. It governs the unnormalized density matrix [see Eq. (3.837)]

$$\tilde{\rho}(x_b, x_a) = \sqrt{\frac{M}{2\pi\hbar^2\beta}} \exp[-\beta \tilde{V}^{\text{eff,cl}}(x_b, x_a)]. \quad (5.443)$$

Variational approximations to $\tilde{V}^{\text{eff,cl}}(x_b, x_a)$ of N th order are obtained from (5.427), (5.441), and (5.443) as a cumulant expansion

$$\begin{aligned} \tilde{W}_N^{\Omega, x_m}(x_b, x_a) &= \frac{1}{2\beta} \ln \frac{\sinh \hbar\beta\Omega}{\hbar\beta\Omega} + \frac{M\Omega}{2\hbar\beta \sinh \hbar\beta\Omega} \left\{ (\tilde{x}_b^2 + \tilde{x}_a^2) \cosh \hbar\beta\Omega - 2\tilde{x}_b\tilde{x}_a \right\} \\ &- \frac{1}{\beta} \sum_{n=1}^N \frac{(-1)^n}{n! \hbar^n} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_b, x_a, c}^{\Omega, x_m}. \end{aligned} \quad (5.444)$$

They have to be optimized in the variational parameters Ω and x_m for a pair of endpoints x_b, x_a . The result is denoted by $\tilde{W}_N(x_b, x_a)$. The optimal values $\Omega(x_a, x_b)$ and $x_m(x_a, x_b)$ are denoted by $\Omega_N(x_a, x_b), x_m^N(x_a, x_b)$. The N th-order approximation for the normalized density matrix is then given by

$$\rho_N(x_b, x_a) = Z_N^{-1} \tilde{\rho}_N^{\Omega_N, x_m^N}(x_b, x_a), \quad (5.445)$$

where the corresponding partition function reads

$$Z_N = \int_{-\infty}^{\infty} dx_a \tilde{\rho}_N^{\Omega_N, x_m^N}(x_a, x_a). \quad (5.446)$$

In principle, one could also optimize the entire ratio (5.445), but this would be harder to do in practice. Moreover, the optimization of the unnormalized density matrix is the only option, if the normalization diverges due to singularities of the potential, for example in the hydrogen atom

5.23.3 Smearing Formula for Density Matrices

In order to calculate the connected correlation functions in the variational perturbation expansion (5.441), we must find efficient formulas for evaluating expectation values (5.429) of any power of the interaction (5.437)

$$\begin{aligned} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_b, x_a}^{\Omega, x_m} &= \frac{1}{\tilde{\rho}_0^{\Omega, x_m}(x_b, x_a)} \int_{\tilde{x}_{a,0}}^{\tilde{x}_b, \hbar\beta} \mathcal{D}\tilde{x} \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l V_{\text{int}}(\tilde{x}(\tau_l) + x_m) \right] \\ &\times \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_{\Omega, x_m}[\tilde{x} + x_m] \right\}. \end{aligned} \quad (5.447)$$

This can be done by an extension of the smearing formula (5.30). For this we rewrite the interaction potential as

$$V_{\text{int}}(\tilde{x}(\tau_l) + x_m) = \int_{-\infty}^{\infty} dz_l V_{\text{int}}(z_l + x_m) \int_{-\infty}^{\infty} \frac{d\lambda_l}{2\pi} e^{i\lambda_l z_l} \exp \left[-\int_0^{\hbar\beta} d\tau i\lambda_l \delta(\tau - \tau_l) \tilde{x}(\tau) \right], \quad (5.448)$$

and introduce a current

$$J(\tau) = \sum_{l=1}^n i\hbar \lambda_l \delta(\tau - \tau_l), \quad (5.449)$$

so that (5.447) becomes

$$\langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_b, x_a}^{\Omega, x_m} = \frac{1}{\tilde{\rho}_0^{\Omega, x_m}(x_b, x_a)} \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l \int_{-\infty}^{\infty} dz_l V_{\text{int}}(z_l + x_{\text{min}}) \int_{-\infty}^{\infty} \frac{d\lambda_l}{2\pi} e^{i\lambda_l z_l} \right] K^{\Omega, x_m}[j]. \quad (5.450)$$

The kernel $K^{\Omega, x_m}[j]$ represents the generating functional for all correlation functions of the displaced harmonic oscillator

$$K^{\Omega, x_m}[j] = \int_{\tilde{x}_{a,0}}^{\tilde{x}_b, \hbar\beta} \mathcal{D}\tilde{x} \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \left[\frac{m}{2} \dot{\tilde{x}}^2(\tau) + \frac{1}{2} M\Omega^2 \tilde{x}^2(\tau) + j(\tau) \tilde{x}(\tau) \right] \right\}. \quad (5.451)$$

For zero current j , this generating functional reduces to the Euclidean harmonic propagator (5.427):

$$K^{\Omega, x_m}[j = 0] = \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a), \quad (5.452)$$

and the solution of the functional integral (5.451) is given by (recall Section 3.1)

$$\begin{aligned} K^{\Omega, x_m}[j] &= \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) \exp \left[-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau j(\tau) x_{\text{cl}}(\tau) \right. \\ &\quad \left. + \frac{1}{2\hbar^2} \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' j(\tau) G_{\Omega^2}^{(2)}(\tau, \tau') j(\tau') \right], \end{aligned} \quad (5.453)$$

where $x_{\text{cl}}(\tau)$ denotes the classical path (5.431) and $G_{\Omega^2}^{(2)}(\tau, \tau')$ the harmonic Green function with Dirichlet boundary conditions (3.389), to be written here as

$$G_{\Omega^2}^{(2)}(\tau, \tau') = \frac{\hbar}{2M\Omega} \frac{\cosh \Omega(|\tau - \tau'| - \hbar\beta) - \cosh \Omega(\tau + \tau' - \hbar\beta)}{\sinh \hbar\beta\Omega}. \quad (5.454)$$

The expression (5.453) can be simplified by using the explicit expression (5.449) for the current j . This leads to a generating functional

$$K^{\Omega, x_m}[j] = \tilde{\rho}_0^{\Omega, x_m}(x_b, x_a) \exp\left(-i\boldsymbol{\lambda}^T \mathbf{x}_{\text{cl}} - \frac{1}{2} \boldsymbol{\lambda}^T G \boldsymbol{\lambda}\right), \quad (5.455)$$

where we have introduced the n -dimensional vectors $\boldsymbol{\lambda} = (\lambda_1, \dots, \lambda_n)$ and $\mathbf{x}_{\text{cl}} = (x_{\text{cl}}(\tau_1), \dots, x_{\text{cl}}(\tau_n))^T$ with the superscript T denoting transposition, and the symmetric $n \times n$ -matrix G whose elements are $G_{kl} = G_{\Omega^2}^{(2)}(\tau_k, \tau_l)$. Inserting (5.455) into (5.450), and performing the integrals with respect to $\lambda_1, \dots, \lambda_n$, we obtain the n -th order smearing formula for the density matrix

$$\begin{aligned} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_b, x_a}^{\Omega, x_m} &= \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l \int_{-\infty}^{\infty} dz_l V_{\text{int}}(z_l + x_m) \right] \\ &\times \frac{1}{\sqrt{(2\pi)^n \det G}} \exp \left\{ -\frac{1}{2} \sum_{k,l=1}^n [z_k - x_{\text{cl}}(\tau_k)] G_{kl}^{-1} [z_l - x_{\text{cl}}(\tau_l)] \right\}. \end{aligned} \quad (5.456)$$

The integrand contains an n -dimensional Gaussian distribution describing both thermal and quantum fluctuations around the harmonic classical path $x_{\text{cl}}(\tau)$ of Eq. (5.431) in a trial oscillator centered at x_m , whose width is governed by the Green functions (5.454).

For closed paths with coinciding endpoints ($x_b = x_a$), formula (5.456) leads to the n -th order smearing formula for particle densities

$$\rho(x_a) = \frac{1}{Z} \tilde{\rho}(x_a, x_a) = \frac{1}{Z} \oint \mathcal{D}x \delta(x(\tau = 0) - x_a) \exp\{-\mathcal{A}[x]/\hbar\}, \quad (5.457)$$

which can be written as

$$\begin{aligned} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_a, x_a}^{\Omega, x_m} &= \frac{1}{\rho_0^{\Omega, x_m}(x_a)} \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l \int_{-\infty}^{\infty} dz_l V_{\text{int}}(z_l + x_m) \right] \\ &\times \frac{1}{\sqrt{(2\pi)^{n+1} \det a^2}} \exp \left(-\frac{1}{2} \sum_{k,l=0}^n z_k a_{kl}^{-2} z_l \right), \end{aligned} \quad (5.458)$$

with $z_0 = \tilde{x}_a$. Here a denotes a symmetric $(n+1) \times (n+1)$ -matrix whose elements $a_{kl}^2 = a^2(\tau_k, \tau_l)$ are obtained from the harmonic Green function for periodic paths $G_{\Omega^2}^{(2)}(\tau, \tau')$ of Eq. (3.304):

$$a^2(\tau, \tau') \equiv \frac{\hbar}{M} G_{\Omega^2}^{(2)}(\tau, \tau') = \frac{\hbar}{2M\Omega} \frac{\cosh \Omega(|\tau - \tau'| - \hbar\beta/2)}{\sinh \hbar\beta\Omega/2}. \quad (5.459)$$

The diagonal elements $a^2 = a(\tau, \tau)$ are all equal to the fluctuation square width (5.24).

Both smearing formulas (5.456) and (5.458) allow us to calculate all harmonic expectation values for the variational perturbation theory of density matrices and particle densities in terms of ordinary Gaussian integrals. Unfortunately, in many applications containing nonpolynomial potentials, it is impossible to solve neither the spatial nor the temporal integrals analytically. This circumstance drastically increases the numerical effort in higher-order calculations.

5.23.4 First-Order Variational Approximation

The first-order variational approximation gives usually a reasonable estimate for any desired quantity. Let us investigate the classical and the quantum-mechanical limit of this approximation. To facilitate the discussion, we first derive a new representation for the first-order smearing formula (5.458) which allows a direct evaluation of the imaginary time integral. The resulting expression will depend only on temperature, whose low- and high-temperature limits can easily be extracted.

Alternative First-Order Smearing Formula

For simplicity, we restrict ourselves to the case of particle densities and allow only symmetric potentials $V(x)$ centered at the origin. If $V(x)$ has only one minimum at the origin, then also x_m will be zero. If $V(x)$ has several symmetric minima, then x_m goes to zero only at sufficiently high temperatures as in Section 5.7.

To first order, the smearing formula (5.458) reads

$$\langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^{\Omega} = \frac{1}{\rho_0^{\Omega}(x_a)} \int_0^{\hbar\beta} d\tau \int_{-\infty}^{\infty} \frac{dz}{2\pi} V_{\text{int}}(z) \frac{1}{\sqrt{a_{00}^2 - a_{01}^2}} \exp \left\{ -\frac{1}{2} \frac{(z^2 + x_a^2)a_{00} - 2zx_a a_{01}}{a_{00}^2 - a_{01}^2} \right\}. \quad (5.460)$$

Expanding the exponential with the help of Mehler's formula (2.297), we obtain the following expansion in terms of Hermite polynomials $H_n(x)$:

$$\langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^{\Omega} = \sum_{n=0}^{\infty} \frac{\hbar\beta}{2^n n!} C_{\beta}^{(n)} H_n \left(\frac{z}{\sqrt{2a_{00}^2}} \right) \int_{-\infty}^{\infty} \frac{dz}{\sqrt{2\pi a_{00}^2}} V_{\text{int}}(z) e^{-z^2/2a_{00}^2} H_n \left(\frac{z}{\sqrt{2a_{00}^2}} \right). \quad (5.461)$$

Its temperature dependence stems from the diagonal elements of the harmonic Green function (5.459). The dimensionless functions $C_{\beta}^{(n)}$ are defined by

$$C_{\beta}^{(n)} = \frac{1}{\hbar\beta} \int_0^{\hbar\beta} d\tau \left(\frac{a_{01}^2}{a_{00}^2} \right)^n. \quad (5.462)$$

Figure 5.31 Temperature-dependence of first 9 functions $C_\beta^{(n)}$, where $\beta = 1/k_B T$.

Inserting (5.459) and performing the integral over τ , we obtain

$$C_\beta^{(n)} = \frac{1}{2^n \cosh^n \hbar\beta\Omega/2} \sum_{k=0}^n \binom{n}{k} \frac{\sinh \hbar\beta\Omega(n/2 - k)}{\hbar\beta\Omega(n/2 - k)}. \quad (5.463)$$

At high temperatures, these functions of β go to unity:

$$\lim_{\beta \rightarrow 0} C_\beta^{(n)} = 1. \quad (5.464)$$

Their zero-temperature limits are

$$\lim_{\beta \rightarrow \infty} C_\beta^{(n)} = \begin{cases} 1, & n = 0, \\ \frac{2}{\hbar\beta\Omega n}, & n > 0. \end{cases} \quad (5.465)$$

According to (5.444), the first-order approximation to the new effective potential is given by

$$\tilde{W}_1^\Omega(x_a) = \frac{1}{2\beta} \ln \frac{\sinh \hbar\beta\Omega}{\hbar\beta\Omega} + \frac{M\Omega}{\hbar\beta} x_a^2 \tanh \frac{\hbar\beta\Omega}{2} + V_{a^2}^\Omega(x_a), \quad (5.466)$$

with the smeared interaction potential

$$V_{a^2}^\Omega(x_a) = \frac{1}{\hbar\beta} \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega. \quad (5.467)$$

It is instructive to discuss separately the limits $\beta \rightarrow 0$ and $\beta \rightarrow \infty$ to see the effects of pure classical and pure quantum fluctuations.

a) Classical Limit of Effective Classical Potential

In the classical limit $\beta \rightarrow 0$, the first-order effective classical potential (5.466) reduces to

$$\tilde{W}_1^{\Omega, \text{cl}}(x_a) = \frac{1}{2} M \Omega^2 x_a^2 + \lim_{\beta \rightarrow 0} V_{a^2}^{\Omega}(x_a). \quad (5.468)$$

The second term is determined by inserting the high-temperature limit of the total fluctuation width (5.26):

$$a_{\text{tot,cl}}^2 = \frac{k_B T}{M \Omega^2}, \quad (5.469)$$

and of the polynomials (5.464) into the expansion (5.461), leading to

$$V_{a^2}^{\Omega}(x_a)_{T \rightarrow \infty} \approx \sum_{n=0}^{\infty} \frac{1}{2^n n!} H_n \left(\sqrt{\frac{M \Omega^2 \beta}{2}} x_a \right) \int_{-\infty}^{\infty} \frac{dz}{\sqrt{2\pi/M \Omega^2 \beta}} V_{\text{int}}(z) e^{-M \Omega^2 \beta z^2 / 2} H_n \left(\frac{M \Omega^2 \beta}{2} z \right). \quad (5.470)$$

Then we make use of the completeness relation for Hermite polynomials

$$\frac{1}{\sqrt{\pi}} e^{-x^2} \sum_{n=0}^{\infty} \frac{1}{2^n n!} H_n(x) H_n(x') = \delta(x - x'), \quad (5.471)$$

which may be derived from Mehler's formula (2.297) in the limit $b \rightarrow 1^-$, to reduce the smeared interaction potential $V_{a^2}^{\Omega}(x_a)$ to the pure interaction potential (5.438):

$$\lim_{\beta \rightarrow 0} V_{a^2}^{\Omega}(x_a) = V_{\text{int}}(x_a). \quad (5.472)$$

Recalling (5.438) we see that the first-order effective classical potential (5.468) approaches the classical one:

$$\lim_{\beta \rightarrow 0} \tilde{W}_1^{\Omega, \text{cl}}(x_a) = V(x_a). \quad (5.473)$$

This is a consequence of the vanishing fluctuation width b^2 of the paths around the classical orbits. This property is universal to all higher-order approximations to the effective classical potential (5.444). Thus all correction terms with $n > 1$ must disappear in the limit $\beta \rightarrow 0$,

$$\lim_{\beta \rightarrow 0} \frac{-1}{\beta} \sum_{n=2}^{\infty} \frac{(-1)^n}{n! \hbar^n} \langle \mathcal{A}_{\text{int}}^n[x] \rangle_{x_a, x_a, c}^{\Omega} = 0. \quad (5.474)$$

b) Zero-Temperature Limit

At low temperatures, the first-order effective classical potential (5.466) becomes

$$\tilde{W}_1^{\Omega, \text{qm}}(x_a) = \frac{\hbar \Omega}{2} + \lim_{\beta \rightarrow \infty} V_{a^2}^{\Omega}(x_a). \quad (5.475)$$

The zero-temperature limit of the smeared potential in the second term defined in (5.467) follows from Eq. (5.461) by taking into account the limiting procedure for the polynomials $C_\beta^{(n)}$ in (5.465) and the zero-temperature limit of the total fluctuation width (5.26), which is equal to the zero-temperature limit of $a^2(x_0)$: $a_{\text{tot},0}^2 \stackrel{T=0}{=} a_{\text{tot}}^2 = \hbar/2M\Omega$. Thus we obtain with $H_0(x) = 1$ and the inverse length $\kappa \equiv 1/\lambda_\Omega = \sqrt{M\Omega/\hbar}$ [recall (2.303)]:

$$\lim_{\beta \rightarrow \infty} V_{a^2}^\Omega(x_a) = \int_{-\infty}^{\infty} dz \sqrt{\frac{\kappa^2}{\pi}} H_0(\kappa z)^2 \exp\{-\kappa^2 z^2\} V_{\text{int}}(z). \quad (5.476)$$

Introducing the harmonic eigenvalues

$$E_n^\Omega = \hbar\Omega \left(n + \frac{1}{2} \right), \quad (5.477)$$

and the harmonic eigenfunctions [recall (2.301) and (2.302)]

$$\psi_n^\Omega(x) = \frac{1}{\sqrt{n!2^n}} \left(\frac{\kappa^2}{\pi} \right)^{1/4} e^{-\frac{1}{2}\kappa^2 x^2} H_n(\kappa x), \quad (5.478)$$

we can re-express the zero-temperature limit of the first-order effective classical potential (5.475) with (5.476) by

$$\tilde{W}_1^{\Omega, \text{qm}}(x_a) = E_0^\Omega + \langle \psi_0^\Omega | V_{\text{int}} | \psi_0^\Omega \rangle. \quad (5.479)$$

This is recognized as the first-order Rayleigh-Schrödinger perturbative result for the ground state energy.

For the discussion of the quantum-mechanical limit of the first-order normalized density,

$$\rho_1^\Omega(x_a) = \frac{\tilde{\rho}_1^\Omega(x_a)}{Z} = \rho_0^\Omega(x_a) \frac{\exp\left\{-\frac{1}{\hbar} \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega\right\}}{\int_{-\infty}^{\infty} dx_a \rho_0^\Omega(x_a) \exp\left\{-\frac{1}{\hbar} \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega\right\}}, \quad (5.480)$$

we proceed as follows. First we expand (5.480) up to first order in the interaction, leading to

$$\rho_1^\Omega(x_a) = \rho_0^\Omega(x_a) \left[1 - \frac{1}{\hbar} \left(\langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega - \int_{-\infty}^{\infty} dx_a \rho_0^\Omega(x_a) \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega \right) \right]. \quad (5.481)$$

Inserting (5.428) and (5.461) into the third term in (5.481), and assuming Ω not to depend explicitly on x_a , the x_a -integral reduces to the orthonormality relation for Hermite polynomials

$$\frac{1}{2^n n! \sqrt{\pi}} \int_{-\infty}^{\infty} dx_a H_n(x_a) H_0(x_a) e^{-x_a^2} = \delta_{n0}, \quad (5.482)$$

so that the third term in (5.481) eventually becomes

$$-\int_{-\infty}^{\infty} dx_a \rho_0^\Omega(x_a) \langle \mathcal{A}_{\text{int}}[x] \rangle_{x_a, x_a}^\Omega = -\beta \int_{-\infty}^{\infty} dz \sqrt{\frac{\kappa^2}{\pi}} V_{\text{int}}(z) \exp\{-\kappa^2 z^2\} H_0(\kappa z). \quad (5.483)$$

But this is just the $n = 0$ -term of (5.461) with an opposite sign, thus canceling the zeroth component of the second term in (5.481), which would have been divergent for $\beta \rightarrow \infty$.

The resulting expression for the first-order normalized density is

$$\rho_1^\Omega(x_a) = \rho_0^\Omega(x_a) \left[1 - \sum_{n=1}^{\infty} \frac{\beta}{2^n n!} C_\beta^{(n)} H_n(\kappa x_a) \int_{-\infty}^{\infty} dz \sqrt{\frac{\kappa^2}{\pi}} V_{\text{int}}(z) \exp(-\kappa^2 z^2) H_n(\kappa z) \right]. \quad (5.484)$$

The zero-temperature limit of $C_\beta^{(n)}$ is from (5.465) and (5.477)

$$\lim_{\beta \rightarrow \infty} \beta C_\beta^{(n)} = \frac{2}{E_n^\Omega - E_0^\Omega}, \quad (5.485)$$

so that we obtain from (5.484) the limit

$$\begin{aligned} \rho_1^\Omega(x_a) &= \rho_0^\Omega(x_a) \left[1 - 2 \sum_{n=1}^{\infty} \frac{1}{2^n n!} \frac{1}{E_n^\Omega - E_0^\Omega} H_n(\kappa x_a) \right. \\ &\quad \times \left. \int_{-\infty}^{\infty} dz \sqrt{\frac{\kappa^2}{\pi}} V_{\text{int}}(z) \exp\{-\kappa^2 z^2\} H_n(\kappa z) H_0(\kappa z) \right]. \end{aligned} \quad (5.486)$$

Taking into account the harmonic eigenfunctions (5.478), we can rewrite (5.486) as

$$\rho_1^\Omega(x_a) = |\psi_0(x_a)|^2 = [\psi_0^\Omega(x_a)]^2 - 2\psi_0^\Omega(x_a) \sum_{n>0} \psi_n^\Omega(x_a) \frac{\langle \psi_n^\Omega | V_{\text{int}} | \psi_0^\Omega \rangle}{E_n^\Omega - E_0^\Omega}, \quad (5.487)$$

which is just equivalent to the harmonic first-order Rayleigh-Schrödinger result for particle densities.

Summarizing the results of this section, we have shown that our method has properly reproduced the high- and low-temperature limits. Due to relation (5.487), the variational approach for particle densities can be used to determine approximately the ground state wave function $\psi_0(x_a)$ for the system of interest.

5.23.5 Smearing Formula in Higher Spatial Dimensions

Most physical systems possess many degrees of freedom. This requires an extension of our method to higher spatial dimensions. In general, we must consider anisotropic harmonic trial systems, where the previous variational parameter Ω^2 becomes a $D \times D$ -matrix $\Omega_{\mu\nu}^2$ with $\mu, \nu = 1, 2, \dots, D$.

a) Isotropic Approximation

An isotropic trial ansatz

$$\Omega_{\mu\nu}^2 = \Omega^2 \delta_{\mu\nu} \tag{5.488}$$

can give rough initial estimates for the properties of the system. In this case, the n -th order smearing formula (5.458) generalizes directly to

$$\begin{aligned} \langle \mathcal{A}_{\text{int}}^n[\mathbf{r}] \rangle_{\mathbf{r}_a, \mathbf{r}_a}^\Omega &= \frac{1}{\rho_0^\Omega(\mathbf{r}_a)} \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l \int d^D z_l V_{\text{int}}(\mathbf{z}_l) \right] \\ &\times \frac{1}{\sqrt{(2\pi)^{n+1} \det a^2{}^D}} \exp \left[-\frac{1}{2} \sum_{k,l=0}^n \mathbf{z}_k a_{kl}^{-2} \mathbf{z}_l \right], \end{aligned} \tag{5.489}$$

with the D -dimensional vectors $\mathbf{z}_l = (z_{1l}, z_{2l}, \dots, z_{Dl})^T$. Note, that Greek labels $\mu, \nu, \dots = 1, 2, \dots, D$ specify spatial indices and Latin labels $k, l, \dots = 0, 1, 2, \dots, n$ refer to the different imaginary times. The vector \mathbf{z}_0 denotes \mathbf{r}_a , the matrix a^2 is the same as in Subsection 5.23.3. The harmonic density reads

$$\rho_0^\Omega(\mathbf{r}) = \sqrt{\frac{1}{2\pi a_{00}^2}{}^D} \exp \left[-\frac{1}{2} \sum_{\mu=1}^D x_\mu^2 \right]. \tag{5.490}$$

b) Anisotropic Approximation

In the discussion of the anisotropic approximation, we shall only consider radially-symmetric potentials $V(\mathbf{r}) = V(|\mathbf{r}|)$ because of their simplicity and their major occurrence in physics. The trial frequencies decompose naturally into a radial frequency Ω_L and a transverse one Ω_T as in (5.95):

$$\Omega_{\mu\nu}^2 = \Omega_L^2 \frac{x_{a\mu} x_{a\nu}}{r_a^2} + \Omega_T^2 \left(\delta_{\mu\nu} - \frac{x_{a\mu} x_{a\nu}}{r_a^2} \right), \tag{5.491}$$

with $r_a = |\mathbf{r}_a|$. For practical reasons we rotate the coordinate system by $\bar{\mathbf{x}}_n = U \mathbf{x}_n$ so that $\bar{\mathbf{r}}_a$ points along the first coordinate axis,

$$(\bar{\mathbf{r}}_a)_\mu \equiv \bar{z}_{\mu 0} = \begin{cases} r_a, & \mu = 1, \\ 0, & 2 \leq \mu \leq D, \end{cases} \tag{5.492}$$

and Ω^2 -matrix is diagonal:

$$\bar{\Omega}^2 = \begin{pmatrix} \Omega_L^2 & 0 & 0 & \cdots & 0 \\ 0 & \Omega_T^2 & 0 & \cdots & 0 \\ 0 & 0 & \Omega_T^2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & \Omega_T^2 \end{pmatrix} = U \Omega^2 U^{-1}. \tag{5.493}$$

After this rotation, the *anisotropic* n -th order smearing formula in D dimensions reads

$$\begin{aligned} \langle \mathcal{A}_{\text{int}}^n[\mathbf{r}] \rangle_{\mathbf{r}_a, \mathbf{r}_a}^{\Omega_L, \Omega_T} &= \frac{1}{\rho_0^{\Omega_L, \Omega_T}(\bar{\mathbf{r}}_a)} \prod_{l=1}^n \left[\int_0^{\hbar\beta} d\tau_l \int d^D \bar{z}_l V_{\text{int}}(|\bar{\mathbf{z}}_l|) \right] (2\pi)^{-D(n+1)/2} \\ &\times (\det a_L^2)^{-1/2} (\det a_T^2)^{-(D-1)/2} e^{-\frac{1}{2} \sum_{k,l=0}^n \bar{z}_{1k} a_{Lkl}^{-2} \bar{z}_{1l}} e^{-\frac{1}{2} \sum_{\mu=2}^D \sum_{k,l=1}^n \bar{z}_{\mu k} a_{Tkl}^{-2} \bar{z}_{\mu l}}. \end{aligned} \tag{5.494}$$

The components of the longitudinal and transversal matrices a_L^2 and a_T^2 are

$$a_{Lkl}^2 = a_L^2(\tau_k, \tau_l), \quad a_{Tkl}^2 = a_T^2(\tau_k, \tau_l), \quad (5.495)$$

where the frequency Ω in (5.459) must be substituted by the new variational parameters Ω_L, Ω_T , respectively. For the harmonic density in the rotated system $\rho_0^{\Omega_L, T}(\bar{\mathbf{r}})$ which is used to normalize (5.494), we find

$$\rho_0^{\Omega_L, T}(\bar{\mathbf{r}}) = \sqrt{\frac{1}{2\pi a_{L00}^2}} \sqrt{\frac{1}{2\pi a_{T00}^2}}^{D-1} \exp \left[-\frac{1}{2 a_{L00}^2} \bar{x}_1^2 - \frac{1}{2 a_{T00}^2} \sum_{\mu=2}^D \bar{x}_\mu^2 \right]. \quad (5.496)$$

Appendix 5A Feynman Integrals for $T \neq 0$ without Zero Frequency

The Feynman integrals needed in variational perturbation theory of the anharmonic oscillator at nonzero temperature can be calculated in close analogy to those of ordinary perturbation theory in Section 3.20. The calculation proceeds as explained in Appendix 3D, except that the lines represent now the thermal correlation function (5.19) with the zero-frequency subtracted from the spectral decomposition:

$$G_{\tilde{\Omega}}^{(2)x_0}(\tau, \tau') = \frac{1}{2\tilde{\Omega}} \left[\frac{\cosh \tilde{\Omega}(|\tau - \tau'| - \hbar\beta/2)}{\sinh(\tilde{\Omega}\hbar\beta/2)} \right] - \frac{1}{\hbar\beta\tilde{\Omega}^2}.$$

With the dimensionless variable $x \equiv \hbar\beta\tilde{\omega}$, the results for the quantities a_V^{2L} defined of each Feynman diagram with L lines and V vertices as in (3.550), but now without the zero Matsubara frequency, are [compare with the results (3D.3)–(3D.11)]

$$a^2 = \frac{\hbar}{\tilde{\omega}} \frac{1}{x} \left(\frac{x}{2} \coth \frac{x}{2} - 1 \right), \quad (5A.1)$$

$$a_2^4 = \left(\frac{\hbar}{\tilde{\omega}} \right)^2 \frac{1}{8x} \frac{1}{\sinh^2 \frac{x}{2}} (4 + x^2 - 4 \cosh x + x \sinh x), \quad (5A.2)$$

$$a_3^6 = \left(\frac{\hbar}{\tilde{\omega}} \right)^3 \frac{1}{64x} \frac{1}{\sinh^3 \frac{x}{2}} \left(-3x \cosh \frac{x}{2} + 2x^3 \cosh \frac{x}{2} + 3x \cosh \frac{3x}{2} + 48 \sinh \frac{x}{2} + 6x^2 \sinh \frac{x}{2} - 16 \sinh \frac{3x}{2} \right), \quad (5A.3)$$

$$a_2^8 = \left(\frac{\hbar}{\tilde{\omega}} \right)^4 \frac{1}{768x^3} \frac{1}{\sinh^4 \frac{x}{2}} (-864 + 18x^4 + 1152 \cosh x + 32x^2 \cosh x - 288 \cosh 2x - 32x^2 \cosh 2x - 288x \sinh x + 24x^3 \sinh x + 144x \sinh 2x + 3x^3 \sinh 2x), \quad (5A.4)$$

$$a_3^{10} = \left(\frac{\hbar}{\tilde{\omega}} \right)^5 \frac{1}{4096x^3} \frac{1}{\sinh^5 \frac{x}{2}} \left(672x \cosh \frac{x}{2} - 8x^3 \cosh \frac{x}{2} + 24x^5 \cosh \frac{x}{2} - 1008x \cosh \frac{3x}{2} + 3x^3 \cosh \frac{3x}{2} + 336x \cosh \frac{5x}{2} + 5x^3 \cosh \frac{5x}{2} - 7680 \sinh \frac{x}{2} - 352x^2 \sinh \frac{x}{2} + 72x^4 \sinh \frac{x}{2} + 3840 \sinh \frac{3x}{2} + 224x^2 \sinh \frac{3x}{2} + 12x^4 \sinh \frac{3x}{2} - 768 \sinh \frac{5x}{2} - 64x^2 \sinh \frac{5x}{2} \right), \quad (5A.5)$$

$$\begin{aligned}
 a_3^{12} = & \left(\frac{\hbar}{\tilde{\omega}}\right)^6 \frac{1}{49152x^4} \frac{1}{\sinh^6 \frac{x}{2}} \left(-107520 - 7360 x^2 + 624 x^4 + 96 x^6 \right. \\
 & +161280 \cosh x + 12000 x^2 \cosh x - 777 x^4 \cosh x + 24 x^6 \cosh x \\
 & -64512 \cosh 2x - 5952 x^2 \cosh 2x + 144 x^4 \cosh 2x + 10752 \cosh 3x \\
 & -28800 x \sinh x + 1312 x^2 \cosh 3x + 9 x^4 \cosh 3x + 1120 x^3 \sinh x \\
 & +324 x^5 \sinh x + 23040 x \sinh 2x - 320 x^3 \sinh 2x - 5760 x \sinh 3x \\
 & \left. -160 x^3 \sinh 3x\right), \tag{5A.6}
 \end{aligned}$$

$$\begin{aligned}
 a_2^6 = & \left(\frac{\hbar}{\tilde{\omega}}\right)^3 \frac{1}{24x^2} \frac{1}{\sinh^2 \frac{x}{2}} \left(-24 - 4x^2 + 24 \cosh x + x^2 \cosh x - 9x \sinh x\right), \\
 a_3^8 = & \left(\frac{\hbar}{\tilde{\omega}}\right)^4 \frac{1}{288x^2} \frac{1}{\sinh^3 \frac{x}{2}} \left(45x \cosh \frac{x}{2} - 6x^3 \cosh \frac{x}{2} - 45x \cosh \frac{3x}{2} \right. \\
 & \left. -432 \sinh \frac{x}{2} - 54x^2 \sinh \frac{x}{2} + 144 \sinh \frac{3x}{2} + 4x^2 \sinh \frac{3x}{2}\right), \tag{5A.7}
 \end{aligned}$$

$$\begin{aligned}
 a_{3'}^{10} = & \left(\frac{\hbar}{\tilde{\omega}}\right)^5 \frac{1}{2304x^3} \frac{1}{\sinh^4 \frac{x}{2}} \left(-3456 - 414x^2 - 6x^4 + 4608 \cosh x + \right. \\
 & 496x^2 \cosh x - 1152 \cosh 2x - 82x^2 \cosh 2x - 1008x \sinh x - \\
 & \left. 16x^3 \sinh x + 504x \sinh 2x + 5x^3 \sinh 2x\right). \tag{5A.8}
 \end{aligned}$$

Six of these integrals are the analogs of those in Eqs. (3.550). In addition there are the three integrals $a_2^6, a_3^8,$ and $a_{3'}^{10}$, corresponding to the three diagrams

(5A.9)

respectively, which are needed in Subsection 5.14.2. They have been calculated with zero Matsubara frequency in Eqs. (3D.8)–(3D.11).

In the low-temperature limit where $x = \Omega\hbar\beta \rightarrow \infty$, the x -dependent factors in Eqs. (5A.1)–(5A.8) converge towards the same constants (3D.13) as those with zero Matsubara frequency, and the same limiting relations hold as in Eqs. (3.553) and (3D.14).

The high-temperature limits $x \rightarrow 0$, however, are quite different from those in Eq. (3D.16). The present Feynman integrals all vanish rapidly for increasing temperatures. For L lines and V vertices, $\hbar\beta(1/\tilde{\omega})^{V-1} a_V^{2L}$ goes to zero like $\beta^V (\beta/12)^L$. The first V factors are due to the V -integrals over τ , the second are the consequence of the product of $n/2$ factors a^2 . Thus a_V^{2L} behaves like

$$a_V^{2L} \propto \left(\frac{\hbar}{\tilde{\omega}}\right)^L x^{V-1+L}. \tag{5A.10}$$

Indeed, the x -dependent factors in (5A.1)–(5A.8) vanish now like

$$\begin{aligned}
 & x/12, \quad x^3/720, \quad x^5/30240, \\
 & x^5/241920, \quad x^7/11404800, \quad 193x^8/47551795200, \\
 & x^4/30240, \quad x^6/1814400, \quad x^7/59875200, \tag{5A.11}
 \end{aligned}$$

respectively. When expanding (5A.1)–(5A.8) into a power series, the lowest powers cancel each other. For the temperature behavior of these Feynman integrals see Fig. 5.32. We have plotted the reduced Feynman integrals $\hat{a}_V^{2L}(x)$ in which the low-temperature behaviors (3.553) and (3D.14) have been divided out of a_V^{2L} .

Figure 5.32 Plot of the reduced Feynman integrals $\hat{a}_V^{2L}(x)$ as functions of $L/x = Lk_B T/\hbar\omega$. The integrals (3D.4)–(3D.11) are indicated by decreasing dash-lengths. Compare Fig. 3.16.

The integrals (5A.2) and (5A.3) for a_2^4 and a_3^6 can be obtained from the integral (5A.1) for a^2 via the operation

$$\frac{\hbar^n}{n!} \left(-\frac{\partial}{\partial \tilde{\omega}^2} \right)^n = \frac{\hbar^n}{n!} \left(-\frac{1}{2\tilde{\omega}} \frac{\partial}{\partial \tilde{\omega}} \right)^n, \tag{5A.12}$$

with $n = 1$ and $n = 2$, respectively. This is derived following the same steps as in Eqs. (3D.18)–(3D.20). The absence of the zero Matsubara frequency does not change the argument.

Also, as in Eqs. (5.195)–(3D.21), the same type of expansion allows us to derive the three integrals from the one-loop diagram (3.549).

Appendix 5B Proof of Scaling Relation for Extrema of W_N

Here we prove the scaling relation (5.215), according to which the derivative of the N th approximation W_N to the ground state energy can be written as [14]

$$\frac{d}{d\Omega} W_N^\Omega = \left(\frac{g}{\Omega^3} \right)^N p_N(\sigma), \tag{5B.1}$$

where $p_N(\sigma)$ is a polynomial of order N in the scaling variable $\sigma = \Omega(\Omega^2 - 1)/g$.

For the sake of generality, we consider an anharmonic oscillator with a potential gx^P whose power P is arbitrary. The ubiquitous factor $1/4$ accompanying g is omitted, for convenience. The energy eigenvalue of the ground state (or any excited state) has an N th order perturbation expansion

$$E_N(g) = \omega \sum_{l=0}^N E_l \left(\frac{g}{\omega^{(P+2)/2}} \right)^l, \tag{5B.2}$$

where E_l are rational numbers. After the replacement (5.188), the series is re-expanded at fixed r in powers of g up to order N , and we obtain

$$W_N^\Omega = \Omega \sum_{l=0}^N \varepsilon_l(\sigma) \left(\frac{g}{\Omega^{(P+2)/2}} \right)^l, \tag{5B.3}$$

with the re-expansion coefficients [compare (5.207)]

$$\varepsilon_l(\sigma) = \sum_{j=0}^l E_j \binom{(1 - \frac{P+2}{2}j)/2}{l-j} (-\sigma)^{l-j}. \tag{5B.4}$$

Here σ is a scaling variable for the potential gx^P generalizing (5.208) (note that it is four times as big as the previous σ , due to the different normalization of g):

$$\sigma \equiv \frac{\Omega^{(P-2)/2}(\Omega^2 - \omega^2)}{g}. \quad (5B.5)$$

We now show that the derivative $dW_N(g, \Omega)/d\Omega$ has the following scaling form generalizing (5B.1):

$$\frac{dW_N^\Omega}{d\Omega} = \left(\frac{g}{\Omega^{(P+2)/2}} \right)^N p_N(\sigma), \quad (5B.6)$$

where $p_N(\sigma)$ is the following polynomial of order N in the scaling variable σ :

$$\begin{aligned} p_N(\sigma) &= -2 \frac{d\varepsilon_{N+1}(\sigma)}{d\sigma} \\ &= 2 \sum_{j=0}^N E_j \left(\frac{(1 - \frac{P+2}{2}j)/2}{N+1-j} \right) (N+1-j) (-\sigma)^{N-j}. \end{aligned} \quad (5B.7)$$

The proof starts by differentiating (5B.3) with respect to Ω , yielding

$$\frac{dW_N^\Omega}{d\Omega} = \sum_{l=0}^N \left[\varepsilon_l(\sigma) - \frac{P+2}{2} l \varepsilon_l(\sigma) + \Omega \frac{d\varepsilon_l}{d\Omega} \right] \left(\frac{g}{\Omega^{(P+2)/2}} \right)^l. \quad (5B.8)$$

Using the chain rule of differentiation we see from (5B.4) that

$$\Omega \frac{d\varepsilon_l}{d\Omega} = \left[2 \frac{\Omega^{(P+2)/2}}{g} + \frac{P-2}{2} \sigma \right] \frac{d\varepsilon_l}{d\sigma}, \quad (5B.9)$$

and (5B.8) can be rewritten as

$$\frac{dW_N^\Omega}{d\Omega} = \sum_{l=0}^N \left[\left(1 - \frac{P+2}{2} l \right) \varepsilon_l(\sigma) + \left(2 \frac{\Omega^{(P+2)/2}}{g} + \frac{P-2}{2} \sigma \right) \frac{d\varepsilon_l}{d\sigma} \right] \left(\frac{g}{\Omega^{(P+2)/2}} \right)^l. \quad (5B.10)$$

After rearranging the sum, this becomes

$$\begin{aligned} \frac{dW_N^\Omega}{d\Omega} &= 2 \frac{d\varepsilon_0}{d\sigma} \left(\frac{g}{\Omega^{(P+2)/2}} \right)^{-1} \\ &+ \sum_{l=0}^{N-1} \left[\left(1 - \frac{P+2}{2} l \right) \varepsilon_l + \frac{P-2}{2} \sigma \frac{d\varepsilon_l}{d\sigma} + 2 \frac{d\varepsilon_{l+1}}{d\sigma} \right] \left(\frac{g}{\Omega^{(P+2)/2}} \right)^l \\ &+ \left[\left(1 - \frac{P+2}{2} N \right) \varepsilon_N + \frac{P-2}{2} \sigma \frac{d\varepsilon_N}{d\sigma} \right] \left(\frac{g}{\Omega^{(P+2)/2}} \right)^N. \end{aligned} \quad (5B.11)$$

The first term vanishes trivially since ε_0 happens to be independent of σ . The sum in the second line vanishes term by term:

$$\left(1 - \frac{P+2}{2} l \right) \varepsilon_l + \frac{P-2}{2} \sigma \frac{d\varepsilon_l}{d\sigma} + 2 \frac{d\varepsilon_{l+1}}{d\sigma} = 0, \quad l = 1 \dots N-1. \quad (5B.12)$$

To see this we form the derivative

$$2 \frac{d\varepsilon_{l+1}}{d\sigma} = 2 \sum_{j=0}^l E_j \left(\frac{(1 - \frac{P+2}{2}j)/2}{l+1-j} \right) (j-l-1) (-\sigma)^{l-j}, \quad (5B.13)$$

and use the identity

$$2 \binom{(1 - \frac{P+2}{2}j)/2}{l+1-j} = \frac{P-2}{j-l-1} \binom{(1 - \frac{P+2}{2}j)/2}{l-j} \quad (5B.14)$$

to rewrite (5B.13) as

$$2 \frac{d\varepsilon_{l+1}}{d\sigma} = \sum_{j=0}^l E_j \binom{(1 - \frac{P+2}{2}j)/2}{l-j} \left(\frac{P-2}{2}j + 2l - 1 \right) (-\sigma)^{l-j}, \quad (5B.15)$$

implying

$$\frac{P-2}{2} \sigma \frac{d\varepsilon_l}{d\sigma} = \sum_{j=0}^l E_j \binom{(1 - \frac{P+2}{2}j)/2}{l-j} \frac{P-2}{2} (l-j) (-\sigma)^{l-j}. \quad (5B.16)$$

By combining this with (5B.4), (5B.13), we obtain Eq. (5B.12) which proves that the second line in (5B.11) vanishes.

Thus we are left with the last term on the right-hand side of Eq. (5B.11). Using (5B.12) for $l = N$ leads to

$$\frac{dW_N^\Omega}{d\Omega} = -2 \left(\frac{g}{\Omega^{(P+2)/2}} \right)^N \frac{d\varepsilon_{N+1}(\sigma)}{d\sigma}. \quad (5B.17)$$

When expressing $d\varepsilon_{N+1}(\sigma)/d\sigma$ with the help of (5B.4), we arrive at

$$\frac{dW_N^\Omega}{d\Omega} = 2 \left(\frac{g}{\Omega^{(P+2)/2}} \right)^N \sum_{j=0}^N E_j \binom{(1 - \frac{P+2}{2}j)/2}{N+1-j} (N+1-j) (-\sigma)^{N-j}. \quad (5B.18)$$

This proves the scaling relation (5B.6) with the polynomial (5B.7).

The proof can easily be extended to physical quantities $Q_N(g)$ with a different physical dimension α , which have an expansion

$$Q_N(g) = \omega^\alpha \sum_{l=0}^N E_l \left(\frac{g}{\omega^{(P+2)/2}} \right)^l, \quad \alpha \neq 1, \quad (5B.19)$$

rather than (5B.2). In this case the quantity $[Q_N(g)]^{1/\alpha}$ has again an expansion like (5B.2). By rewriting $Q_N(g)$ as $\{[Q_N(g)]^{1/\alpha}\}^\alpha$ and forming the derivative using the chain rule we see that the derivative vanishes whenever the polynomial $p_N(\sigma)$ vanishes, which is formed from $[Q_N(g)]^{1/\alpha}$ as in Eq. (5B.7).

Appendix 5C Second-Order Shift of Polaron Energy

For brevity, we introduce the dimensionless variable $\rho \equiv \omega \Delta \tau$ and

$$F[\rho] \equiv -2\Gamma^2 \bar{G}^{\Omega, \Gamma}(\rho, 0). \quad (5C.1)$$

Going to natural units with $\hbar = M = \omega = 1$, Feynman's variational energy (5.395) takes the form

$$E_0 = \frac{3}{4\Gamma} (\Gamma - \Omega)^2 - \frac{1}{\sqrt{\pi}} \Gamma \int_0^\infty d\rho e^{-\rho} F^{-1/2}(\rho). \quad (5C.2)$$

The second-order correction (5.406) reads

$$\begin{aligned} \Delta E_0^{(2)} = & -\frac{41^2}{\pi} \Gamma^2 I + \frac{1}{2\Gamma\sqrt{\pi}} (\Gamma^2 - \Omega^2) \int_0^\infty d\rho e^{-\rho} F^{-1/2}(\rho) - \frac{3}{16\Gamma^3} (\Gamma^2 - \Omega^2)^2 \\ & - \frac{1}{4\sqrt{\pi}} (\Gamma^2 - \Omega^2) \int_0^\infty d\rho e^{-\rho} F^{-3/2}(\rho) \left\{ \left(1 + \frac{\Omega^2}{\Gamma} \right) (1 - e^{-\Gamma\rho}) + \frac{\Gamma^2 - \Omega^2}{\Gamma} \rho e^{-\Gamma\rho} \right\}, \end{aligned} \quad (5C.3)$$

where I denotes the integral

$$I = \frac{1}{4} \int_0^\infty \int_0^\infty \int_0^\infty d\rho_1 d\rho_2 d\rho_3 e^{-\rho_1 F^{-1/2}(\rho_1)} e^{-\rho_2 F^{-1/2}(\rho_2)} \left(\frac{\arcsin Q}{Q} - 1 \right), \quad (5C.4)$$

with

$$\begin{aligned} Q &= Q_1 \quad \text{for } \rho_3 - \rho_2 + \rho_1 \geq 0 \quad \text{and } \rho_3 - \rho_2 \geq 0, \\ Q &= Q_2 \quad \text{for } \rho_3 - \rho_2 + \rho_1 \geq 0 \quad \text{and } \rho_3 - \rho_2 < 0, \\ Q &= Q_3 \quad \text{for } \rho_3 - \rho_2 + \rho_1 < 0 \quad \text{and } \rho_3 - \rho_2 < 0, \end{aligned} \quad (5C.5)$$

and

$$Q_1 = \frac{1}{2} F^{-1/2}(\rho_1^2) F^{-1/2}(\rho_2^2) \frac{\Gamma^2 - \Omega^2}{\Gamma} e^{-\Gamma\rho_3} (1 - e^{-\Gamma\rho_1}) (e^{\Gamma\rho} - 1), \quad (5C.6)$$

$$\begin{aligned} Q_2 &= \frac{1}{2} F^{-1/2}(\rho_1) F^{-1/2}(\rho_2) \\ &\times \left\{ \frac{\Gamma^2 - \Omega^2}{\Gamma} \left[e^{-\Gamma(\rho_2 - \rho_3)} - e^{-\Gamma\rho_3} (1 + e^{-\Gamma(\rho_1 - \rho_2)} - e^{-\Gamma\rho_1}) \right] - 2\Omega^2(\rho_2 - \rho_3) \right\}, \end{aligned} \quad (5C.7)$$

$$\begin{aligned} Q_3 &= \frac{1}{2} F^{-1/2}(\rho_1) F^{-1/2}(\rho_2) \\ &\times \left\{ \frac{\Gamma^2 - \Omega^2}{\Gamma} \left[-e^{-\Gamma\rho_3} (1 - e^{-\Gamma\rho_1}) - e^{-\Gamma(\rho_2 - \rho_3)} (e^{\Gamma\rho_1} - 1) \right] - 2\Omega^2\rho_1 \right\}. \end{aligned} \quad (5C.8)$$

Notes and References

The first-order variational approximation to the effective classical partition function $V^{\text{eff cl}}(x_0)$ presented in this chapter was developed in 1983 by

R.P. Feynman and H. Kleinert, Phys. Rev. A **34**, 5080 (1986) (<http://www.physik.fu-berlin.de/~kleinert/159>).

For further development see:

H. Kleinert, Phys. Lett. A **118**, 195 (1986) (*ibid.*[http/148](http://148)); B **181**, 324 (1986) (*ibid.*[http/151](http://151));

The variational approach has solved some old problems in quantum crystals by extending in a simple way the classical methods into the quantum regime. See

- V.I. Yukalov, *Mosc. Univ. Phys. Bull.* **31**, 10-15 (1976);
 S. Liu, G.K. Horton, and E.R. Cowley, *Phys. Lett. A* **152**, 79 (1991);
 A. Cuccoli, A. Macchi, M. Neumann, V. Tognetti, and R. Vaia, *Phys. Rev. B* **45**, 2088 (1992).

The systematic extension of the variational approach was developed by

- H. Kleinert, *Phys. Lett. A* **173**, 332 (1993) (quant-ph/9511020).

See also

- J. Jaenicke and H. Kleinert, *Phys. Lett. A* **176**, 409 (1993) (*ibid.http/217*);
 H. Kleinert and H. Meyer, *Phys. Lett. A* **184**, 319 (1994) (hep-th/9504048).

A similar convergence mechanism was first observed within an order-dependent mapping technique in the seminal paper by

- R. Seznec and J. Zinn-Justin, *J. Math. Phys.* **20**, 1398 (1979).

For an introduction into various resummation procedures see

- C.M. Bender and S.A. Orszag, *Advanced Mathematical Methods for Scientists and Engineers*, McGraw-Hill, New York, 1978.

The proof of the convergence of the variational perturbation expansion to be given in Subsection 17.10.5 went through the following stages: First a weak estimate was found for the anharmonic integral:

- I.R.C. Buckley, A. Duncan, H.F. Jones, *Phys. Rev. D* **47**, 2554 (1993);
 C.M. Bender, A. Duncan, H.F. Jones, *Phys. Rev. D* **49**, 4219 (1994).

This was followed by a similar extension to the quantum-mechanical case:

- A. Duncan and H.F. Jones, *Phys. Rev. D* **47**, 2560 (1993);
 C. Arvanitis, H.F. Jones, and C.S. Parker, *Phys. Rev. D* **52**, 3704 (1995) (hep-ph/9502386);
 R. Guida, K. Konishi, and H. Suzuki, *Ann. Phys.* **241**, 152 (1995) (hep-th/9407027).

The exponentially fast convergence observed in the calculation of the strong-coupling coefficients of Table 5.9 was, however, not explained. The accuracy in the table was reached by working up to the order 251 with 200 digits in Ref. [13].

The analytic properties of the strong-coupling expansion were studied by

- C.M. Bender and T.T. Wu, *Phys. Rev.* **184**, 1231 (1969); *Phys. Rev. Lett.* **27**, 461 (1971); *Phys. Rev. D* **7**, 1620 (1973); *ibid. D* **7**, 1620 (1973);

 B. Simon, *Ann. Phys. (N.Y.)* **58**, 76 (1970); *Cargèse Lectures on Physics* (1970), D. Bessis ed., Gordon and Breach, New York 1972, Vol. 5, p. 383.

The problem of tunneling at low barriers (*sliding*) was solved by

- H. Kleinert, *Phys. Lett. B* **300**, 261 (1993) (*ibid.http/214*).

See also Chapter 17. Some of the present results are contained in

- H. Kleinert, *Pfadintegrale in Quantenmechanik, Statistik und Polymerphysik*, B.-I. Wissenschaftsverlag, Mannheim, 1993.

A variational approach to tunneling is also used in chemical physics:

- M.J. Gillan, *J. Phys. C* **20**, 362 (1987);
 G.A. Voth, D. Chandler, and W.H. Miller, *J. Chem. Phys.* **91**, 7749 (1990);
 G.A. Voth and E.V. O'Gorman, *J. Chem. Phys.* **94**, 7342 (1991);
 G.A. Voth, *Phys. Rev. A* **44**, 5302 (1991).

Variational approaches without the separate treatment of x_0 have been around in the literature

for some time:

- T. Barnes and G.I. Ghandour, Phys. Rev. D **22**, 924 (1980);
 B.S. Shaverdyan and A.G. Ushveridze, Phys. Lett. B **123**, 316 (1983);
 K. Yamazaki, J. Phys. A **17**, 345 (1984);
 H. Mitter and K. Yamazaki, J. Phys. A **17**, 1215 (1984);

- [34] The polaron problem is solved in detail in the textbook R.P. Feynman, *Statistical Mechanics*, Benjamin, New York, 1972, Chapter 8. Extensive numerical evaluations are found in T.D. Schultz, Phys. Rev. **116**, 526 (1959); See also M. Dineykhan, G.V. Efimov, G. Ganbold, and S.N. Nedelko, *Oscillator Representation in Quantum Physics*, Springer, Berlin, 1995. An excellent review article is J.T. Devreese, *Polarons*, Review article in Encyclopedia of Applied Physics, **14**, 383 (1996) (cond-mat/0004497). This article contains ample references on work concerning polarons in magnetic fields, for instance F.M. Peeters, J.T. Devreese, Phys. Stat. Sol. B **110**, 631 (1982); Phys. Rev. B **25**, 7281, 7302 (1982); Xiaoguang Wu, F.M. Peeters, J.T. Devreese, Phys. Rev. B **32**, 7964 (1985); F. Brosens and J.T. Devreese, Phys. Stat. Sol. B **145**, 517 (1988). For discussion of the validity of the Jensen-Peierls inequality (5.10) in the presence of a magnetic field, see J.T. Devreese and F. Brosens, Solid State Communs. **79**, 819 (1991); Phys. Rev. B **45**, 6459 (1992); Solid State Communs. **87**, 593 (1993); D. Larsen in *Landau Level Spectroscopy*, Vol. 1, G. Landwehr and E. Rashba (eds.), North Holland, Amsterdam, 1991, p. 109. The paper D. Larsen, Phys. Rev. B **32**, 2657 (1985) shows that the variational energy can lie lower than the exact energy. The review article by Devreese contains numerous references on bipolarons, small polarons, and polaronic excitations. For instance: J.T. Devreese, J. De Sitter, M.J. Goovaerts, Phys. Rev. B **5**, 2367 (1972); L.F. Lemmens, J. De Sitter, J.T. Devreese, Phys. Rev. B **8**, 2717 (1973); J.T. Devreese, L.F. Lemmens, J. Van Royen, Phys. Rev. B **15**, 1212 (1977); J. Thomchick, L.F. Lemmens, J.T. Devreese, Phys. Rev. B **14**, 1777 (1976); F.M. Peeters, Xiaoguang Wu, J.T. Devreese, Phys. Rev. B **34**, 1160 (1986); F.M. Peeters, J.T. Devreese, Phys. Rev. B **34**, 7246 (1986); B **35**, 3745 (1987); J.T. Devreese, S.N. Klimin, V.M. Fomin, F. Brosens, Solid State Communs. **114**, 305 (2000). There exists also a broad collection of articles in E.K.H. Salje, A.S. Alexandrov, W.Y. Liang (eds.), *Polarons and Bipolarons in High- T_c Superconductors and Related Materials*, Cambridge University Press, Cambridge, 1995. A generalization of the harmonic trial path integral (5.356), in which the exponential function $e^{-\Omega|\tau-\tau'|}$ at zero temperature is replaced by $f(|\tau-\tau'|)$, has been proposed by M. Saitoh, J. Phys. Soc. Japan. **49**, 878 (1980), and further studied by R. Rosenfelder and A.W. Schreiber, Phys. Lett. A **284**, 63 (2001) (cond-mat/0011332).

In spite of a much higher numerical effort, this generalization improves the ground state energy only by at most 0.1 % (the weak-coupling expansion coefficient -0.012346 in (5.396) is changed to -0.012598 , while the strong-coupling coefficients in (5.399) remain unchanged at this level of accuracy. For the effective mass, the lowest nontrivial weak-coupling coefficient of 1^2 in (5.402) is changed by 0.0252 % while the strong-coupling coefficients in (5.403) remain unchanged at this level of accuracy.

6

Path Integrals with Topological Constraints

The path integral representations of the time evolution amplitudes considered so far were derived for orbits $x(t)$ fluctuating in Euclidean space with Cartesian coordinates. Each coordinate runs from minus infinity to plus infinity. In many physical systems, however, orbits are confined to a topologically restricted part of a Cartesian coordinate system. This changes the quantum-mechanical completeness relation and with it the derivation of the path integral from the time-sliced time evolution operator in Section 2.1. We shall consider here only a point particle moving on a circle, in a half-space, or in a box. The path integral treatment of these systems is the prototype for any extension to more general topologies.

6.1 Point Particle on Circle

For a point particle on a circle, the orbits are specified in terms of an angular variable $\varphi(t) \in [0, 2\pi]$ subject to the topological constraint that $\varphi = 0$ and $\varphi = 2\pi$ be identical points.

The initial step in the derivation of the path integral for such a system is the same as before: The time evolution operator is decomposed into a product

$$\langle \varphi_b t_b | \varphi_a t_a \rangle = \langle \varphi_b | \exp \left[-\frac{i}{\hbar} (t_b - t_a) \hat{H} \right] | \varphi_a \rangle \equiv \langle \varphi_b | \prod_{n=1}^{N+1} \exp \left(-\frac{i}{\hbar} \epsilon \hat{H} \right) | \varphi_a \rangle. \quad (6.1)$$

The restricted geometry shows up in the completeness relations to be inserted between the factors on the right-hand side for $n = 1, \dots, N$:

$$\int_0^{2\pi} d\varphi_n |\varphi_n\rangle \langle \varphi_n| = 1. \quad (6.2)$$

If the integrand is singular at $\varphi = 0$, the integrations must end at an infinitesimal piece below 2π . Otherwise there is the danger of double-counting the contributions from the identical points $\varphi = 0$ and $\varphi = 2\pi$. The orthogonality relations on these intervals are

$$\langle \varphi_n | \varphi_{n-1} \rangle = \delta(\varphi_n - \varphi_{n-1}), \quad \varphi_n \in [0, 2\pi). \quad (6.3)$$

The δ -function can be expanded into a complete set of periodic functions on the circle:

$$\delta(\varphi_n - \varphi_{n-1}) = \sum_{m_n=-\infty}^{\infty} \frac{1}{2\pi} \exp[im_n(\varphi_n - \varphi_{n-1})]. \quad (6.4)$$

For a trivial system with no Hamiltonian, the scalar products (6.4) lead to the following representation of the transition amplitude:

$$(\varphi_b t_b | \varphi_a t_a)_0 = \prod_{n=1}^N \left[\int_0^{2\pi} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\sum_{m_n} \frac{1}{2\pi} \right] \exp \left[i \sum_{n=1}^{N+1} m_n (\varphi_n - \varphi_{n-1}) \right]. \quad (6.5)$$

We now introduce a Hamiltonian $H(p, \varphi)$. At each small time step, we calculate

$$\begin{aligned} (\varphi_n t_n | \varphi_{n-1} t_{n-1}) &= \langle \varphi_n | \exp \left[-\frac{i}{\hbar} \epsilon \hat{H}(p, \varphi) \right] | \varphi_{n-1} \rangle \\ &= \exp \left[-\frac{i}{\hbar} \epsilon \hat{H}(-i\hbar \partial_{\varphi_n}, \varphi_n) \right] \langle \varphi_n | \varphi_{n-1} \rangle. \end{aligned}$$

Replacing the scalar products by their spectral representation (6.4), this becomes

$$\begin{aligned} (\varphi_n t_n | \varphi_{n-1} t_{n-1}) &= \langle \varphi_n | \exp \left[-\frac{i}{\hbar} \epsilon \hat{H}(p, \varphi) \right] | \varphi_{n-1} \rangle \\ &= \exp \left[-\frac{i}{\hbar} \epsilon \hat{H}(-i\hbar \partial_{\varphi_n}, \varphi_n) \right] \sum_{m_n=-\infty}^{\infty} \frac{1}{2\pi} \exp[im_n(\varphi_n - \varphi_{n-1})]. \end{aligned} \quad (6.6)$$

By applying the operator in front of the sum to each term, we obtain

$$(\varphi_n t_n | \varphi_{n-1} t_{n-1}) = \sum_{m_n=-\infty}^{\infty} \frac{1}{2\pi} \exp \left[im_n(\varphi_n - \varphi_{n-1}) - \frac{i\epsilon}{\hbar} H(\hbar m_n, \varphi_n) \right]. \quad (6.7)$$

The total amplitude can therefore be written as

$$\begin{aligned} (\varphi_b t_b | \varphi_a t_a) &\approx \prod_{n=1}^N \left[\int_0^{2\pi} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\sum_{m_n=-\infty}^{\infty} \frac{1}{2\pi} \right] \\ &\quad \times \exp \left\{ i \sum_{n=1}^{N+1} \left[m_n (\varphi_n - \varphi_{n-1}) - \frac{1}{\hbar} \epsilon H(\hbar m_n, \varphi_n) \right] \right\}. \end{aligned} \quad (6.8)$$

This is the desired generalization of the original path integral from Cartesian to cyclic coordinates. As a consequence of the indistinguishability of $\varphi(t)$ and $\varphi(t) + 2\pi n$, the momentum integrations have turned into sums over integer numbers. The sums reflect the fact that the quantum-mechanical wave functions $(1/\sqrt{2\pi}) \exp(ip_\varphi \varphi/\hbar)$ are single-valued.

The discrete momenta enter into (6.8) via a ‘‘momentum step sum’’ rather than a proper path integral. At first sight, such an expression looks somewhat hard to deal with in practical calculations. Fortunately, it can be turned into a more comfortable

equivalent form, involving a proper continuous path integral. This is possible at the expense of a single additional infinite sum which guarantees the cyclic invariance in the variable φ . To find the equivalent form, we recall Poisson's formula (1.197),

$$\sum_{l=-\infty}^{\infty} e^{2\pi ikl} = \sum_{m=-\infty}^{\infty} \delta(k - m), \tag{6.9}$$

to make the right-hand side of (6.4) a periodic sum of δ -functions, so that (6.3) becomes

$$\langle \varphi_n | \varphi_{n-1} \rangle = \sum_{l=-\infty}^{\infty} \delta(\varphi_n - \varphi_{n-1} + 2\pi l). \tag{6.10}$$

A Fourier decomposition of the δ -functions yields

$$\langle \varphi_n | \varphi_{n-1} \rangle = \sum_{l=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dk_n}{2\pi} \exp[ik_n(\varphi_n - \varphi_{n-1}) + 2\pi i k_n l]. \tag{6.11}$$

Note that the right-hand side reduces to (6.4) when applying Poisson's summation formula (6.9) to the l -sum, which produces a sum of δ -functions for the integer values of $k_n = m_n = 0, \pm 1, \pm 2, \dots$. Using this expansion rather than (6.4), the amplitude (6.5) with no Hamiltonian takes the form

$$(\varphi_b t_b | \varphi_a t_a)_0 = \prod_{n=1}^N \left[\int_0^{2\pi} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dk_n}{2\pi} \sum_{l_n=-\infty}^{\infty} \right] e^{i \sum_{n=1}^{N+1} [k_n(\varphi_n - \varphi_{n-1}) + 2\pi k_n l_n]}. \tag{6.12}$$

In this expression, we observe that the sums over l_n can be absorbed into the variables φ_n by extending their range of integration from $[0, 2\pi)$ to $(-\infty, \infty)$. Only in the last sum $\sum_{l_{N+1}}$, this is impossible, and we arrive at

$$(\varphi_b t_b | \varphi_a t_a)_0 = \sum_{l=-\infty}^{\infty} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dk_n}{2\pi} \right] e^{i \sum_{n=1}^{N+1} k_n(\varphi_n - \varphi_{n-1} + 2\pi l \delta_{n,N+1})}. \tag{6.13}$$

The right-hand side looks just like an $\hat{H} \equiv 0$ -amplitude of an ordinary particle which would read

$$(\varphi_b t_b | \varphi_a t_a)_{0, \text{noncyclic}} = \prod_{n=1}^N \left[\int_{-\infty}^{\infty} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dk_n}{2\pi} \right] e^{i \sum_{n=1}^{N+1} k_n(\varphi_n - \varphi_{n-1})}. \tag{6.14}$$

The amplitude (6.13) differs from this by the sum over paths running over all periodic repetitions of the final point $\varphi_b + 2\pi n, t_b$. The amplitude (6.13) may therefore be written as a sum over all periodically repeated final points of the amplitude (6.14):

$$(\varphi_b t_b | \varphi_a t_a)_0 = \sum_{l=-\infty}^{\infty} (\varphi_b + 2\pi l, t_b | \varphi_a t_a)_{0, \text{noncyclic}}. \tag{6.15}$$

In each term on the right-hand side, the Hamiltonian can be inserted as usual, and we arrive at the time-sliced formula

$$\begin{aligned}
 (\varphi_b t_b | \varphi_a t_a) &\approx \sum_{l=-\infty}^{\infty} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} d\varphi_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \\
 &\times \exp \left\{ \frac{i}{\hbar} \sum_{n=1}^{N+1} [p_n(\varphi_n - \varphi_{n-1} + 2\pi l \delta_{n,N+1}) - \epsilon H(p_n, \varphi_n)] \right\}. \quad (6.16)
 \end{aligned}$$

In the continuum limit, this tends to the path integral

$$(\varphi_b t_b | \varphi_a t_a) \xrightarrow{\epsilon \rightarrow 0} \sum_{l=-\infty}^{\infty} \int_{\varphi_a + 2\pi l}^{\varphi_b + 2\pi l} \mathcal{D}\varphi(t) \int \frac{\mathcal{D}p(t)}{2\pi\hbar} \exp \left\{ \frac{i}{\hbar} \int_{t_a}^{t_b} dt [p\dot{\varphi} - H(p, \varphi)] \right\}. \quad (6.17)$$

The way in which this path integral has replaced the sum over all paths on the circle $\varphi \in [0, 2\pi)$ by the sum over all paths with the same action on the entire φ -axis is illustrated in Fig. 6.1.

As an example, consider a free particle moving on a circle with a Hamiltonian

$$H(p, \varphi) = \frac{p^2}{2M}. \quad (6.18)$$

The ordinary noncyclic path integral is

$$(\varphi_b t_b | \varphi_a t_a)_{\text{noncyclic}} = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \exp \left[\frac{i M (\varphi_b - \varphi_a)^2}{\hbar 2 (t_b - t_a)} \right]. \quad (6.19)$$

Using Eq. (6.15), the cyclic amplitude is given by the periodic Gaussian

$$(\varphi_b t_b | \varphi_a t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \sum_{l=-\infty}^{\infty} \exp \left[\frac{i M (\varphi_b - \varphi_a + 2\pi l)^2}{\hbar 2 (t_b - t_a)} \right]. \quad (6.20)$$

The same amplitude could, of course, have been obtained by a direct quantum-mechanical calculation based on the wave functions

$$\psi_m(\varphi) = \frac{1}{\sqrt{2\pi}} e^{im\varphi} \quad (6.21)$$

and the energy eigenvalues

$$H = \frac{\hbar^2}{2M} m^2. \quad (6.22)$$

Within operator quantum mechanics, we find

$$\begin{aligned}
 (\varphi_b t_b | \varphi_a t_a) &= \langle \varphi_b | \exp \left[-\frac{i}{\hbar} (t_b - t_a) \hat{H} \right] | \varphi_a \rangle \\
 &= \sum_{m=-\infty}^{\infty} \psi_m(\varphi_b) \psi_m^*(\varphi_a) \exp \left[-\frac{i \hbar^2 m^2}{2M} (t_b - t_a) \right] \\
 &= \sum_{m=-\infty}^{\infty} \frac{1}{2\pi} \exp \left[im(\varphi_b - \varphi_a) - i \frac{\hbar m^2}{2M} (t_b - t_a) \right]. \quad (6.23)
 \end{aligned}$$

Figure 6.1 Path with 3 jumps from 2π to 0 at $t_{j_1}, t_{j_2}, t_{j_3}$, and with one jump from 0 to 2π at $t_{\bar{j}_1}$. It can be drawn as a smooth path in the *extended zone scheme*, arriving at $\varphi^{(n, \bar{n})} = \varphi_b + (n - \bar{n})2\pi$, where n and \bar{n} count the number of jumps of the first and the second type, respectively.

If the sum over m is converted into an integral over p and a dual l -sum via Poisson's formula (6.9), this coincides with the previous result:

$$\begin{aligned}
 (\varphi_b t_b | \varphi_a t_a) &= \sum_{l=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} \exp \left\{ \frac{i}{\hbar} \left[p(\varphi_b - \varphi_a + 2\pi l) - \frac{p^2}{2M}(t_b - t_a) \right] \right\} \\
 &= \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \sum_{l=-\infty}^{\infty} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(\varphi_b - \varphi_a + 2\pi l)^2}{t_b - t_a} \right]. \quad (6.24)
 \end{aligned}$$

6.2 Infinite Wall

In the case of an infinite wall, only a half-space, say $x = r > 0$, is accessible to the particle, and the completeness relation reads

$$\int_0^{\infty} dr |r\rangle \langle r| = 1. \quad (6.25)$$

For singular integrands, the origin has to be omitted from the integration. The orthogonality relation is

$$\langle r | r' \rangle = \delta(r - r'); \quad r, r' > 0. \quad (6.26)$$

Given a free particle moving in such a geometry, we want to calculate

$$(r_b t_b | r_a t_a) = \langle r_b | \prod_{n=1}^{N+1} \exp \left(-\frac{i}{\hbar} \hat{H} \epsilon \right) | r_a \rangle. \quad (6.27)$$

As usual, we insert N completeness relations between the $N + 1$ factors. In the case of a vanishing Hamiltonian, the amplitude (6.27) becomes

$$(r_b t_b | r_a t_a)_0 = \prod_{n=1}^N \left[\int_0^\infty dr_n \right] \prod_{n=1}^{N+1} \langle r_n | r_{n-1} \rangle = \langle r_b | r_a \rangle. \quad (6.28)$$

For each scalar product $\langle r_n | r_{n-1} \rangle = \delta(r_n - r_{n-1})$, we substitute its spectral representation appropriate to the infinite-wall boundary at $r = 0$. It consists of a superposition of the free-particle wave functions vanishing at $r = 0$:

$$\begin{aligned} \langle r | r' \rangle &= 2 \int_0^\infty \frac{dk}{\pi} \sin kr \sin kr' \\ &= \int_{-\infty}^\infty \frac{dk}{2\pi} [\exp ik(r - r') - \exp ik(r + r')] = \delta(r - r') - \delta(r + r'). \end{aligned} \quad (6.29)$$

This Fourier representation does a bit more than what we need. In addition to the δ -function at $r = r'$, there is also a δ -function at the unphysical reflected point $r = -r'$. The reflected point plays a similar role as the periodically repeated points in the representation (6.11). For the same reason as before, we retain the reflected points in the formula as though r' were permitted to become zero or negative. Thus we rewrite the Fourier representation (6.29) as

$$\langle r | r' \rangle = \sum_{x=\pm r} \int_{-\infty}^\infty \frac{dp}{2\pi\hbar} \exp \left[\frac{i}{\hbar} p(x - x') + i\pi(\sigma(x) - \sigma(x')) \right]_{x'=r'}, \quad (6.30)$$

where

$$\sigma(x) \equiv \Theta(-x) \quad (6.31)$$

with the Heaviside function $\Theta(x)$ of Eq. (1.313). For symmetry reasons, it is convenient to liberate both the initial and final positions r and r' from their physical half-space and to introduce the localized states $|x\rangle$ whose scalar product exists on the entire x -axis:

$$\begin{aligned} \langle x | x' \rangle &= \sum_{x''=\pm x} \int_{-\infty}^\infty \frac{dp}{2\pi\hbar} \exp \left[\frac{i}{\hbar} p(x'' - x') + i\pi(\sigma(x'') - \sigma(x')) \right] \\ &= \delta(x - x') - \delta(x + x'). \end{aligned} \quad (6.32)$$

With these states, we write

$$\langle r | r' \rangle = \langle x | x' \rangle_{|x=r, x'=r'}. \quad (6.33)$$

We now take the trivial transition amplitude with zero Hamiltonian

$$(r_b t_b | r_a t_a)_0 = \delta(r_b - r_a), \quad (6.34)$$

extend it with no harm by the reflected δ -function

$$(r_b t_b | r_a t_a)_0 = \delta(r_b - r_a) - \delta(r_b + r_a), \quad (6.35)$$

and factorize it into many time slices:

$$(r_b t_b | r_a t_a)_0 = \prod_{n=1}^N \left[\int_0^\infty dr_n \right] \prod_{n=1}^{N+1} \left[\sum_{x_n = \pm r_n} (x_n \epsilon | x_{n-1} 0)_0 \right] \quad (6.36)$$

($r_b = r_{N+1}, r_a = r_0$), where the trivial amplitude of a single slice is

$$(x_n \epsilon | x_{n-1} 0)_0 = \langle x_n | x_{n-1} \rangle, \quad x \in (-\infty, \infty). \quad (6.37)$$

With the help of (6.32), this can be written as

$$(r_b t_b | r_a t_a)_0 = \prod_{n=1}^N \left[\int_0^\infty dr_n \right] \prod_{n=1}^{N+1} \left[\sum_{x_n = \pm r_n} \int_{-\infty}^\infty \frac{dp_n}{2\pi\hbar} \right] \\ \times \exp \left\{ \sum_{n=1}^{N+1} \left[\frac{i}{\hbar} p(x_n - x_{n-1}) + i\pi(\sigma(x_n) - \sigma(x_{n-1})) \right] \right\}. \quad (6.38)$$

The sum over the reflected points $x_n = \pm r_n$ is now combined, at each n , with the integral $\int_0^\infty dr_n$ to form an integral over the entire x -axis, including the unphysical half-space $x < 0$. Only the last sum cannot be accommodated in this way, so that we obtain the path integral representation for the trivial amplitude

$$(r_b t_b | r_a t_a)_0 = \sum_{x_b = \pm r_b} \prod_{n=1}^N \left[\int_{-\infty}^\infty dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^\infty \frac{dp_n}{2\pi\hbar} \right] \\ \times \exp \left\{ \sum_{n=1}^{N+1} \left[\frac{i}{\hbar} p(x_n - x_{n-1}) + i\pi(\sigma(x_n) - \sigma(x_{n-1})) \right] \right\}. \quad (6.39)$$

The measure of this path integral is now of the conventional type, integrating over all paths which fluctuate through the entire space. The only special feature is the final symmetrization in $x_b = \pm r_b$.

It is instructive to see in which way the final symmetrization together with the phase factor $\exp[i\pi\sigma(x)] = \pm 1$ eliminates all the wrong paths in the extended space, i.e., those which cross the origin into the unphysical subspace. This is illustrated in Fig. 6.2. Note that having assumed $x_a = r_a > 0$, the initial phase $\sigma(x_a)$ can be omitted. We have kept it merely for symmetry reasons.

In the continuum limit, the exponent corresponds to an action

$$\mathcal{A}_0^\sigma[p, x] = \int_{t_a}^{t_b} dt [p\dot{x} + \hbar\pi\partial_t\sigma(x)] \equiv \mathcal{A}_0[p, x] + \mathcal{A}_{\text{topol}}^\sigma. \quad (6.40)$$

The first term is the usual canonical expression in the absence of a Hamiltonian. The second term is new. It is a pure boundary term:

$$\mathcal{A}_{\text{topol}}^\sigma[x] = \hbar\pi(\sigma(x_b) - \sigma(x_a)), \quad (6.41)$$

which keeps track of the topology of the half space $x > 0$ embedded in the full space $x \in (-\infty, \infty)$. This is why the action carries the subscript “topol”.

Figure 6.2 Illustration of path counting near reflecting wall. Each path touching the wall once is canceled by a corresponding path of equal action crossing the wall once into the unphysical regime (the path is mirror-reflected after the crossing). The phase factor $\exp[i\pi\sigma(x_b)]$ provides for the opposite sign in the path integral. Only paths not touching the wall at all cannot be canceled in the path integral.

The topological action (6.41) can be written formally as a local coupling of the velocity at the origin:

$$\mathcal{A}_{\text{topol}}^\sigma[x] = -\pi\hbar \int_{t_a}^{t_b} dt \dot{x}(t) \delta(x(t)). \quad (6.42)$$

This follows directly from

$$\sigma(x_b) - \sigma(x_a) = \int_{x_a}^{x_b} dx \sigma'(x) = \int_{x_a}^{x_b} dx \Theta'(-x) = - \int_{x_a}^{x_b} dx \delta(x). \quad (6.43)$$

Consider now a free point particle in the right half-space with the usual Hamiltonian

$$H = \frac{p^2}{2M}. \quad (6.44)$$

The action reads

$$\mathcal{A}[p, x] = \int_{t_a}^{t_b} dt [p\dot{x} - p^2/2M - \hbar\pi\dot{x}(t)\delta(x(t))], \quad (6.45)$$

and the time-sliced path integral looks like (6.39), except for additional energy terms $-p_n^2/2M$ in the action. Since the new topological term is a pure boundary term, all the extended integrals in (6.39) can be evaluated right away in the same way as for a free particle in the absence of an infinite wall. The result is

$$\begin{aligned} (r_b t_b | r_a t_a) &= \sum_{x_b = \pm r_b} \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \\ &\times \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} + i\pi(\sigma(x_b) - \sigma(x_a)) \right] \\ &= \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \left\{ \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(r_b - r_a)^2}{t_b - t_a} \right] - (r_b \rightarrow -r_b) \right\} \end{aligned} \quad (6.46)$$

with $x_a = r_a$.

This is indeed the correct result: Inserting the Fourier transform of the Gaussian (Fresnel) distribution we see that

$$\begin{aligned} (r_b t_b | r_a t_a) &= \int_{-\infty}^{\infty} \frac{dp}{2\pi\hbar} \left\{ \exp \left[\frac{i}{\hbar} p(r_b - r_a) \right] - (r_b \rightarrow -r_b) \right\} e^{-ip^2(t_b - t_a)/2M\hbar} \\ &= 2 \int_0^{\infty} \frac{dp}{2\pi\hbar} \sin(pr_b/\hbar) \sin(pr_a/\hbar) \exp \left[-\frac{i}{\hbar} \frac{p^2}{2M} (t_b - t_a) \right], \end{aligned} \quad (6.47)$$

which is the usual spectral representation of the time evolution amplitude.

Note that the first part of (6.46) may be written more symmetrically as

$$(r_b t_b | r_a t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \frac{1}{2} \sum_{\substack{x_a = \pm r_a \\ x_b = \pm r_b}} \exp \left[\frac{i}{\hbar} \frac{M}{2} \frac{(x_b - x_a)^2}{t_b - t_a} + i\pi(\sigma(x_b) - \sigma(x_a)) \right]. \quad (6.48)$$

In this form, the phase factors $e^{i\pi\sigma(x)}$ are related to what may be considered as even and odd “spherical harmonics” in one dimension [more after (9.60)]

$$Y_{e,o}(\hat{x}) = \frac{1}{\sqrt{2}} (\Theta(x) \pm \Theta(-x)),$$

namely,

$$Y_e(\hat{x}) = \frac{1}{\sqrt{2}}, \quad Y_o(\hat{x}) = \frac{1}{\sqrt{2}} e^{i\pi\sigma(x)}. \quad (6.49)$$

The amplitude (6.48) is therefore simply the odd “partial wave” of the free-particle amplitude

$$(r_b t_b | r_a t_a) = \sum_{\substack{\hat{x}_b, \hat{x}_a \\ |\hat{x}_b| = r_b, |\hat{x}_a| = r_a}} Y_o^*(\hat{x}_b) \langle x_b t_b | x_a t_a \rangle Y_o(\hat{x}_a), \quad (6.50)$$

which is what we would also have obtained from Schrödinger quantum mechanics.

6.3 Point Particle in Box

If a point particle is confined between two infinitely high walls in the interval $x \in (0, d)$, we speak of a *particle in a box*.¹ The box is a geometric constraint. Since the wave functions vanish at the walls, the scalar product between localized states is given by the quantum-mechanical orthogonality relation for $r \in (0, d)$:

$$\langle r | r' \rangle = \frac{2}{d} \sum_{k_\nu > 0} \sin k_\nu r \sin k_\nu r', \quad (6.51)$$

where k_ν runs over the discrete positive momenta

$$k_\nu = \frac{\pi}{d} \nu, \quad \nu = 1, 2, 3, \dots \quad (6.52)$$

We can write the restricted sum in (6.51) also as a sum over all momenta k_ν with $\nu = 0, \pm 1, \pm 2, \dots$: ref(6.51)
lab(6.46)
est(6.51)

$$\langle r|r' \rangle = \frac{1}{2d} \sum_{k_\nu} \left[e^{ik_\nu(r-r')} - e^{ik_\nu(r+r')} \right]. \tag{6.53}$$

With the help of the Poisson summation formula (6.9), the right-hand side is converted into an integral and an auxiliary sum:

$$\langle r|r' \rangle = \sum_{l=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dk}{2\pi} \left[e^{ik(r-r'+2dl)} - e^{ik(r+r'+2dl)} \right]. \tag{6.54}$$

Using the potential $\sigma(x)$ of (6.31), this can be re-expressed as

$$\langle r|r' \rangle = \sum_{x=\pm r} \sum_{l=-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{dk}{2\pi} e^{ik(x-x'+2dl)+i\pi(\sigma(x)-\sigma(x'))}. \tag{6.55}$$

The trivial path integral for the time evolution amplitude with a zero Hamiltonian is again obtained by combining a sequence of scalar products (6.51):

$$\begin{aligned} (r_b t_b | r_a t_a)_0 &= \prod_{n=1}^N \left[\int_0^d dr_n \right] \langle r_n | r_{n-1} \rangle \\ &= \prod_{n=1}^N \left[\int_0^d dr_n \right] \prod_{n=1}^{N+1} \frac{2}{d} \sum_{k_\nu} \sin k_{\nu_n} r_n \sin k_{\nu_{n-1}} r_{n-1}. \end{aligned} \tag{6.56}$$

The alternative spectral representation (6.55) allows us to extend the restricted integrals over x_n and sums over k_ν to complete phase space integrals, and we may write

$$(r_b t_b | r_a t_a)_0 = \sum_{x_b=\pm r_b} \sum_{l=-\infty}^{\infty} \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n}{2\pi\hbar} \right] \exp \left(\frac{i}{\hbar} \mathcal{A}_0^N \right), \tag{6.57}$$

with the time-sliced $H \equiv 0$ -action:

$$\mathcal{A}_0^N = \sum_{n=1}^{N+1} [p_n(x_n - x_{n-1}) + \hbar\pi(\sigma(x_n) - \sigma(x_{n-1}))]. \tag{6.58}$$

The final x_b is summed over all periodically repeated endpoints $r_b + 2dl$ and their reflections $-r_b + 2dl$.

We now add dynamics to the above path integral by introducing some Hamiltonian $H(p, x)$, so that the action reads

$$\mathcal{A} = \int_{t_a}^{t_b} dt [p\dot{x} - H(p, x) - \hbar\pi\dot{x}\delta(x)]. \tag{6.59}$$

The amplitude is written formally as the path integral

$$(r_b t_b | r_a t_a) = \sum_{l=-\infty}^{\infty} \sum_{x_b=\pm r_b+2dl} \int \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left(\frac{i}{\hbar} \mathcal{A} \right). \tag{6.60}$$

Figure 6.3 Illustration of path counting in a box. A path reflected once on the upper and once on the lower wall of the box is eliminated by a path with the same action running to $x_b^{(1)}$ and to $\bar{x}_b^{(0)}, \bar{x}_b^{(1)}$. The latter receive a negative sign in the path integral from the phase factor $\exp[i\pi\sigma(x_b)]$. Only paths remaining completely within the walls have no partner for cancellation.

Figure 6.4 A particle in a box is topologically equivalent to a particle on a circle with an infinite wall at one point.

In the time-sliced version, the action is

$$\mathcal{A}^N = \mathcal{A}_0^N - \epsilon \sum_{n=1}^{N+1} H(p_n, x_n). \tag{6.61}$$

The way in which the sum over the final positions $x_b = \pm r_b + 2dl$ together with the phase factor $\exp[i\pi\sigma(x_b)]$ eliminates the unphysical paths is illustrated in Fig. 6.3. The mechanism is obviously a combination of the previous two. A particle in a box of length d behaves like a particle on a circle of circumference $2d$ with a periodic boundary condition, containing an infinite wall at one point. This is illustrated in Fig. 6.4. The periodicity in $2d$ selects the momenta

$$k_\nu = (\pi/d)\nu, \quad \nu = 1, 2, 3, \dots,$$

as it should.

¹See W. Janke and H. Kleinert, Lett. Nuovo Cimento 25, 297 (1979) (<http://www.physik.fu-berlin.de/~kleinert/64>).

For a free particle with $H = p^2/2M$, the integrations over x_n, p_n can be done as usual and we obtain the amplitude ($x_a = r_a$)

$$(r_b t_b | r_a t_a) = \sum_{l=-\infty}^{\infty} \sum_{x_b = \pm r_b + 2dl} \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/M}} \left[e^{\frac{iM}{\hbar} \frac{(x_b - x_a + 2dl)^2}{t_b - t_a}} - (x_b \rightarrow -x_b) \right]. \quad (6.62)$$

A Fourier transform and an application of Poisson's formula (6.9) shows that this is, of course, equal to the quantum-mechanical expression

$$\begin{aligned} (r_b t_b | r_a t_a) &= \langle r_b | \exp \left[-\frac{i}{\hbar} (t_b - t_a) \hat{H} \right] | r_a \rangle \\ &= \frac{2}{d} \sum_{\nu=1}^{\infty} \sin k_{\nu} r_b \sin k_{\nu} r_a \exp \left[-i\hbar \frac{k_{\nu}^2}{2M} (t_b - t_a) \right]. \end{aligned} \quad (6.63)$$

In analogy with the discussion in Section 2.6, we identify in the exponentials the eigenvalues of the energy levels labeled by $\nu - 1 = 0, 1, 2, \dots$:

$$E^{(\nu-1)} = \frac{\hbar^2 k_{\nu}^2}{2M}, \quad \nu = 1, 2, 3, \dots \quad (6.64)$$

The factors in front determine the wave functions associated with these energies:

$$\psi^{(\nu-1)}(x) = \frac{2}{d} \sin k_{\nu} x. \quad (6.65)$$

6.4 Strong-Coupling Theory for Particle in Box

The strong-coupling theory developed in Chapter 5 opens up the possibility of treating quantum-mechanical systems with hard-wall potentials via perturbation theory. After converting divergent weak-coupling expansions into convergent strong-coupling expansions, the strong-coupling limit of a function can be evaluated from its weak-coupling expansion with any desired accuracy. Due to the combination with the variational procedure, new classes of physical systems become accessible to perturbation theory. For instance, the important problem of the pressure exerted by a stack of membranes upon enclosing walls has been solved by this method.²

Here we illustrate the working of that theory for the system treated in the previous section, the point particle in a one-dimensional box.

This is just a quantum-mechanical exercise for the treatment of physically more interesting problems. The ground state energy of this system has, according to Eq. (6.64), the value $E^{(0)} = \pi^2/2d^2$. For simplicity, we shall now use natural units in which we can omit Planck and Boltzmann constants everywhere, setting them equal to unity: $\hbar = 1, k_B = 1$. We shall now demonstrate how this result is found via strong-coupling theory from a perturbation expansion.

²See Notes and References.

6.4.1 Partition Function

The discussion becomes simplest by considering the quantum statistical partition function of the particle. It is given by the Euclidean path integral (always in natural units)

$$Z = \int \mathcal{D}u(\tau) e^{\frac{1}{2} \int_0^{\hbar\beta} d\tau (\partial u)^2}, \quad (6.66)$$

where the shifted particle coordinate $u(\tau) \equiv x(\tau) - d/2$ is restricted to the symmetric interval $-d/2 \leq u(\tau) \leq d/2$. Since such a hard-wall restriction is hard to treat analytically in (6.66), we make the hard-walls soft by adding to the Euclidean action E in the exponent of (6.66) a potential term diverging near the walls. Thus we consider the auxiliary Euclidean action

$$\mathcal{A}_e = \frac{1}{2} \int_0^{\hbar\beta} d\tau \left\{ [\partial u(\tau)]^2 + V(u(\tau)) \right\}, \quad (6.67)$$

where $V(u)$ is given by

$$V(u) = \frac{\omega^2}{2} \left(\frac{d}{\pi} \tan \frac{\pi u}{d} \right)^2 = \frac{\omega^2}{2} \left(u^2 + \frac{2}{3} g u^4 + \dots \right). \quad (6.68)$$

On the right-hand side we have introduced a parameter $g \equiv \pi^2/d^2$.

6.4.2 Perturbation Expansion

The expansion of the potential in powers of g can now be treated perturbatively, leading to an expansion of Z around the harmonic part of the partition function. In this, the integrations over $u(\tau)$ run over the entire u -axis, and can be integrated out as described in Section 2.15. The result is [see Eq. (2.489)]

$$Z_\omega = e^{-(1/2)\text{Tr} \log(\partial^2 + \omega^2)}. \quad (6.69)$$

For $\beta \rightarrow \infty$, the exponent gives a free energy density $F = -\beta^{-1} \log Z$ equal to the ground state energy of the harmonic oscillator

$$F_\omega = \frac{\omega}{2}. \quad (6.70)$$

The treatment of the interaction terms can be organized in powers of g , and give rise to an expansion of the free energy with the generic form

$$F = F_\omega + \omega \sum_{k=1}^{\infty} a_k \left(\frac{g}{\omega} \right)^k. \quad (6.71)$$

The calculation of the coefficients a_k in this expansion proceeds as follows. First we expand the potential in (6.67) to identify the power series for the interaction energy

$$\begin{aligned} \mathcal{A}_e^{\text{int}} &= \frac{\omega^2}{2} \int d\tau \left(g v_4 u^4 + g^2 v_6 u^6 + g^3 v_8 u^8 + \dots \right) \\ &= \frac{\omega^2}{2} \sum_{k=1}^{\infty} \int d\tau g^k v_{2k+2} [u^2(\tau)]^{k+1}, \end{aligned} \quad (6.72)$$

with coefficients

$$\begin{aligned}
 v_4 &= \frac{2}{3}, \quad v_6 = \frac{17}{45}, \quad v_8 = \frac{62}{315}, \quad v_{10} = \frac{1382}{14175}, \quad v_{12} = \frac{21844}{467775}, \quad v_{14} = \frac{929569}{42567525}, \\
 v_{16} &= \frac{6404582}{638512875}, \quad v_{18} = \frac{443861162}{97692469875}, \quad v_{20} = \frac{18888466084}{9280784638125}, \quad v_{22} = \frac{113927491862}{126109485376875}, \\
 v_{24} &= \frac{58870668456604}{147926426347074375}, \quad v_{26} = \frac{8374643517010684}{48076088562799171875}, \quad v_{28} = \frac{689005380505609448}{9086380738369043484375}, \\
 v_{30} &= \frac{129848163681107301953}{3952575621190533915703125}, \quad v_{32} = \frac{1736640792209901647222}{122529844256906551386796875}, \\
 v_{34} &= \frac{418781231495293038913922}{68739242628124575327993046875}, \quad \dots \quad (6.73)
 \end{aligned}$$

The interaction terms $\int d\tau [u^2(\tau)]^{k+1}$ and their products are expanded according to Wick's rule in Section 3.10 into sums of products of harmonic two-point correlation functions

$$\langle u(\tau_1)u(\tau_2) \rangle = \int \frac{dk}{2\pi} \frac{e^{ik(\tau_1-\tau_2)}}{k^2 + \omega^2} = \frac{e^{-\omega|\tau_1-\tau_2|}}{2\omega}. \quad (6.74)$$

Associated local expectation values are $\langle u^2 \rangle = 1/2\omega$, and

$$\begin{aligned}
 \langle u\partial u \rangle &= \int \frac{dk}{2\pi} \frac{k}{k^2 + \omega^2} = 0 \\
 \langle \partial u\partial u \rangle &= \int \frac{dk}{2\pi} \frac{k^2}{k^2 + \omega^2} = -\frac{\omega}{2}, \quad (6.75)
 \end{aligned}$$

where the last integral is calculated using dimensional regularization in which $\int dk k^\alpha = 0$ for all α . The Wick contractions are organized with the help of the Feynman diagrams as explained in Section 3.20. Only the connected diagrams contribute to the free energy density. The graphical expansion of free energy up to four loops is

$$\begin{aligned}
 F &= \frac{\omega}{2} + \left(\frac{\omega^2}{2}\right) \left\{ gv_4 \text{3 loops} + g^2 v_6 \text{15 loops} + g^3 v_8 \text{105 loops} \right\} \\
 &\quad - \frac{1}{2!} \left(\frac{\omega^2}{2}\right)^2 \left\{ g^2 v_4^2 [72 \text{3 loops} + 24 \text{4 loops}] + g^3 2v_4 v_6 [540 \text{3 loops} + 360 \text{4 loops}] \right\} \\
 &\quad + \frac{1}{3!} \left(\frac{\omega^2}{2}\right)^3 g^3 v_4^3 \left\{ 2592 \text{3 loops} + 1728 \text{4 loops} + 3456 \text{5 loops} + 1728 \text{6 loops} \right\}. \quad (6.76)
 \end{aligned}$$

Note different numbers of loops contribute to the terms of order g^n . The calculation of the diagrams in Eq. (6.76) is simplified by the factorization property: If a diagram consists of two subdiagrams touching each other at a single vertex, the associated Feynman integral factorizes into those of the subdiagrams. In each diagram, the last t -integral yields an overall factor β , due to translational invariance along the t -axis, the others produce a factor $1/\omega$. Using the explicit expression (6.75) for the lines in the diagrams, we find the following values for the Feynman integrals:

$$\text{3 loops} = \beta \frac{1}{16\omega^5}, \quad \text{4 loops} = \beta \frac{1}{64\omega^8},$$

$$\begin{aligned}
\text{⊖} &= \beta \frac{1}{32\omega^5}, & \text{⊖} &= \beta \frac{3}{128\omega^8}, \\
\text{⊖} &= \beta \frac{1}{32\omega^6}, & \text{⊖} &= \beta \frac{5}{8 \cdot 64\omega^8}, \\
\text{⊖} &= \beta \frac{1}{32\omega^6}, & \text{⊖} &= \beta \frac{3}{8 \cdot 64\omega^8}.
\end{aligned} \tag{6.77}$$

Adding all contributions in (6.76), we obtain up to the order g^3 :

$$F_3 = \omega \left\{ \frac{1}{2} + \frac{3}{8}v_4 \left(\frac{g}{\omega} \right) + \left[\frac{15}{16}v_6 - \frac{21}{32}v_4^2 \right] \left(\frac{g}{\omega} \right)^2 + \left[\frac{105}{32}v_8 - \frac{45}{8}v_4 v_6 + \frac{333}{128}v_4^3 \right] \left(\frac{g}{\omega} \right)^3 \right\}, \tag{6.78}$$

which has the generic form (6.71).

We can go to higher orders by extending the Bender-Wu recursion relation (3C.20) for the ground state energy of the quartic anharmonic oscillator as follows:

$$\begin{aligned}
2p' C_n^{p'} &= (p' + 1)(2p' + 1)C_n^{p'} + \frac{1}{2} \sum_{k=1}^n v_{2k+2} C_{n-k}^{p'-k-1} - \sum_{k=1}^{n-1} C_k^1 C_{n-k}^{p'}, \quad 1 \leq p' \leq 2n, \\
C_0^0 &= 1, \quad C_n^{p'} = 0 \quad (n \geq 1, p' < 1).
\end{aligned} \tag{6.79}$$

After solving these recursion relations, the coefficients a_k in (6.71) are given by $a_k = (-1)^{k+1} C_{k,1}$. For brevity, we list here the first sixteen expansion coefficients for F , calculated with the help of MATHEMATICA or REDUCE programs:³

$$\begin{aligned}
a_0 &= \frac{1}{2}, \quad a_1 = \frac{1}{4}, \quad a_2 = \frac{1}{16}, \quad a_3 = 0, \quad a_4 = -\frac{1}{256}, \quad a_5 = 0, \\
a_6 &= \frac{1}{2048}, \quad a_7 = 0, \quad a_8 = -\frac{5}{65536}, \quad a_9 = 0, \\
a_{10} &= \frac{7}{524288}, \quad a_{11} = 0, \quad a_{12} = -\frac{21}{8388608}, \quad a_{13} = 0, \\
a_{14} &= \frac{33}{67108864}, \quad a_{15} = 0, \quad a_{16} = -\frac{429}{4294967296}, \dots \dots
\end{aligned} \tag{6.80}$$

6.4.3 Variational Strong-Coupling Approximations

We are now ready to calculate successive strong-coupling approximations to the function $F(g)$. It will be convenient to remove the expected correct d dependence π^2/d^2 from $F(g)$, and study the function $\tilde{F}(\bar{g}) \equiv F(g)/g$ which depends only on the dimensionless reduced coupling constant $\bar{g} = g/\omega$. The limit $\omega \rightarrow 0$ corresponds to a strong-coupling limit in the reduced coupling constant \bar{g} . According to the general theory of variational perturbation theory and its strong-coupling limit in Sections 5.14 and 5.17, the N th order approximation to the strong-coupling limit of $\tilde{F}(\bar{g})$, to be denoted by \tilde{F}^* , is found by replacing, in the series truncated after the

³The programs can be downloaded from www.physik.fu-berlin.de/~kleinert/b5/programs

N th term, $\tilde{F}_N(g/\omega)$, the frequency ω by the identical expression $\sqrt{\Omega^2 - gr^2/2M}$, where

$$r^2 \equiv 2M(\Omega^2 - \omega^2)/g. \tag{6.81}$$

For a moment, this is treated as an independent variable, whereas Ω is a dummy parameter. Then the square root is expanded binomially in powers of g , and $\tilde{F}_N(g/\sqrt{\Omega^2 - gr^2/2M})$ is re-expanded up to order g^N . After that, r is replaced by its proper value. In this way we obtain a function $\tilde{F}_N(g, \Omega)$ which depends on Ω , which thus becomes a variational parameter. The best approximation is obtained by extremizing $\tilde{F}_N(g, \Omega)$ with respect to ω . Setting $\omega = 0$, we go to the strong-coupling limit $g \rightarrow \infty$. There the optimal Ω grows proportionally to g , so that $g/\Omega = c^{-1}$ is finite, and the variational expression $\tilde{F}_N(g, \Omega)$ becomes a function of $f_N(c)$. In this limit, the above re-expansion amounts simply to replacing each power ω^n in each expansion terms of $\tilde{F}_N(\bar{g})$ by the binomial expansion of $(1 - 1)^{-n/2}$ truncated after the $(N - n)$ th term, and replacing \bar{g} by c^{-1} . The first nine variational functions $f_N(c)$ are listed in Table 6.1. The functions $f_N(c)$ are minimized starting from $f_2(c)$ and searching the minimum of each successive $f_3(c), f_3(c), \dots$ nearest to the previous one. The functions $f_N(c)$ together with their minima are plotted in Fig. 6.5. The minima lie at

Table 6.1 First eight variational functions $f_N(c)$.

$$\begin{aligned} f_2(c) &= \frac{1}{4} + \frac{1}{16c} + \frac{3c}{16} \\ f_3(c) &= \frac{1}{4} + \frac{3}{32c} + \frac{5c}{32} \\ f_4(c) &= \frac{1}{4} - \frac{1}{256c^3} + \frac{15}{128c} + \frac{35c}{256} \\ f_5(c) &= \frac{1}{4} - \frac{5}{512c^3} + \frac{35}{256c} + \frac{63c}{512} \\ f_6(c) &= \frac{1}{4} + \frac{1}{2048c^5} - \frac{35}{2048c^3} + \frac{315}{2048c} + \frac{231c}{2048} \\ f_7(c) &= \frac{1}{4} + \frac{7}{4096c^5} - \frac{105}{4096c^3} + \frac{693}{4096c} + \frac{429c}{4096} \\ f_8(c) &= \frac{1}{4} - \frac{5}{65536c^7} + \frac{63}{16384c^5} - \frac{1155}{32768c^3} + \frac{3003}{16384c} + \frac{6435c}{65536} \\ f_9(c) &= \frac{1}{4} - \frac{45}{131072c^7} + \frac{231}{32768c^5} - \frac{3003}{65536c^3} + \frac{6435}{32768c} + \frac{12155c}{131072} \end{aligned}$$

Figure 6.5 Variational functions $f_N(c)$ for particle between walls up to $N = 16$ are shown together with their minima whose y -coordinates approach rapidly the correct limiting value $1/2$.

$$\begin{aligned}
 (N, f_N^{\min}) = & (2, 0.466506), (3, 0.492061), (4, 0.497701), \\
 & (5, 0.499253), (6, 0.499738), (7, 0.499903), \\
 & (8, 0.499963), (9, 0.499985), (10, 0.499994), \\
 & (11, 0.499998), (12, 0.499999), (13, 0.5000), \\
 & (14, 0.50000), (15, 0.50000), (16, 0.5000). \tag{6.82}
 \end{aligned}$$

They converge exponentially fast against the known result 1/2, as shown in Fig. 6.6.

6.4.4 Special Properties of Expansion

The alert reader will have noted that the expansion coefficients (6.80) possess two special properties: First, they lack the factorial growth at large orders which would be found for a single power $[u^2(\tau)]^{k+1}$ of the interaction potential, as mentioned in Eq.(3C.27) and will be proved in Eq. (17.323). The factorial growth is canceled by the specific combination of the different powers in the interaction (6.72), making the series (6.71) convergent inside a certain circle. Still, since this circle has a finite radius (the ratio test shows that it is unity), this convergent series cannot be evaluated in the limit of large g which we want to do, so that variational strong-coupling theory is not superfluous. However, there is a second remarkable property of the coefficients (6.80): They contain an infinite number of zeros in the sequence of coefficients for each odd number, except for the first one. We may take advantage of this property by separating off the irregular term $a_1g = g/4 = \pi^2/4d^2$, setting $\alpha = g^2/4\omega^2$, and rewriting $\tilde{F}(\bar{g})$ as

$$\tilde{F}(\alpha) = \frac{1}{4} \left[1 + \frac{1}{\sqrt{\alpha}} h(\alpha) \right], \quad h(\alpha) \equiv \sum_{n=0}^N 2^{2n+1} a_{2n} \alpha^n. \tag{6.83}$$

Inserting the numbers (6.80), the expansion of $h(\alpha)$ reads

$$h(\alpha) = 1 + \frac{\alpha}{2} - \frac{\alpha^2}{8} + \frac{\alpha^3}{16} - \frac{5}{128} \alpha^4 + \frac{7}{256} \alpha^5 - \frac{21}{1024} \alpha^6 + \frac{33}{2048} \alpha^7 - \frac{429}{32768} \alpha^8 + \dots \tag{6.84}$$

We now realize that this is the binomial power series expansion of $\sqrt{1+\alpha}$. Substituting this into (6.83), we find the exact ground state energy for the Euclidean action (6.67)

$$E^{(0)} = \frac{\pi^2}{4d^2} \left(1 + \sqrt{1 + \frac{1}{\alpha}} \right) = \frac{\pi^2}{4d^2} \left(1 + \sqrt{1 + 4\omega^2 \frac{d^4}{\pi^4}} \right). \tag{6.85}$$

Figure 6.6 Exponentially fast convergence of strong-coupling approximations towards exact value.

Here we can go directly to the strong-coupling limit $\alpha \rightarrow \infty$ to recover the exact ground state energy $E^{(0)} = \pi^2/2d^2$.

The energy (6.85) can of course be obtained directly by solving the Schrödinger equation associated with the potential (6.72),

$$\frac{1}{2} \left\{ -\frac{\partial^2}{\partial x^2} + \left[\frac{\lambda(1-\lambda)}{\cos^2 x} - 1 \right] \right\} \psi(x) = \frac{d^2}{\pi^2} E \psi(x), \quad (6.86)$$

where we have replaced $u \rightarrow dx/\pi$ and set $\omega^2 d^4/\pi^4 \equiv \lambda(\lambda-1)$, so that

$$\lambda = \frac{1}{2} \left(1 + \sqrt{1 + 4\omega^2 \frac{d^4}{\pi^4}} \right). \quad (6.87)$$

Equation (6.86) is of the Pöschl-Teller type [see Subsection 14.4.5], and has the ground state wave function, to be derived in Eq. (14.141),

$$\psi_0(x) = \text{const} \times \cos^\lambda x, \quad (6.88)$$

with the eigenvalue $\pi^2 E^{(0)}/d^2 = (\lambda^2 - 1)/2$, which agrees of course with Eq. (6.85).

If we were to apply the variational procedure to the series $h(\alpha)/\sqrt{\alpha}$ in F of Eq. (6.85), by replacing the factor $1/\omega^{2n}$ contained in each power α^n by $\Omega = \sqrt{\Omega^2 - r\alpha}$ and re-expanding now in powers of α rather than g , we would find that all approximation $h_N(c)$ would possess a minimum with unit value, such that the corresponding extremal functions $f_N(c)$ yield the correct final energy in *each* order N .

6.4.5 Exponentially Fast Convergence

With the exact result being known, let us calculate the exponential approach of the variational approximations observed in Fig. (6.6). Let us write the exact energy (6.85) as

$$E^{(0)} = \frac{1}{4} (g + \sqrt{g^2 + 4\omega^2}). \quad (6.89)$$

After the replacement $\omega \rightarrow \sqrt{\Omega^2 - \rho g}$, this becomes

$$E^{(0)} = \frac{\Omega}{4} \left(\hat{g} + \sqrt{\hat{g}^2 - 4\rho\hat{g} + 4} \right), \quad (6.90)$$

where $\hat{g} \equiv g/\Omega^2$. The N th-order approximant $f_N(g)$ of $E^{(0)}$ is obtained by expanding (6.91) in powers of \hat{g} up to order N ,

$$f_N(g) = \Omega \sum_0^N h_k(\rho) \hat{g}^k, \quad (6.91)$$

and substituting ρ by $2Mr^2 = (1 - \hat{\omega}^2)/\hat{g}$ [compare (6.81)], with $\hat{\omega}^2 \equiv \omega^2/\Omega^2$. The resulting function of \hat{g} is then optimized.

It is straightforward to find an integral representation for $F_N(g)$. Setting $r\hat{g} \equiv z$, we have

$$F_N = \frac{1}{2\pi i} \oint_{C_0} \frac{dz}{z^{N+1}} \frac{1 - z^{N+1}}{1 - z} f(z), \quad (6.92)$$

where the contour C_0 refers to small circle around the origin and

$$\begin{aligned} F(z) &= \frac{\Omega}{4} \left(\frac{z}{r} + \sqrt{\frac{z^2}{r^2} - 4z + 4} \right) \\ &= \frac{1}{4r} \left(z + \sqrt{(z - z_1)(z - z_2)} \right), \end{aligned} \quad (6.93)$$

with branch points at $z_{1,2} = 2r^2 \left(1 \pm \sqrt{1 - 1/r^2}\right)$. For $z < 1$, we rewrite

$$\begin{aligned} 1 - z^{N+1} &= (1 - z)(1 + z + \dots + z^N) = (1 - z)(N + 1) \\ &- (1 - z)^2 [N + (N - 1)z + \dots + z^{N-1}] \end{aligned} \quad (6.94)$$

and estimate this for $z \approx 1$ as

$$1 - z^{N+1} = (1 - z)(N + 1) + \mathcal{O}(|1 - z|^2 N^2). \quad (6.95)$$

Dividing the approximant (6.92) by Ω , and indicating this by a hat, we use (6.94) to write \hat{F}_N as a sum over the discontinuities across the two branch cuts:

$$\begin{aligned} \hat{F}_N &= \frac{(N + 1)}{2\pi i} \oint_{C_0} \frac{dz \hat{F}(z)}{z^{N+1}} \hat{F}(z) = \frac{(N + 1)}{N!} \hat{F}^{(N)}(0) \\ &= (N + 1) \sum_{i=1}^2 \int_{z_i}^{\circ} \frac{dz}{z^{N+1}} \hat{F}(z). \end{aligned} \quad (6.96)$$

The integrals yield a constant plus a product

$$\Delta \hat{F}_N \approx \frac{(N + 1)(N - \frac{3}{2})!}{N!} \frac{1}{(r^2)^N} \frac{1}{(1 + r^2)^N}, \quad (6.97)$$

which for large N can be approximated using Stirling's formula (5.204) by

$$\Delta \hat{F}_N \approx \frac{A}{(r^2)^N \sqrt{N}} e^{-r^2 N}. \quad (6.98)$$

In the strong-coupling limit of interest here, $\hat{\omega}^2 = 0$, and $r = 1/\hat{g} = \Omega/g = c$. In Fig. 6.5 we see that the optimal c -values tend to unity for $N \rightarrow \infty$, so that $\Delta \hat{f}_N$ goes to zero like e^{-N} , as observed in Fig. 6.6.

Many Particle Orbits – Statistics and Second Quantization

Realistic physical systems usually contain groups of identical particles such as specific atoms or electrons. Focusing on a single group, we shall label their orbits by $\mathbf{x}^{(\nu)}(t)$ with $\nu = 1, 2, 3, \dots, N$. Their Hamiltonian is invariant under the group of all $N!$ permutations of the orbital indices ν . Their Schrödinger wave functions can then be classified according to the irreducible representations of the permutation group.

Not all possible representations occur in nature. In more than two space dimensions, there exists a *superselection rule*, whose origin is yet to be explained, which eliminates all complicated representations and allows only for the two simplest ones to be realized: those with complete symmetry and those with complete antisymmetry. Particles which appear always with symmetric wave functions are called *bosons*. They all carry an integer-valued spin. Particles with antisymmetric wave functions are called *fermions*¹ and carry a spin whose value is half-integer.

The symmetric and antisymmetric wave functions give rise to the characteristic statistical behavior of fermions and bosons. Electrons, for example, being spin-1/2 particles, appear only in antisymmetric wave functions. The antisymmetry is the origin of the famous *Pauli exclusion principle*, allowing only a single particle of a definite spin orientation in a quantum state, which is the principal reason for the existence of the *periodic system* of elements, and thus of matter in general. The atoms in a gas of helium, on the other hand, have zero spin and are described by symmetric wave functions. These can accommodate an infinite number of particles in a single quantum state giving rise to the famous phenomenon of Bose-Einstein condensation. This phenomenon is observable in its purest form in the absence of interactions, where at zero temperature all particles condense in the ground state. In interacting systems, Bose-Einstein statistics can lead to the stunning quantum state of superfluidity.

The particular association of symmetry and spin can be explained within relativistic quantum field theories in spaces with more than two dimensions where it is shown to be intimately linked with the *locality* and *causality* of the theory.

¹Had M. Born as editor of *Zeitschrift für Physik* not kept a paper by P. Jordan in his suitcase for half a year in 1925, they would be called *jordanons*. See the bibliographical notes by B. Schroer (hep-th/0303241).

In two dimensions there can be particles with an exceptional statistical behavior. Their properties will be discussed in Section 7.5. In Chapter 16, such particles will serve to explain the fractional quantum Hall effect.

The problem to be solved in this chapter is how to incorporate the statistical properties into a path integral description of the orbits of a many-particle system. Afterwards we describe the formalism of *second quantization* or *field quantization* in which the path integral of *many* identical particle orbits is abandoned in favor of a path integral over a *single fluctuating field* which is able to account for the statistical properties in a most natural way.

7.1 Ensembles of Bose and Fermi Particle Orbits

For bosons, the incorporation of the statistical properties into the orbital path integrals is quite easy. Consider, for the moment, distinguishable particles. Their many-particle time evolution amplitude is given by the path integral

$$(\mathbf{x}_b^{(1)}, \dots, \mathbf{x}_b^{(N)}; t_b | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; t_a) = \prod_{\nu=1}^N \left[\int \mathcal{D}^D x^{(\nu)} \right] e^{i\mathcal{A}^{(N)}/\hbar}, \quad (7.1)$$

with an action of the typical form

$$\mathcal{A}^{(N)} = \int_{t_a}^{t_b} dt \left\{ \sum_{\nu=1}^N \left[\frac{M^{(\nu)}}{2} \dot{\mathbf{x}}^{(\nu)2} - V(\mathbf{x}^{(\nu)}) \right] - \frac{1}{2} \sum_{\nu \neq \nu'=1}^N V_{\text{int}}(\mathbf{x}^{(\nu)} - \mathbf{x}^{(\nu')}) \right\}, \quad (7.2)$$

where $V(\mathbf{x}^{(\nu)})$ is some common background potential for all particles interacting via the pair potential $V_{\text{int}}(\mathbf{x}^{(\nu)} - \mathbf{x}^{(\nu')})$. We shall ignore interactions involving more than two particles at the same time, for simplicity.

If we want to apply the path integral (7.1) to indistinguishable particles of spin zero, we merely have to *add* to the sum over all paths $\mathbf{x}^{(\nu)}(t)$ running to the final positions $\mathbf{x}_b^{(\nu)}$ the sum of all paths running to the indistinguishable permuted final positions $\mathbf{x}_b^{(p(\nu))}$. The amplitude for n bosons reads therefore

$$(\mathbf{x}_b^{(1)}, \dots, \mathbf{x}_b^{(N)}; t_b | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; t_a) = \sum_{p(\nu)} (\mathbf{x}_b^{(p(1))}, \dots, \mathbf{x}_b^{(p(N))}; t_b | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; t_a), \quad (7.3)$$

where $p(\nu)$ denotes the $N!$ permutations of the indices ν . For bosons of higher spin, the same procedure applies to each subset of particles with equal spin orientation.

A similar discussion holds for fermions. Their Schrödinger wave function requires complete antisymmetrization in the final positions. Correspondingly, the amplitude (7.1) has to be summed over all permuted final positions $\mathbf{x}_b^{(p(\nu))}$, with an extra minus sign for each odd permutation $p(\nu)$. Thus, the path integral involves both *sums and differences* of paths. So far, the measure of path integration has always been a true *sum* over paths. For this reason it will be preferable to attribute the alternating sign to an interaction between the orbits, to be called a *statistics interaction*. This interaction will be derived in Section 7.4.

For the statistical mechanics of Bose- and Fermi systems consider the imaginary-time version of the amplitude (7.3):

$$(\mathbf{x}_b^{(1)}, \dots, \mathbf{x}_b^{(N)}; \hbar\beta | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; 0) = \sum_{p(\nu)} \epsilon_{p(\nu)} (\mathbf{x}_b^{(p(1))}, \dots, \mathbf{x}_b^{(p(N))}; \hbar\beta | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; 0), \quad (7.4)$$

where $\epsilon_{p(\nu)} = \pm 1$ is the parity of even and odd permutations $p(\nu)$, to be used for Bosons and Fermions, respectively. Its spatial trace integral yields the partition function of N -particle orbits:

$$Z^{(N)} = \frac{1}{N!} \int d^D x^{(1)} \dots d^D x^{(N)} (\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)}; \hbar\beta | \mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)}; 0). \quad (7.5)$$

A factor $1/N!$ accounts for the indistinguishability of the permuted final configurations.

For free particles, each term in the sum (7.4) factorizes:

$$(\mathbf{x}_b^{(p(1))}, \dots, \mathbf{x}_b^{(p(N))}; \hbar\beta | \mathbf{x}_a^{(1)}, \dots, \mathbf{x}_a^{(N)}; 0)_0 = (\mathbf{x}_b^{(p(1))} \hbar\beta | \mathbf{x}_a^{(1)} 0)_0 \dots (\mathbf{x}_b^{(p(N))} \hbar\beta | \mathbf{x}_a^{(N)} 0)_0, \quad (7.6)$$

where each factor has a path integral representation

$$(\mathbf{x}_b^{(p(\nu))} \hbar\beta | \mathbf{x}_a^{(\nu)} 0)_0 = \int_{\mathbf{x}^{(\nu)}(0)=\mathbf{x}_a^{(\nu)}}^{\mathbf{x}^{(\nu)}(\hbar\beta)=\mathbf{x}_b^{(p(\nu))}} \mathcal{D}^D x^{(\nu)} \exp \left[-\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \frac{M}{2} \dot{\mathbf{x}}^{(\nu)2}(\tau) \right], \quad (7.7)$$

which is solved by the imaginary-time version of (2.74):

$$(\mathbf{x}_b^{(p(\nu))} \hbar\beta | \mathbf{x}_a^{(\nu)} 0)_0 = \frac{1}{\sqrt{2\pi\hbar^2\beta/M}^D} \exp \left\{ -\frac{1}{\hbar} \frac{M}{2} \frac{[\mathbf{x}_b^{(p(\nu))} - \mathbf{x}_a^{(\nu)}]^2}{\hbar\beta} \right\}. \quad (7.8)$$

The partition function can therefore be rewritten in the form

$$Z_0^{(N)} = \frac{1}{\sqrt{2\pi\hbar^2\beta/M}^{ND}} \frac{1}{N!} \int d^D x^{(1)} \dots d^D x^{(N)} \sum_{p(\nu)} \epsilon_{p(\nu)} \prod_{\nu=1}^N \exp \left\{ -\frac{1}{\hbar} \frac{M}{2} \frac{[\mathbf{x}^{(p(\nu))} - \mathbf{x}^{(\nu)}]^2}{\hbar\beta} \right\}. \quad (7.9)$$

This is a product of Gaussian convolution integrals which can easily be performed as before when deriving the time evolution amplitude (2.76) for free particles with the help of Formula (2.75). Each convolution integral simply extends the temporal length in the fluctuation factor by $\hbar\beta$. Due to the indistinguishability of the particles, only a few paths will have their end points connected to their own initial points, i.e., they satisfy periodic boundary conditions in the interval $(0, \hbar\beta)$. The sum over permutations connects the final point of some paths to the initial point of a different path, as illustrated in Fig. 7.1. Such paths satisfy periodic boundary conditions on an interval $(0, w\hbar\beta)$, where w is some integer number. This is seen most clearly by drawing the paths in Fig. 7.1 in an extended zone scheme shown in Fig. 7.2, which

Figure 7.1 Paths summed in partition function (7.9). Due to indistinguishability of particles, final points of one path may connect to initial points of another.

Figure 7.2 Periodic representation of paths summed in partition function (7.9), once in extended zone scheme, and once on D -dimensional hypercylinder embedded in $D + 1$ dimensions. The paths are shown in Fig. 7.1. There is now only one closed path on the cylinder. In general there are various disconnected parts of closed paths.

is reminiscent of Fig. 6.1. The extended zone scheme can, moreover, be placed on a hypercylinder, illustrated in the right-hand part of Fig. 7.2. In this way, all paths decompose into mutually disconnected groups of closed paths winding around the cylinder, each with a different *winding number* w [1]. An example for a connected path which winds three times around the D -dimensional cylinder contributes to the partition function a factor [using Formula (2.75)]:

$$\begin{aligned} \Delta Z_0^{(N)3} &= \frac{1}{\sqrt{2\pi\hbar^2\beta/M}^{3D}} \int d^D x^{(1)} d^D x^{(2)} d^D x^{(3)} \exp \left\{ -\frac{1}{\hbar} \frac{M}{2} \frac{[\mathbf{x}^{(3)} - \mathbf{x}^{(2)}]^2}{\hbar\beta} \right\} \\ &\times \exp \left\{ -\frac{1}{\hbar} \frac{M}{2} \frac{[\mathbf{x}^{(2)} - \mathbf{x}^{(1)}]^2}{\hbar\beta} \right\} \exp \left\{ -\frac{1}{\hbar} \frac{M}{2} \frac{[\mathbf{x}^{(1)} - \mathbf{x}^{(3)}]^2}{\hbar\beta} \right\} = \frac{V_D}{\sqrt{2\pi\hbar^2 3\beta/M}^D}. \end{aligned} \quad (7.10)$$

For cycles of length w the contribution is

$$\Delta Z_0^{(N)w} = Z_0(w\beta), \quad (7.11)$$

where $Z_0(w\beta)$ is the partition function of a free particle in a D -dimensional volume V_D for an imaginary-time interval $w\hbar\beta$:

$$Z_0(w\beta) = \frac{V_D}{\sqrt{2\pi\hbar^2 w\beta/M}^D}. \quad (7.12)$$

In terms of the thermal deBroglie length $l_e(\hbar\beta) \equiv \sqrt{2\pi\hbar^2\beta/M}$ associated with the temperature $T = 1/k_B\beta$ [recall (2.353)], this can be written as

$$Z_0(w\beta) = \frac{V_D}{l_e^D(w\hbar\beta)}. \quad (7.13)$$

There is an additional factor $1/w$ in Eq. (7.11), since the number of connected windings of the total $w!$ closed paths is $(w-1)!$. In group theoretic language, it is the number of *cycles* of length w , usually denoted by $(1, 2, 3, \dots, w)$, plus the $(w-1)!$ permutations of the numbers $2, 3, \dots, w$. They are illustrated in Fig. 7.3 for $w = 2, 3, 4$. In a decomposition of all $N!$ permutations as products of cycles, the number of elements consisting of C_1, C_2, C_3, \dots cycles of length $1, 2, 3, \dots$ contains

$$M(C_1, C_2, \dots, C_N) = \frac{N!}{\prod_{w=1}^N C_w! w^{C_w}} \quad (7.14)$$

elements [2].

With the knowledge of these combinatorial factors we can immediately write down the canonical partition function (7.9) of N bosons or fermions as the sum of all orbits around the cylinder, decomposed into cycles:

$$Z_0^{(N)}(\beta) = \frac{1}{N!} \sum_{p(\nu)} \epsilon_{p(\nu)} M(C_1, \dots, C_N) \prod_{\substack{w=1 \\ N = \sum_w w C_w}}^N [Z_0(w\beta)]^{C_w}. \quad (7.15)$$

The sum can be reordered as follows:

$$Z_0^{(N)} = \frac{1}{N!} \sum_{\substack{C_1, \dots, C_N \\ N = \sum_w w C_w}} M(C_1, \dots, C_N) \epsilon_{w, C_1, \dots, C_N} \prod_{w=1}^N [Z_0(w\beta)]^{C_w}. \quad (7.16)$$

The parity $\epsilon_{w, C_1, \dots, C_N}$ of permutations is equal to $(\pm 1)^{\sum_w (w+1)C_w}$. Inserting (7.14), the sum (7.16) can further be regrouped to

$$\begin{aligned} Z_0^{(N)}(\beta) &= \sum_{\substack{C_1, \dots, C_N \\ N = \sum_w w C_w}} \frac{1}{\prod_{w=1}^N C_w! w^{C_w}} (\pm 1)^{\sum_w (w+1)C_w} \prod_{w=1}^N [Z_0(w\beta)]^{C_w} \\ &= \sum_{\substack{C_1, \dots, C_N \\ N = \sum_w w C_w}} \prod_{w=1}^N \frac{1}{C_w!} \left[(\pm 1)^{w-1} \frac{Z_0(w\beta)}{w} \right]^{C_w}. \end{aligned} \quad (7.17)$$

For $N = 0$, this formula yields the trivial partition function $Z_0^{(0)}(\beta) = 1$ of the no-particle state, the *vacuum*. For $N = 1$, i.e., a single particle, we find $Z_0^{(1)}(\beta) = Z_0(\beta)$.

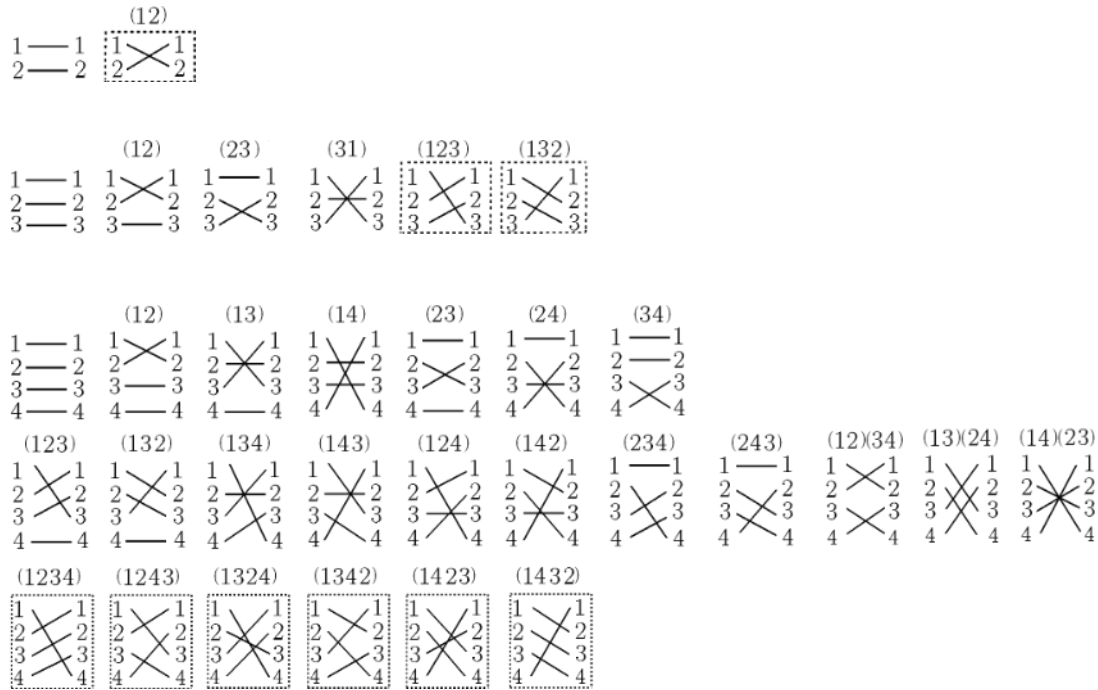

Figure 7.3 Among the $w!$ permutations of the different windings around the cylinder, $(w - 1)!$ are connected. They are marked by dotted frames. In the cycle notation for permutation group elements, these are (12) for two elements, (123), (132) for three elements, (1234), (1243), (1324), (1342), (1423), (1432) for four elements. The cycles are shown on top of each graph, with trivial cycles of unit length omitted. The graphs are ordered according to a decreasing number of cycles.

The higher $Z_0^{(N)}$ can be written down most efficiently if we introduce a characteristic temperature

$$T_c^{(0)} \equiv \frac{2\pi\hbar^2}{k_B M} \left[\frac{N}{V_D \zeta(D/2)} \right]^{2/D}, \tag{7.18}$$

and measure the temperature T in units of $T_c^{(0)}$, defining a reduced temperature $t \equiv T/T_c^{(0)}$. Then we can rewrite $Z_0^{(1)}(\beta)$ as $t^{D/2} V_D$. Introducing further the N -dependent variable

$$\tau_N \equiv \left[\frac{N}{\zeta(D/2)} \right]^{2/D} t, \tag{7.19}$$

we find $Z_0^{(1)} = \tau_1^{D/2}$. A few low- N examples are for bosons and fermions:

$$\begin{aligned} Z_0^{(2)} &= \pm 2^{-1-D/2} \tau_2^{D/2} + \tau_2^D, \\ Z_0^{(3)} &= \pm 3^{-1-D/2} \tau_3^{D/2} + 2^{-1-D/2} \tau_3^D \pm 3^{-1} 2^{-1} \tau_3^{3D/2}, \\ Z_0^{(4)} &= \pm 2^{-2-D} \tau_4^{D/2} + (2^{-3-D} + 3^{-1-D/2}) \tau_4^D \pm 2^{-2-\frac{D}{2}} \tau_4^{3D/2} + 3^{-1} 2^{-3} \tau_4^{2D}. \end{aligned} \tag{7.20}$$

From $Z_0^{(N)}(\beta)$ we calculate the specific heat [recall (2.602)] of the free canonical ensemble:

$$C_0^{(N)} = T \frac{d^2}{dT^2} [T \log Z_0^{(N)}] = \tau_N \frac{d^2}{d\tau_N^2} [\tau_N \log Z_0^{(N)}], \quad (7.21)$$

and plot it [3] in Fig. 7.4 against t for increasing particle number N . In the limit $N \rightarrow \infty$, the curves approach a limiting form with a phase transition at $T = T_c^{(0)}$, which will be derived from a grand-canonical ensemble in Eqs. (7.67) and (7.70).

The partition functions can most easily be calculated with the help of a recursion relation [4, 5], starting from $Z_0^{(0)} \equiv 1$:

$$Z_0^{(N)}(\beta) = \frac{1}{N} \sum_{n=1}^N (\pm 1)^{n-1} Z_0(n\beta) Z_0^{(N-n)}(\beta). \quad (7.22)$$

Figure 7.4 Plot of the specific heat of free Bose gas with $N = 10, 20, 50, 100, 500, \infty$ particles. The curve approaches for large T the Dulong-Petit limit $3k_B N/2$ corresponding to the three harmonic kinetic degrees of freedom in the classical Hamiltonian $\mathbf{p}^2/2M$. There are no harmonic potential degrees of freedom.

This relation is proved with the help of the grand-canonical partition function which is obtained by forming the sum over all canonical partition functions $Z_0^{(N)}(\beta)$ with a weight factor z^N :

$$Z_{G0}(\beta) \equiv \sum_{N=0}^{\infty} Z_0^{(N)}(\beta) z^N. \quad (7.23)$$

The parameter z is the Boltzmann factor of one particle with the chemical potential μ :

$$z = z(\beta) \equiv e^{\beta\mu}. \quad (7.24)$$

It is called the *fugacity* of the ensemble. Inserting the cycle decompositions (7.17), the sum becomes

$$Z_{G0}(\beta) = \sum_{\substack{C_1, \dots, C_N \\ N = \sum_w w C_w}} \prod_{w=1}^N \frac{1}{C_w!} \left[(\pm 1)^{w-1} \frac{Z_0(w\beta) e^{w\beta\mu}}{w} \right]^{C_w}. \quad (7.25)$$

The right-hand side may be rearranged to

$$\begin{aligned} Z_{G_0}(\beta) &= \prod_{w=1}^{\infty} \sum_{C_w=0}^{\infty} \frac{1}{C_w!} \left[(\pm 1)^{w-1} \frac{Z_0(w\beta) e^{w\beta\mu}}{w} \right]^{C_w} \\ &= \exp \left[\sum_{w=1}^{\infty} (\pm 1)^{w-1} \frac{Z_0(w\beta)}{w} e^{w\beta\mu} \right]. \end{aligned} \quad (7.26)$$

From this we read off the grand-canonical free energy [recall (1.545)] of noninteracting identical particles

$$F_G(\beta) \equiv -\frac{1}{\beta} \log Z_{G_0}(\beta) = -\frac{1}{\beta} \sum_{w=1}^{\infty} (\pm 1)^{w-1} \frac{Z_0(w\beta)}{w} e^{w\beta\mu}. \quad (7.27)$$

This is simply the sum of the contributions (7.11) of connected paths to the canonical partition function which wind $w = 1, 2, 3, \dots$ times around the cylinder [1, 6]. Thus we encounter the same situation as observed before in Section 3.20: the free energy of any quantum-mechanical system can be obtained from the perturbation expansion of the partition function by keeping only the connected diagrams.

The canonical partition function is obviously obtained from (7.27) by forming the derivative:

$$Z_0^{(N)}(\beta) = \frac{1}{N!} \frac{\partial^N}{\partial z^N} Z_{G_0}(\beta) \Big|_{z=0}. \quad (7.28)$$

It is now easy to derive the recursion relation (7.22). From the explicit form (7.27), we see that

$$\frac{\partial}{\partial z} Z_{G_0} = - \left(\frac{\partial}{\partial z} \beta F_G \right) Z_{G_0}. \quad (7.29)$$

Applying to this $N - 1$ more derivatives yields

$$\frac{\partial^{N-1}}{\partial z^{N-1}} \left[\frac{\partial}{\partial z} Z_{G_0} \right] = - \sum_{l=0}^{N-1} \frac{(N-1)!}{l!(N-l-1)!} \left(\frac{\partial^{l+1}}{\partial z^{l+1}} \beta F_G \right) \frac{\partial^{N-l-1}}{\partial z^{N-l-1}} Z_{G_0}.$$

To obtain from this $Z_0^{(N)}$ we must divide this equation by $N!$ and evaluate the derivatives at $z = 0$. From (7.27) we see that the $l + 1$ st derivative of the grand-canonical free energy is

$$\frac{\partial^{l+1}}{\partial z^{l+1}} \beta F_G \Big|_{z=0} = -(\pm 1)^l l! Z_0((l+1)\beta). \quad (7.30)$$

Thus we obtain

$$\frac{1}{N!} \frac{\partial^N}{\partial z^N} Z_{G_0} \Big|_{z=0} = \frac{1}{N} \sum_{l=0}^{N-1} (\pm 1)^l Z_0((l+1)\beta) \frac{1}{(N-l-1)!} \frac{\partial^{N-l-1}}{\partial z^{N-l-1}} Z_{G_0} \Big|_{z=0}.$$

Inserting here (7.28) and replacing $l \rightarrow n-1$ we obtain directly the recursion relation (7.22).

The grand-canonical free energy (7.27) may be simplified by using the property

$$Z_0(w\beta) = Z_0(\beta) \frac{1}{w^{D/2}} \quad (7.31)$$

of the free-particle partition function (7.12), to remove a factor $1/\sqrt{w^D}$ from $Z_0(w\beta)$. This brings (7.27) to the form

$$F_G = -\frac{1}{\beta} Z_0(\beta) \sum_{w=1}^{\infty} (\pm 1)^{w-1} \frac{e^{w\beta\mu}}{w^{D/2+1}}. \quad (7.32)$$

The average number of particles is found from the derivative with respect to the chemical potential²

$$N = -\frac{\partial}{\partial \mu} F_G = Z_0(\beta) \sum_{w=1}^{\infty} (\pm 1)^{w-1} \frac{e^{w\beta\mu}}{w^{D/2}}. \quad (7.33)$$

The sums over w converge certainly for negative or vanishing chemical potential μ , i.e., for fugacities smaller than unity. In Section 7.3 we shall see that for fermions, the convergence extends also to positive μ .

If the particles have a nonzero spin S , the above expressions carry a multiplicity factor $g_S = 2S + 1$, which has the value 2 for electrons.

The grand-canonical free energy (7.32) will now be studied in detail thereby revealing the interesting properties of many-boson and many-fermion orbits, the ability of the former to undergo *Bose-Einstein condensation*, and of the latter to form a *Fermi sphere* in momentum space.

7.2 Bose-Einstein Condensation

We shall now discuss the most interesting phenomenon observable in systems containing a large number of bosons, the Bose-Einstein condensation process.

7.2.1 Free Bose Gas

For bosons, the above thermodynamic functions (7.32) and (7.33) contain the functions

$$\zeta_\nu(z) \equiv \sum_{w=1}^{\infty} \frac{z^w}{w^\nu}. \quad (7.34)$$

These start out for small z like z , and increase for $z \rightarrow 1$ to $\zeta(\nu)$, where $\zeta(z)$ is Riemann's zeta function (2.521). The functions $\zeta_\nu(z)$ are called *Polylogarithmic functions* in the mathematical literature [7], where they are denoted by $\text{Li}_\nu(z)$.

²In grand-canonical ensembles, one always deals with the average particle number $\langle N \rangle$ for which one writes N in all thermodynamic equations [recall (1.551)]. This should be no lead to confusion.

They are related to the *Hurwitz zeta function* $\zeta(\nu, a, z) \equiv \sum_{w=0}^{\infty} z^w / (w+a)^\nu$ as $\zeta_\nu(z) = z\zeta(\nu, 1, z)$. The functions $\phi(z, \nu, a) = \zeta(\nu, a, z)$ are also known as *Lerch functions*.

In terms of the functions $\zeta_\nu(z)$, and the explicit form (7.12) of $Z_0(\beta)$, we may write F_G and N of Eqs. (7.32) and (7.33) simply as

$$F_G = -\frac{1}{\beta} Z_0(\beta) \zeta_{D/2+1}(z) = -\frac{1}{\beta} \frac{V_D}{l_e^D (\hbar\beta)} \zeta_{D/2+1}(z), \quad (7.35)$$

$$N = Z_0(\beta) \zeta_{D/2}(z) = \frac{V_D}{l_e^D (\hbar\beta)} \zeta_{D/2}(z). \quad (7.36)$$

The most interesting range where we want to know the functions $\zeta_\nu(z)$ is for negative small chemical potential μ . There the convergence is very slow and it is useful to find a faster-convergent representation. As in Subsection 2.15.6 we rewrite the sum over w for $z = e^{\beta\mu}$ as an integral plus a difference between sum and integral

$$\zeta_\nu(e^{\beta\mu}) \equiv \int_0^\infty dw \frac{e^{w\beta\mu}}{w^\nu} + \left(\sum_{w=1}^{\infty} - \int_0^\infty dw \right) \frac{e^{w\beta\mu}}{w^\nu}. \quad (7.37)$$

The integral yields $\Gamma(1-\nu)(-\beta\mu)^{\nu-1}$, and the remainder may be expanded sloppily in powers of μ to yield the Robinson expansion (2.581):

$$\zeta_\nu(e^{\beta\mu}) = \Gamma(1-\nu)(-\beta\mu)^{\nu-1} + \sum_{k=0}^{\infty} \frac{1}{k!} (\beta\mu)^k \zeta(\nu-k). \quad (7.38)$$

There exists a useful integral representation for the functions $\zeta_\nu(z)$:

$$\zeta_\nu(z) \equiv \frac{1}{\Gamma(\nu)} i_\nu(\beta\mu), \quad (7.39)$$

where $i_\nu(\alpha)$ denotes the integral

$$i_\nu(\alpha) \equiv \int_0^\infty d\varepsilon \frac{\varepsilon^{\nu-1}}{e^{\varepsilon-\alpha} - 1}, \quad (7.40)$$

containing the Bose distribution function (3.93):

$$n_\varepsilon^b = \frac{1}{e^{\varepsilon-\alpha} - 1}. \quad (7.41)$$

Indeed, by expanding the denominator in the integrand in a power series

$$\frac{1}{e^{\varepsilon-\alpha} - 1} = \sum_{w=1}^{\infty} e^{-w\varepsilon} e^{w\alpha}, \quad (7.42)$$

and performing the integrals over ε , we obtain directly the series (7.34).

It is instructive to express the grand-canonical free energy F_G in terms of the functions $i_\nu(\alpha)$. Combining Eqs. (7.35) with (7.39) and (7.40), we obtain

$$F_G = -\frac{1}{\beta} Z_0(\beta) \frac{i_{D/2+1}(\beta\mu)}{\Gamma(D/2+1)} = -\frac{1}{\beta\Gamma(D/2+1)} \frac{V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \frac{\varepsilon^{D/2}}{e^{\varepsilon-\beta\mu} - 1}. \quad (7.43)$$

The integral can be brought to another form by partial integration, using the fact that

$$\frac{1}{e^{\varepsilon-\beta\mu}-1} = \frac{\partial}{\partial\varepsilon} \log(1 - e^{-\varepsilon+\beta\mu}). \quad (7.44)$$

The boundary terms vanish, and we find immediately:

$$F_G = \frac{1}{\beta\Gamma(D/2)} \frac{V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \varepsilon^{D/2-1} \log(1 - e^{-\varepsilon+\beta\mu}). \quad (7.45)$$

This expression is obviously equal to the sum over momentum states of oscillators with energy $\hbar\omega_{\mathbf{p}} \equiv \mathbf{p}^2/2M$, evaluated in the thermodynamic limit $N \rightarrow \infty$ with fixed particle density N/V , where the momentum states become continuous:

$$F_G = \frac{1}{\beta} \sum_{\mathbf{p}} \log(1 - e^{-\beta\hbar\omega_{\mathbf{p}}+\beta\mu}). \quad (7.46)$$

This is easily verified if we rewrite the sum with the help of formula (1.558) for the surface of a unit sphere in D dimensions and a change of variables to the reduced particle energy $\varepsilon = \beta\mathbf{p}^2/2M$ as an integral

$$\begin{aligned} \sum_{\mathbf{p}} &\rightarrow V_D \int \frac{d^D p}{(2\pi\hbar)^D} = V_D S_D \frac{1}{(2\pi\hbar)^D} \int dp p^{D-1} = V_D S_D \frac{(2M/\beta)^{D/2}}{(2\pi\hbar)^D} \frac{1}{2} \int d\varepsilon \varepsilon^{D/2-1} \\ &= \frac{1}{\Gamma(D/2)} \frac{V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \varepsilon^{D/2-1}. \end{aligned} \quad (7.47)$$

Another way of expressing this limit is

$$\sum_{\mathbf{p}} \rightarrow \int_0^\infty d\varepsilon N_\varepsilon, \quad (7.48)$$

where N_ε is the reduced *density of states* per unit energy interval:

$$N_\varepsilon \equiv \frac{1}{\Gamma(D/2)} \frac{V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \varepsilon^{D/2-1}. \quad (7.49)$$

The free energy of each oscillator (7.46) differs from the usual harmonic oscillator expression (2.485) by a missing ground-state energy $\hbar\omega_{\mathbf{p}}/2$. The origin of this difference will be explained in Sections 7.7 and 7.14.

The particle number corresponding to the integral representations (7.45) and (7.46) is

$$N = -\frac{\partial}{\partial\mu} F_G = \frac{1}{\Gamma(D/2)} \frac{V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \frac{\varepsilon^{D/2-1}}{e^{\varepsilon-\beta\mu}-1} \approx \sum_{\mathbf{p}} \frac{1}{e^{\beta\hbar\omega_{\mathbf{p}}-\beta\mu}-1}. \quad (7.50)$$

Figure 7.5 Plot of functions $\zeta_\nu(z)$ for $\nu = 3/2$ and $5/2$ appearing in Bose-Einstein thermodynamics.

For a given particle number N , Eq. (7.36) allows us to calculate the fugacity as a function of the inverse temperature, $z(\beta)$, and from this the chemical potential $\mu(\beta) = \beta^{-1} \log z(\beta)$. This is most simply done by solving Eq. (7.36) for β as a function of z , and inverting the resulting function $\beta(z)$. The required functions $\zeta_\nu(z)$ are shown in Fig. 7.5.

There exists a solution $z(\beta)$ only if the total particle number N is smaller than the characteristic function defined by the right-hand side of (7.36) at unit fugacity $z(\beta) = 1$, or zero chemical potential $\mu = 0$:

$$N < \frac{V_D}{l_e^D(\hbar\beta)} \zeta(D/2). \quad (7.51)$$

Since $l_e(\hbar\beta)$ decreases with increasing temperature, this condition certainly holds at sufficiently high T . For decreasing temperature, the solution exists only as long as the temperature is higher than the critical temperature $T_c = 1/k_B\beta_c$, determined by

$$N = \frac{V_D}{l_e^D(\hbar\beta_c)} \zeta(D/2). \quad (7.52)$$

This determines the critical density of the atoms. The de Broglie length at the critical temperature will appear so frequently that we shall abbreviate it by ℓ_c :

$$l_e(\hbar\beta_c) = \ell_c \equiv \left[\frac{N}{V_D \zeta(D/2)} \right]^{-1/D}. \quad (7.53)$$

The critical density is reached at the characteristic temperature $T_c^{(0)}$ introduced in Eq. (7.18). Note that for a two-dimensional system, Eq. (7.18) yields $T_c^{(0)} = 0$, due to $\zeta(1) = \infty$, implying the nonexistence of a condensate. One can observe, however, definite experimental signals for the vicinity of a transition. In fact, we have neglected so far the interaction between the atoms, which is usually repulsive. This will give rise to a special type of phase transition called Kosterlitz-Thouless transition. For a discussion of this transition see other textbooks [8].

By combining (7.18) with (7.36) we obtain an equation for the temperature dependence of z above T_c :

$$1 = \left(\frac{T}{T_c}\right)^{D/2} \frac{\zeta_{D/2}(z(T))}{\zeta(D/2)}, \quad T > T_c. \quad (7.54)$$

This is solved most easily by calculating T/T_c as a function of $z = e^{\beta\mu}$. Since for small z , all functions $\eta_\nu(z)$ behave like z , the high-temperature-behavior of z is $z \approx \zeta(D/2)(T_c/T)^{D/2}$

If the temperature drops below T_c , the system can no longer accommodate all particles N in a normal state. A certain fraction of them, say $N_{\text{cond}}(T)$, is forced to condense in the ground state of zero momentum, forming the so-called *Bose-Einstein condensate*. The condensate acts like a particle reservoir with a chemical potential zero.

Both phases can be described by the single equation for the number of normal particles, i.e., those outside the condensate:

$$N_n(T) = \frac{V_D}{l_e^D (\hbar\beta)} \zeta_{D/2}(z(\beta)). \quad (7.55)$$

For $T > T_c$, all particles are normal and the relation between μ and the temperature is found from the equation $N_n(T) = N$, where (7.55) reduces to (7.36). For $T < T_c$, however, the chemical potential vanishes so that $z = 1$ and (7.55) reduces to

$$N_n(T) = \frac{V_D}{l_e^D (\hbar\beta)} \zeta_{D/2}(1), \quad (7.56)$$

which yields the temperature dependence of the number of normal particles:

$$\frac{N_n(T)}{N} = \left(\frac{T}{T_c}\right)^{D/2}, \quad T < T_c. \quad (7.57)$$

The density of particles in the condensate is therefore given by

$$\frac{N_{\text{cond}}(T)}{N} = 1 - \frac{N_n(T)}{N} = 1 - \left(\frac{T}{T_c}\right)^{D/2}. \quad (7.58)$$

We now calculate the internal energy which is, according to the general thermodynamic relation (1.553), given by

$$E = F_G + TS + \mu N = F_G - T\partial_T F_G + \mu N = \partial_\beta(\beta F_G) + \mu N. \quad (7.59)$$

Expressing N as $-\partial F_G/\partial\mu$, we can also write

$$E = F_G + (\beta\partial_\beta - \mu\partial_\mu)F_G. \quad (7.60)$$

Inserting (7.35) we see that only the β -derivative of the prefactor contributes since $(\beta\partial_\beta - \mu\partial_\mu)$ applied to any function of $z = e^{\beta\mu}$ vanishes. Thus we obtain directly

$$E = -\frac{D}{2}F_G, \quad (7.61)$$

which becomes with (7.35) and (7.36):

$$E = \frac{D}{2\beta} Z_0(\beta) \zeta_{D/2+1}(z) = \frac{D}{2} \frac{\zeta_{D/2+1}(z)}{\zeta_{D/2}(z)} N k_B T. \quad (7.62)$$

The entropy is found using the thermodynamic relation (1.574):

$$S = \frac{1}{T} (E - \mu N - F_G) = \frac{1}{T} \left(-\frac{D+2}{2} F_G - \mu N \right), \quad (7.63)$$

or, more explicitly,

$$S = k_B \left[\frac{D+2}{2} Z_0(\beta) \zeta_{D/2+1}(z) - \beta \mu N \right] = k_B N \left[\frac{D+2}{2} \frac{\zeta_{D/2+1}(z)}{\zeta_{D/2}(z)} - \beta \mu \right]. \quad (7.64)$$

For $T < T_c$, the entropy is given by (7.64) with $\mu = 0$, $z = 1$ and N replaced by the number N_n of normal particles of Eq. (7.57):

$$S_{<} = k_B N \left(\frac{T}{T_c} \right)^{D/2} \frac{(D+2)}{2} \frac{\zeta_{D/2+1}(1)}{\zeta_{D/2}(1)}, \quad T < T_c. \quad (7.65)$$

The particles in the condensate do not contribute since they are in a unique state. They do not contribute to E and F_G either since they have zero energy and $\mu = 0$. Similarly we find from (7.62):

$$E_{<} = \frac{D}{2} N k_B T \left(\frac{T}{T_c} \right)^{D/2} \frac{\zeta_{D/2+1}(1)}{\zeta_{D/2}(1)} = \frac{D}{D+2} T S_{<}, \quad T < T_c. \quad (7.66)$$

The specific heat C at a constant volume in units of k_B is found for $T < T_c$ from (7.65) via the relation $C = T \partial_T S|_N$ [recall (2.602)]:

$$C = k_B N \left(\frac{T}{T_c} \right)^{D/2} \frac{(D+2)D}{4} \frac{\zeta_{D/2+1}(1)}{\zeta_{D/2}(1)}, \quad T < T_c. \quad (7.67)$$

For $T > T_c$, the chemical potential at fixed N satisfies the equation

$$\beta \partial_\beta (\beta \mu) = \frac{D}{2} \frac{\zeta_{D/2}(z)}{\zeta_{D/2-1}(z)}. \quad (7.68)$$

This follows directly from the vanishing derivative $\beta \partial_\beta N = 0$ implied by the fixed particle number N . Applying the derivative to Eq. (7.36) and using the relation $z \partial_z \zeta_\nu(z) = \zeta_{\nu-1}(z)$, as well as $\beta \partial_\beta f(z) = z \partial_z f(z) \beta \partial_\beta (\beta \mu)$, we obtain

$$\begin{aligned} \beta \partial_\beta N &= [\beta \partial_\beta Z_0(\beta)] \zeta_{D/2}(z) + Z_0(\beta) \beta \partial_\beta \zeta_{D/2}(z) \\ &= -\frac{D}{2} Z_0(\beta) \zeta_{D/2}(z) + Z_0(\beta) \zeta_{D/2-1}(z) \beta \partial_\beta (\beta \mu) = 0, \end{aligned} \quad (7.69)$$

thus proving (7.68).

The specific heat C at a constant volume in units of k_B is found from the derivative $C = T\partial_T S|_N = -\beta^2\partial_\beta E|_N$, using once more (7.68):

$$C = k_B N \left[\frac{(D+2)D}{4} \frac{\zeta_{D/2+1}(z)}{\zeta_{D/2}(z)} - \frac{D^2}{4} \frac{\zeta_{D/2}(z)}{\zeta_{D/2-1}(z)} \right], \quad T > T_c. \quad (7.70)$$

At high temperatures, C tends to the Dulong-Petit limit $Dk_B N/2$ since for small z all $\zeta_\nu(z)$ behave like z .

Consider now the physical case $D = 3$, where the second denominator in (7.70) contains $\zeta_{1/2}(z)$. As the temperature approaches the critical point from above, z tends to unity from below and $\zeta_{1/2}(z)$ diverges. Thus $1/\zeta_{1/2}(1) = 0$ and the second term in (7.70) disappears, yielding a maximal value in three dimensions

$$C_{\max} = k_B N \frac{15}{4} \frac{\zeta_{5/2}(1)}{\zeta_{3/2}(1)} \approx k_B N 1.92567. \quad (7.71)$$

This value is the same as the critical value of Eq. (7.67) below T_c . The specific heat is therefore continuous at T_c . It shows, however, a marked kink. To calculate the jump in the slope we calculate the behavior of the thermodynamic quantities for $T \gtrsim T_c$. As T passes T_c from below, the chemical potential starts becoming smaller than zero, and we can expand Eq. (7.54)

$$1 = \left(\frac{T}{T_c} \right)^{3/2} \left[1 + \frac{\Delta\zeta_{3/2}(z)}{\zeta_{3/2}(1)} \right], \quad (7.72)$$

where the symbol Δ in front of a quantity indicates that the same quantity at zero chemical potential is subtracted. Near T_c , we can approximate

$$\left(\frac{T}{T_c} \right)^{3/2} - 1 \approx -\frac{\Delta\zeta_{3/2}(z)}{\zeta_{3/2}(1)}. \quad (7.73)$$

We now use the Robinson expansion (7.38) to approximate for small negative μ :

$$\zeta_{3/2}(e^{\beta\mu}) = \Gamma(-1/2)(-\beta\mu)^{1/2} + \zeta(3/2) + \beta\mu\zeta(1/2) + \dots, \quad (7.74)$$

with $\Gamma(-1/2) = -2\sqrt{\pi}$. The right-hand side of (7.73) becomes therefore $-\Delta\zeta_{3/2}(z)/\zeta_{3/2}(1) = -2\sqrt{\pi}/\zeta(3/2)(-\beta\mu)^{1/2}$. Inserting this into Eq. (7.73), we obtain the temperature dependence of $-\mu$ for $T \gtrsim T_c$:

$$-\mu \approx \frac{1}{4\pi} k_B T_c \zeta^2(3/2) \left[\left(\frac{T}{T_c} \right)^{3/2} - 1 \right]^2. \quad (7.75)$$

The leading square-root term on the right-hand side of (7.74) can also be derived from the integral representation (7.40) which receives for small α its main contribution from $\alpha \approx 0$, where $\Delta i_{3/2}(\alpha)$ can be approximated by

$$\Delta i_{3/2}(\alpha) = \int_0^\infty dz z^{1/2} \left(\frac{1}{e^{z-\alpha}-1} - \frac{1}{e^z-1} \right) \approx \alpha \int_0^\infty dz \frac{1}{z^{1/2}(z-\alpha)} = -\pi\sqrt{-\alpha}. \quad (7.76)$$

Using the relation (7.61) for $D = 3$, we calculate the derivative of the energy with respect to the chemical potential from

$$\left. \frac{\partial E}{\partial \mu} \right|_{T,V} = -\frac{3}{2} \left. \frac{\partial F_G}{\partial \mu} \right|_{T,V}. \quad (7.77)$$

This allows us to find the internal energy slightly above the critical temperature T_c , where $-\mu$ is small, as

$$E \approx E_{<} + \frac{3}{2} N \mu = E_{<} - \frac{3}{8\pi} N k_B T_c \zeta^2(3/2) \left[\left(\frac{T}{T_c} \right)^{3/2} - 1 \right]^2. \quad (7.78)$$

Forming the derivative of this with respect to the temperature we find that the slope of the specific heat below and above T_c jumps at T_c by

$$\Delta \left(\frac{\partial C}{\partial T} \right) \approx \frac{27}{16\pi} \zeta^2(3/2) N \frac{k_B}{T_c} \equiv 3.6658 N \frac{k_B}{T_c}, \quad (7.79)$$

the individual slopes being from (7.66) with $D = 3$ (using $\partial C / \partial T = \partial^2 E / \partial T^2$):

$$\left(\frac{\partial C_{<}}{\partial T} \right) = \frac{15}{4} \frac{3}{2} \frac{\zeta(5/2)}{\zeta(3/2)} \frac{N k_B}{T_c} \approx 2.8885 \frac{N k_B}{T_c}, \quad T < T_c, \quad (7.80)$$

and from (7.78):

$$\left(\frac{\partial C_{>}}{\partial T} \right) = \left(\frac{\partial C_{<}}{\partial T} \right) - \Delta \left(\frac{\partial C}{\partial T} \right) \approx -0.7715 \frac{N k_B}{T_c}, \quad T > T_c. \quad (7.81)$$

The specific heat of the three-dimensional Bose gas is plotted in Fig. 7.6, where it is compared with the specific heat of superfluid helium for the appropriate atomic parameters $n = 22.22 \text{ nm}^{-3}$, $M = 6.695 \times 10^{-27} \text{ kg}$, where the critical temperature is $T_c \approx 3.145 \text{ K}$, which is somewhat larger than $T_c \approx 2.17 \text{ K}$ of helium.

There are two major disagreements due to the strong interactions in helium. First, the small- T behavior is $(T/T_c)^{3/2}$ rather than the physical $(T/T_c)^3$ due to phonons. Second, the Dulong-Petit limit of an interacting system is closer to that of harmonic oscillators which is twice as big as the free-particle case. Recall that according to the Dulong-Petit law (2.603), C receives a contribution $N k_B T / 2$ per *harmonic* degree of freedom, potential as well as kinetic. Free particle energies are only harmonic in the momentum.

In 1995, Bose-Einstein condensation was observed in a dilute gas in a way that fits the above simple theoretical description [9]. When ^{87}Rb atoms were cooled down in a magnetic trap to temperatures less than 170 nK, about 50 000 atoms were observed to form a condensate, a kind of “superatom”. Recently, such condensates have been set into rotation and shown to become perforated by vortex lines [10] just like rotating superfluid helium II.

Figure 7.6 Specific heat of ideal Bose gas with phase transition at T_c . For comparison, we have also plotted the specific heat of superfluid helium for the same atomic parameters. The experimental curve is reduced by a factor 2 to have the same Dulong-Petit limit as free bosons.

7.2.2 Bose Gas in Finite Box

The condensation process can be understood better by studying a system in which there is a large but finite number of bosons enclosed in a large cubic box of size L . Then the sum on the right-hand side of Eq. (7.50) gives the contribution of the discrete momentum states to the total particle number. This implies that the function $\zeta_{D/2}(z)$ in Eq. (7.36) has to be replaced by a function $\zeta_{D/2}^{\text{box}}(z)$ defined by the sum over the discrete momentum vectors $\mathbf{p}_n = \hbar\pi(n_1, n_2, \dots, n_D)/L$ with $n_i = 1, 2, 3, \dots$:

$$N = \frac{V_D}{l_e^D(\hbar\beta)} \zeta_{D/2}^{\text{box}}(z) = \sum_{\mathbf{p}_n} \frac{1}{e^{\beta \mathbf{p}_n^2 / 2M - \beta\mu} - 1}. \quad (7.82)$$

This can be expressed in terms of the one-dimensional auxiliary partition function of a particle in a one-dimensional “box”:

$$Z_1(b) \equiv \sum_{n=1}^{\infty} e^{-bn^2/2}, \quad b \equiv \beta \hbar^2 \pi^2 / ML^2 = \pi l_e^2(\hbar\beta) / 2L^2, \quad (7.83)$$

as

$$N = \frac{V_D}{l_e^D(\hbar\beta)} \zeta_{D/2}^{\text{box}}(z) = \sum_w Z_1^D(wb) z^w. \quad (7.84)$$

The function $Z_1(b)$ is related to the *elliptic theta function*

$$\vartheta_3(u, z) \equiv 1 + 2 \sum_{n=1}^{\infty} z^{n^2} \cos 2nu \quad (7.85)$$

by $Z_1(b) = [\vartheta_3(0, e^{-b/2}) - 1]/2$. The small- b behavior of this function is easily calculated following the technique of Subsection 2.15.6. We rewrite the sum with the help of Poisson's summation formula (1.205) as a sum over integrals

$$\begin{aligned}\vartheta_3(0, e^{-b/2}) &= \sum_{k=-\infty}^{\infty} e^{-k^2 b/2} = \sum_{m=-\infty}^{\infty} \int_{-\infty}^{\infty} dk e^{-k^2 b/2 + 2\pi i k m} \\ &= \sqrt{\frac{2\pi}{b}} \left(1 + 2 \sum_{m=1}^{\infty} e^{-2\pi^2 m^2/b} \right).\end{aligned}\quad (7.86)$$

Thus, up to exponentially small corrections, we may replace $\vartheta_3(0, e^{-b/2})$ by $\sqrt{2\pi/b}$, so that for small b (i.e., large $L/\sqrt{\beta}$):

$$Z_1(b) = \sqrt{\frac{\pi}{2b}} - \frac{1}{2} + \mathcal{O}(e^{-2\pi^2/b}).\quad (7.87)$$

For large b , $Z_1(b)$ falls exponentially fast to zero.

In the sum (7.82), the lowest energy level with $\mathbf{p}_{1,\dots,1} = \hbar\pi(1, \dots, 1)/L$ plays a special role. Its contribution to the total particle number is the number of particles in the condensate:

$$N_{\text{cond}}(T) = \frac{1}{e^{Db/2 - \beta\mu} - 1} = \frac{z_D}{1 - z_D}, \quad z_D \equiv e^{\beta\mu - Db/2}.\quad (7.88)$$

This number diverges for $z_D \rightarrow 1$, where the box function $\zeta_{D/2}^{\text{box}}(z)$ has a pole $1/(Db/2 - \beta\mu)$. This pole prevents $\beta\mu$ from becoming exactly equal to $Db/2$ when solving the equation (7.82) for the particle number in the box.

For a large but finite system near $T = 0$, almost all particles will go into the condensate, so that $Db/2 - \beta\mu$ will be very small, of the order $1/N$, but not zero. The thermodynamic limit can be performed smoothly by defining a regularized function $\bar{\zeta}_{D/2}^{\text{box}}(z)$ in which the lowest, singular term in the sum (7.82) is omitted. Let us define the number of *normal* particles which have not condensed into the state of zero momentum as $N_n(T) = N - N_{\text{cond}}(T)$. Then we can rewrite Eq. (7.82) as an equation for the number of normal particles

$$N_n(T) = \frac{V_D}{l_e^D(\hbar\beta)} \bar{\zeta}_{D/2}^{\text{box}}(z(\beta)),\quad (7.89)$$

which reads more explicitly

$$N_n(T) = S_D(z_D) \equiv \sum_{w=1}^{\infty} [Z_1^D(wb) e^{wDb/2} - 1] z_D^w.\quad (7.90)$$

A would-be critical point may now be determined by setting here $z_D = 1$ and equating the resulting N_n with the total particle number N . If N is sufficiently large, we need only the small- b limit of $S_D(1)$ which is calculated in Appendix 7A

[see Eq. (7A.12)], so that the associated temperature $T_c^{(1)}$ is determined from the equation

$$N = \sqrt{\frac{\pi}{2b_c}}^3 \zeta(3/2) + \frac{3\pi}{4b_c^{(1)}} \log C_3 b_c + \dots, \quad (7.91)$$

where $C_3 \approx 0.0186$. In the thermodynamic limit, the critical temperature $T_c^{(0)}$ is obtained by ignoring the second term, yielding

$$N = \sqrt{\frac{\pi}{2b_c^{(0)}}}^3 \zeta(3/2), \quad (7.92)$$

in agreement with Eq. (7.52), if we recall b from (7.83). Using this we rewrite (7.91) as

$$1 \equiv \left(\frac{T_c^{(1)}}{T_c^{(0)}} \right)^{3/2} + \frac{3}{2N} \frac{\pi}{2b_c^{(0)}} \log C_3 b_c^{(0)}. \quad (7.93)$$

Expressing $b_c^{(0)}$ in terms of N from (7.92), this implies

$$\frac{\delta T_c^{(1)}}{T_c^{(0)}} \approx \frac{1}{\zeta^{2/3}(3/2) N^{1/3}} \log \frac{2}{\pi C_3} \frac{N^{2/3}}{\zeta^{2/3}(3/2)}. \quad (7.94)$$

Experimentally, the temperature $T_c^{(1)}$ is not immediately accessible. What is easy to find is the place where the condensate density has the largest curvature, i.e., where $d^3 N_{\text{cond}}/dT^3 = 0$. The associated temperature T_c^{exp} is larger than $T_c^{(1)}$ by a factor $1 + \mathcal{O}(1/N)$, so that it does not modify the leading finite-size correction to order in $1/N^{1/3}$. The proof is given in Appendix 7B.

7.2.3 Effect of Interactions

Superfluid helium has a lower transition temperature than the ideal Bose gas. This should be expected since the atomic repulsion impedes the condensation process of the atoms in the zero-momentum state. Indeed, a simple perturbative calculation based on a potential whose Fourier transform behaves for small momenta like

$$\tilde{V}(\mathbf{k}) = g \left[1 - r_{\text{eff}}^2 \mathbf{k}^2/6 + \dots \right] \quad (7.95)$$

gives a negative shift $\Delta T_c \equiv T_c - T_c^{(0)}$ proportional to the particle density [11]:

$$\frac{\Delta T_c}{T_c^{(0)}} = -\frac{1}{3\hbar^2} M r_{\text{eff}}^2 g \frac{N}{V}, \quad (7.96)$$

where V is the three-dimensional volume. When discussing the interacting system we shall refer to the previously calculated critical temperature of the free system as $T_c^{(0)}$. This result follows from the fact that for small g and r_{eff} , the free-particle energies $\epsilon_0(\mathbf{k}) = \hbar^2 \mathbf{k}^2/2M$ are changed to $\epsilon(\mathbf{k}) = \epsilon(0) + \hbar^2 \mathbf{k}^2/2M^*$ with a renormalized inverse effective mass $1/M^* = [1 - M r_{\text{eff}}^2 g N/3\hbar^2 V]/M$. Inserting this into Eq. (7.18), from

which we may extract the equation for the temperature shift $\Delta T_c/T_c^{(0)} = M/M^* - 1$, we obtain indeed the result (7.96). The parameter r_{eff} is called the *effective range* of the potential. The parameter g in (7.95) can be determined by measuring the s-wave *scattering length* a in a two-body scattering experiment. The relation is obtained from a solution of the Lippmann-Schwinger equation (1.525) for the T -matrix. In a dilute gas, this yields in three dimensions

$$g = \frac{2\pi\hbar^2}{M/2} a. \quad (7.97)$$

The denominator $M/2$ is the reduced mass of the two identical bosons. In $D = 2$ dimensions where g has the dimension energy \times length D , Eq. (7.97) is replaced by [12, 13, 14, 15, 17]

$$g = \frac{\pi^{D/2-1}}{2^{2-D}\Gamma(1-D/2)(na^D)^{D-2} + \Gamma(D/2-1)} \frac{2\pi\hbar^2}{M/2} a^{D-2} \equiv \gamma(D, na^D) \frac{2\pi\hbar^2}{M/2} a^{D-2}. \quad (7.98)$$

In the limit $D \rightarrow 2$, this becomes

$$g = -\frac{2\pi\hbar^2/M}{\ln(e\gamma na^2/2)}, \quad (7.99)$$

where γ is the Euler-Mascheroni constant. The logarithm in the denominator implies that the effective repulsion decreases only very slowly with decreasing density [16].

For a low particle density N/V , the effective range r_{eff} becomes irrelevant and the shift ΔT_c depends on the density with a lower power $(N/V)^{\kappa/3}$, $\kappa < 3$. The low-density limit can be treated by keeping in (7.95) only the first term corresponding to a pure δ -function repulsion

$$V(\mathbf{x} - \mathbf{x}') = g \delta^{(3)}(\mathbf{x} - \mathbf{x}'). \quad (7.100)$$

For this interaction, the lowest-order correction to the energy is in D dimensions

$$\Delta E = g \int d^D x n^2(\mathbf{x}), \quad (7.101)$$

where $n(\mathbf{x})$ is the local particle density. For a homogeneous gas, this changes the grand-canonical free energy from (7.35) to

$$F_G = -\frac{1}{\beta} \frac{V_D}{l_e^D(\hbar\beta)} \zeta_{D/2+1}(z) + g V_D \left[\frac{\zeta_{D/2}(z)}{l_e^D(\hbar\beta)} \right]^2 + \mathcal{O}(g^2), \quad (7.102)$$

where we have substituted $n(\mathbf{x})$ by the constant density N/V_D of Eq. (7.36). We now introduce a length parameter α proportional to the coupling constant g :

$$g \equiv \frac{2}{\beta} \frac{\alpha}{l_e(\hbar\beta)} l_e^D(\hbar\beta). \quad (7.103)$$

In three dimensions, α coincides in the dilute limit (small na^D) with the s-wave scattering length a of Eq. (7.97). In D dimensions, the relation is

$$\alpha = \gamma(D, na^D) \left[\frac{a}{l_e(\hbar\beta)} \right]^{D-3} a. \quad (7.104)$$

In two dimensions, this has the limit

$$\alpha = -\frac{l_e(\hbar\beta)}{\ln(e\gamma na^2/2)}. \quad (7.105)$$

We further introduce the reduced dimensionless coupling parameter $\hat{\alpha} \equiv \alpha/l_e(\hbar\beta) = \gamma(D, na^D) [a/l_e(\hbar\beta)]^{D-2}$, for brevity [recall (7.104)]. In terms of $\hat{\alpha}$, the grand-canonical free energy (7.102) takes the form

$$F_G = -\frac{1}{\beta} \frac{V_D}{l_e^D(\hbar\beta)} \left\{ \zeta_{D/2+1}(z) - 2\hat{\alpha} [\zeta_{D/2}(z)]^2 \right\} + \mathcal{O}(\alpha^2). \quad (7.106)$$

A second-order perturbation calculation extends this by a term [18, 19]

$$\Delta F_G = -\frac{1}{\beta} \frac{V_D}{l_e^D(\hbar\beta)} \left\{ 8\hat{\alpha}^2 h_D(z) \right\}, \quad (7.107)$$

where $h_D(z) = h_D^{(1)}(z) + h_D^{(2)}(z)$ is the sum of two terms. The first is simply

$$h_D^{(1)}(z) \equiv [\zeta_{D/2}(z)]^2 \zeta_{D/2-1}(z), \quad (7.108)$$

the second has been calculated only for $D = 3$:

$$h_3^{(2)}(z) \equiv \sum_{n_1, n_2, n_3=1}^{\infty} \frac{z^{n_1+n_2+n_3}}{\sqrt{n_1 n_2 n_3} (n_1+n_2)(n_1+n_3)}. \quad (7.109)$$

The associated particle number is

$$N = \frac{V_D}{l_e^D(\hbar\beta)} \left\{ \zeta_{D/2}(z) - 4\hat{\alpha} \zeta_{D/2-1}(z) \zeta_{D/2}(z) + 8\hat{\alpha}^2 z \frac{dh_D(z)}{dz} \right\} + \mathcal{O}(\alpha^3). \quad (7.110)$$

For small α , we may combine the equations for F_G and N and derive the following simple relation between the shift in the critical temperature and the change in the particle density caused by the interaction

$$\frac{\Delta T_c}{T_c^{(0)}} \approx -\frac{2}{D} \frac{\Delta n}{n}, \quad (7.111)$$

where Δn is the change in the density at the critical point caused by the interaction. The equation is correct to lowest order in the interaction strength.

The calculation of $\Delta T_c/T_c^{(0)}$ in three dimensions has turned out to be a difficult problem. The reason is that the perturbation series for the right-hand side of (7.111) is found to be an expansion in powers $(T - T_c^{(0)})^{-n}$ which needs a strong-coupling

evaluation for $T \rightarrow T_c^{(0)}$. Many theoretical papers have given completely different result, even in sign, and Monte Carlo data to indicate sign and order of magnitude. The ideal tool for such a calculation, field theoretic variational perturbation theory, has only recently been developed [20], and led to a result in rough agreement with Monte Carlo data [21]. Let us briefly review the history.

All theoretical results obtained in the literature have the generic form

$$\frac{\Delta T_c}{T_c^{(0)}} = c[\zeta(3/2)]^{\kappa/3} \left[\frac{a}{\ell_c} \right]^\kappa = c a^\kappa \left(\frac{N}{V} \right)^{\kappa/3}, \quad (7.112)$$

where the right-hand part of the equation follows from the middle part via Eq. (7.53). In an early calculation [22] based on the δ -function potential (7.100), κ was found to be $1/2$, with a downward shift of T_c . More recent studies, however, have led to the opposite sign [23]–[38]. The exponents κ found by different authors range from $\kappa = 1/2$ [23, 18, 31] to $\kappa = 3/2$ [19]. The most recent calculations yield $\kappa = 1$ [24]–[28], i.e., a direct proportionality of $\Delta T_c/T_c^{(0)}$ to the s-wave scattering length a , a result also found by Monte Carlo simulations [29, 30, 38], and by an extrapolation of experimental data measured in the strongly interacting superfluid ${}^4\text{He}$ after diluting it with the help of Vycor glass [40]. As far as the proportionality constant c is concerned, the literature offers various values which range for $\kappa = 1$ from $c = 0.34 \pm 0.03$ [29] to $c = 5.1$ [40]. A recent negative value $c \approx -0.93$ [41] has been shown to arise from a false assumption on the relation between canonical and grand-canonical partition function [42]. An older Monte Carlo result found $c \approx 2.3$ [30] lies close to the theoretical results of Refs. [23, 27, 28], who calculated $c_1 \approx -8\zeta(1/2)/3\zeta^{1/3}(3/2) \approx 2.83$, $8\pi/3\zeta^{4/3}(3/2) \approx 2.33$, 1.9 , respectively, while the extrapolation of the experimental data on ${}^4\text{He}$ in Vycor glass favored $c = 5.1$, near the theoretical estimate $c = 4.66$ of Stoof [24]. The latest Monte Carlo data, however, point towards a smaller value $c \approx 1.32 \pm 0.02$, close to theoretical numbers 1.48 and 1.14 in Refs. [35, 39] and 1.14 ± 0.11 in Ref. [21].

There is no space here to discuss in detail how the evaluation is done. We only want to point out an initially surprising result that in contrast to a potential with a finite effective range in (7.96), the δ -function repulsion (7.100) with a pure phase shift causes no change of T_c linear $an^{1/D}$ if only the first perturbative correction to the grand-canonical free energy in Eq. (7.106) is taken into account. A simple nonperturbative approach which shows this goes as follows: We observe that the one-loop expression for the free energy may be considered as the extremum with respect to σ of the variational expression

$$F_G^\sigma = -\frac{1}{\beta} \frac{V_D}{l_e^D(\hbar\beta)} \left[\zeta_{D/2+1}(ze^\sigma) - \frac{\sigma^2}{8\hat{\alpha}} \right], \quad (7.113)$$

which is certainly correct to first order in a . We have introduced the reduced dimensionless coupling parameter $\hat{\alpha} \equiv \alpha/l_e(\hbar\beta) = \gamma(D, na^D) [a/l_e(\hbar\beta)]^{D-2}$, for brevity [recall (7.104)]. The extremum lies at $\sigma = \Sigma$ which solves the implicit equation

$$\Sigma \equiv -4\hat{\alpha}\zeta_{D/2}(ze^\Sigma). \quad (7.114)$$

The extremal free energy is

$$F_G^\Sigma = -\frac{1}{\beta} \frac{V_D}{l_e^D(\hbar\beta)} \left\{ \zeta_{D/2+1}(Z) - 2\hat{\alpha}[\zeta_{D/2}(Z)]^2 \right\}, \quad Z \equiv ze^\Sigma. \quad (7.115)$$

The equation for the particle number, obtained from the derivative of the free energy (7.113) with respect to $-\mu$, reads

$$N = \frac{V_D}{l_e^D(\hbar\beta)} \zeta_{D/2}(Z), \quad (7.116)$$

and fixes Z . This equation has the same form as in the free case (7.36), so that the phase transition takes place at $Z = 1$, implying the same transition temperature as in the free system to this order. As discussed above, a nonzero shift (7.112) can only be found after summing up many higher-order Feynman diagrams which all diverge at the critical temperature.

Let us also point out that the path integral approach is not an adequate tool for discussing the condensed phase below the critical temperature, for which infinitely many particle orbits are needed. In the condensed phase, a quantum field theoretic formulation is more appropriate (see Section 7.6). The result of such a discussion is that due to the positive value of c in (7.112), the phase diagram has an unusual shape shown in Fig. 7.7. The nose in the phase transition curve implies that the system can undergo Bose-Einstein condensation slightly *above* $T_c^{(0)}$ if the interaction is *increased* (see Ref. [43]).

Figure 7.7 Reentrant transition in phase diagram of Bose-Einstein condensation for different interaction strengths. Curves were obtained in Ref. [43] from a variationally improved one-loop approximation to field-theoretic description with properly imposed positive slope at $T_c^{(0)}$ (dash length increasing with order of variational perturbation theory). Short solid curve and dashed straight line starting at $T_c^{(0)}$ are due to Ref. [38] and [21]. Diamonds correspond to the Monte-Carlo data of Ref. [29] and dots stem from Ref. [44], both scaled to their critical value $a_{\text{eff}}(T = 0) \approx 0.63$.

An important consequence of a repulsive short-range interaction is a change in the particle excitation energies below T_c . It was shown by Bogoliubov [46] that this changes the energy from the quadratic form $\epsilon(\mathbf{p}) = \mathbf{p}^2/2M$ to

$$\epsilon(\mathbf{p}) = \sqrt{\epsilon^2(\mathbf{p}) + 2gn\epsilon(\mathbf{p})}, \quad (7.117)$$

which starts linearly like $\epsilon(\mathbf{p}) = \sqrt{gn/M}|\mathbf{p}| = \hbar\sqrt{4\pi an/M}|\mathbf{p}|$ for small \mathbf{p} , the slope defining the second sound velocity. In the strongly interacting superfluid helium, the momentum dependence has the form shown in Fig. 7.8. It was shown by Bogoliubov

Figure 7.8 Energies of elementary excitations of superfluid ${}^4\text{He}$ measured by neutron scattering showing excitation energy of NG bosons [after R.A. Cowley and A.D. Woods, *Can. J. Phys* 49, 177 (1971)].

[46] that a system in which $\epsilon(\mathbf{p}) > v_c |\mathbf{p}|$ for some finite critical velocity v_c will display superfluidity as long as it moves with velocity $\mathbf{v} = \partial\epsilon(\mathbf{p})/\partial\mathbf{p}$ smaller than v_c . This follows by forming the free energy in a frame moving with velocity \mathbf{v} . It is given by the Legendre transform:

$$f \equiv \epsilon(\mathbf{p}) - \mathbf{v} \cdot \mathbf{p}, \quad (7.118)$$

which has a minimum at $\mathbf{p} = 0$ if as long as $|\mathbf{v}| < v_c$, implying that the particles do not move. Seen from the moving frame, they keep moving with a constant velocity $-\mathbf{v}$, without slowing down. This is in contrast to particles with the free spectrum $\epsilon(\mathbf{p}) = \mathbf{p}^2/2M$ for which f has a minimum at $\mathbf{p} = M\mathbf{v}$, implying that these particles always move with the same velocity as the moving frame. Note that the second sound waves of long wavelength have an energy $\epsilon(\mathbf{p} = c|\mathbf{p}|)$ just like light waves in the vacuum, with light velocity exchanged by the sound velocity. Even though the superfluid is nonrelativistic, the sound waves behave like relativistic particles. This phenomenon is known from the sound waves in crystals which behave similar to relativistic massless particles. In fact, the Debye theory of specific heat is very similar to Planck's black-body theory, except that the lattice size appears explicitly as a short-wavelength cutoff. It has recently been speculated that the relativistically invariant world we observe is merely the long-wavelength limit of a

world crystal whose lattice constant is very small [47], of the order of the Planck length $\ell_P \approx 8.08 \times 10^{-33}$ cm.

7.2.4 Bose-Einstein Condensation in Harmonic Trap

In a harmonic magnetic trap, the path integral (7.7) of the individual orbits becomes

$$(\mathbf{x}_b^{(p(\nu))} \hbar\beta | \mathbf{x}_a^{(\nu)} 0)_\omega = \int_{\mathbf{x}^{(\nu)}(\tau_a)=\mathbf{x}_a^{(\nu)}}^{\mathbf{x}^{(p(\nu))}(\tau_b)=\mathbf{x}_b^{(p(\nu))}} \mathcal{D}^D x^{(\nu)} \exp \left\{ -\frac{1}{\hbar} \int_0^{\hbar\beta} d\tau \frac{M}{2} [\dot{\mathbf{x}}^{(\nu)2} + \omega^2 \mathbf{x}^{(\nu)2}] \right\}, \quad (7.119)$$

and is solved by [recall (2.411)]

$$\begin{aligned} (\mathbf{x}_b^{(p(\nu))} \hbar\beta | \mathbf{x}_a^{(\nu)} 0)_\omega &= \frac{1}{\sqrt{2\pi\hbar/M}^D} \sqrt{\frac{\omega}{\sinh \beta\hbar\omega}}^D \\ &\times \exp \left\{ -\frac{1}{2\hbar} \frac{M\omega}{\sinh \beta\hbar\omega} [(\mathbf{x}_b^{(p(\nu))})^2 + \mathbf{x}_a^{(\nu)2}] \cosh \beta\hbar\omega - 2\mathbf{x}_b^{(p(\nu))} \mathbf{x}_a^{(\nu)} \right\}. \end{aligned} \quad (7.120)$$

The partition function (7.5) can therefore be rewritten in the form

$$\begin{aligned} Z_\omega^{(N)} &= \sqrt{\frac{M\omega}{2\pi\hbar \sinh \beta\hbar\omega}}^{ND} \frac{1}{N!} \int d^D x^{(1)} \dots d^D x^{(N)} \\ &\times \sum_{p(\nu)} \exp \left\{ -\frac{1}{2\hbar} \frac{M\omega}{\sinh \beta\hbar\omega} [(\mathbf{x}^{(p(\nu))})^2 + \mathbf{x}^{(\nu)2}] \cosh \beta\hbar\omega - 2\mathbf{x}^{(p(\nu))} \mathbf{x}^{(\nu)} \right\}. \end{aligned} \quad (7.121)$$

7.2.5 Thermodynamic Functions

With the same counting arguments as before we now obtain from the connected paths, which wind some number $w = 1, 2, 3, \dots$ times around the cylinder, a contribution to the partition function

$$\Delta Z_\omega^{(N)w} = Z_\omega(w\beta) \frac{1}{w} = \int d^D x z_\omega(w\beta; \mathbf{x}) \frac{1}{w}, \quad (7.122)$$

where

$$Z_\omega(\beta) = \frac{1}{[2 \sinh(\beta\hbar\omega/2)]^D} \quad (7.123)$$

is the D -dimensional harmonic partition function (2.407), and $z_\omega(w\beta; \mathbf{x})$ the associated density [compare (2.333) and (2.412)]:

$$z_\omega(\beta; \mathbf{x}) = \sqrt{\frac{\omega M}{2\pi\hbar \sinh \beta\hbar\omega}}^D \exp \left[-\frac{M\omega}{\hbar} \tanh \frac{\beta\hbar\omega}{2} \mathbf{x}^2 \right]. \quad (7.124)$$

Its spatial integral is the partition function of a free particle at an imaginary-time interval β [compare (2.412)]. The sum over all connected contributions (7.122) yields the grand-canonical free energy

$$F_G = -\frac{1}{\beta} \sum_{w=1}^{\infty} Z_\omega(w\beta) \frac{e^{w\beta\mu}}{w} = -\frac{1}{\beta} \sum_{w=1}^{\infty} \int d^D x z_\omega(w\beta; \mathbf{x}) \frac{e^{w\beta\mu}}{w}. \quad (7.125)$$

Note the important difference between this and the free-boson expression (7.27). Whereas in (7.27), the winding number appeared as a factor $w^{-D/2}$ which was removed from $Z_0(w\beta)$ by writing $Z_0(w\beta) = Z_0(\beta)/w^{D/2}$ which lead to (7.32), this is no longer possible here. The average number of particles is thus given by

$$N = -\frac{\partial}{\partial\mu}F_G = \sum_{w=1}^{\infty} Z_w(w\beta)e^{w\beta\mu} = \int d^Dx \sum_{w=1}^{\infty} z_w(w\beta; \mathbf{x})e^{w\beta\mu}. \quad (7.126)$$

Since $Z_w(w\beta) \approx e^{-wD\hbar\omega\beta/2}$ for large w , the sum over w converges only for $\mu < D\hbar\omega/2$. Introducing the fugacity associated with the ground-state energy

$$z_D(\beta) = e^{-(D\hbar\omega/2-\mu)\beta} = e^{-D\beta\hbar\omega/2}z, \quad (7.127)$$

by analogy with the fugacity (7.24) of the zero-momentum state, we may rewrite (7.126) as

$$N = -\frac{\partial}{\partial\mu}F_G = Z_w(\beta)\zeta_D(\beta\hbar\omega; z_D). \quad (7.128)$$

Here $\zeta_D(\beta\hbar\omega; z_D)$ are generalizations of the functions (7.34):

$$\zeta_D(\beta\hbar\omega; z_D) \equiv \sum_{w=1}^{\infty} \left[\frac{\sinh(\omega\hbar\beta/2)}{\sinh(w\omega\hbar\beta/2)} \right]^D e^{w\beta\mu} = Z_w^{-1}(\beta) \sum_{w=1}^{\infty} \frac{1}{(1 - e^{-2w\beta\hbar\omega})^{D/2}} z_D^w, \quad (7.129)$$

which reduce to $\zeta_D(z)$ in the trapless limit $\omega \rightarrow 0$, where $z_D \rightarrow z$. Expression (7.128) is the closest we can get to the free-boson formula (7.36).

We may define local versions of the functions $\zeta_D(\beta\hbar\omega; z_D)$ as in Eq.(7.124):

$$\zeta_D(\beta\hbar\omega; z_D; \mathbf{x}) \equiv Z_w^{-1}(\beta) \sum_{w=1}^{\infty} \frac{1}{(1 - e^{-2w\beta\hbar\omega})^{D/2}} \left(\frac{\omega M}{\pi\hbar} \right)^{D/2} e^{-M\omega \tanh(w\beta\hbar\omega/2)\mathbf{x}^2/\hbar} z_D^w, \quad (7.130)$$

in terms of which the particle number (7.128) reads

$$N = -\frac{\partial}{\partial\mu}F_G = \int d^Dx n_w(\mathbf{x}) \equiv Z_w(\beta) \int d^Dx \zeta_D(\beta\hbar\omega; z_D; \mathbf{x}), \quad (7.131)$$

and the free energy (7.125) becomes

$$F_G = \int d^Dx f(\mathbf{x}) \equiv -\frac{1}{\beta}Z_w(\beta) \int d^Dx \int_0^{z_D} \frac{dz}{z} \zeta_D(\beta\hbar\omega; z; \mathbf{x}). \quad (7.132)$$

For small trap frequency ω , the function (7.130) has a simple limiting form:

$$\zeta_D(\beta\hbar\omega; z_D; \mathbf{x}) \stackrel{\omega \approx 0}{\approx} \left(\frac{\beta\hbar\omega}{2\pi} \right)^{D/2} \frac{1}{\lambda_\omega^D} \sum_{w=1}^{\infty} \frac{1}{w^{D/2}} e^{-w\beta(M\omega^2\mathbf{x}^2/2-\mu)}, \quad (7.133)$$

where λ_ω is the oscillator length scale $\sqrt{\hbar/M\omega}$ of Eq. (2.303). Together with the prefactor $Z_w(\hbar\beta)$ in (7.131), which for small ω becomes $Z_w(\hbar\beta) \approx 1/(\beta\hbar\omega)^D$, this yields the particle density

$$n_0(\beta; z; \mathbf{x}) = \frac{1}{l_e^D(\hbar\beta)} \sum_{w=1}^{\infty} \frac{1}{w^{D/2}} e^{-w\beta[V(\mathbf{x})-\mu]} = \frac{1}{l_e^D(\hbar\beta)} \zeta_{D/2}(e^{-\beta[V(\mathbf{x})-\mu]}), \quad (7.134)$$

where $V(\mathbf{x}) = M\omega^2\mathbf{x}^2/2$ is the oscillator potential and $l_e(\hbar\beta)$ the thermal length scale (2.353). There is only one change with respect to the corresponding expression for the density in the homogeneous gas [compare (7.36)]: the fugacity $z = e^{\beta\mu}$ in the argument by the *local fugacity*

$$z(\mathbf{x}) \equiv e^{-\beta[V(\mathbf{x})-\mu]}. \quad (7.135)$$

The function $\zeta_D(\beta\hbar\omega; z_D)$ starts out like z_D , and diverges for $z_D \rightarrow 1$ like $[2 \sinh(\beta\hbar\omega/2)]^D/(z_D - 1)$. This divergence is the analog of the divergence of the box function (7.82) which reflects the formation of a condensate in the discrete ground state with particle number [compare (7.88)]

$$N_{\text{cond}} = \frac{1}{e^{D\beta\hbar\omega/2-\beta\mu} - 1}. \quad (7.136)$$

This number diverges for $\mu \rightarrow D\hbar\omega/2$ or $z_D \rightarrow 1$.

In a box with a finite the number of particles, Eq. (7.36) for the particle number was replaced by the equation for the normal particles (7.89) containing the regularized box functions $\bar{\zeta}_{D/2}^{\text{box}}(z)$. In the thermodynamic limit, this turned into the function $\zeta_{D/2}(z)$ in which the momentum sum was evaluated as an integral. The present functions $\zeta_D(\beta\hbar\omega; z_D)$ governing the particle number in the harmonic trap play precisely the role of the previous box functions, with a corresponding singular term which has to be subtracted, thus defining a regularized function

$$\bar{\zeta}_D(\beta\hbar\omega; z_D) \equiv \zeta_D(\beta\hbar\omega; z_D) - Z_\omega^{-1}(\beta) \frac{z_D}{1-z_D} = Z_\omega^{-1}(\beta) S_D(\beta\hbar\omega; z_D), \quad (7.137)$$

where $S(\beta\hbar\omega, z_D)$ is the sum

$$S(\beta\hbar\omega, z_D) \equiv \sum_{w=1}^{\infty} \left[\frac{1}{(1-e^{-w\beta\hbar\omega})^D} - 1 \right] z_D^w \quad (7.138)$$

The local function (7.130) has a corresponding divergence and can be regularized by a similar subtraction.

The sum (7.138) governs directly the number of *normal* particles

$$N_n(T) = Z_\omega(\beta) \bar{\zeta}_D(\beta\hbar\omega; z_D) \equiv S_D(\beta\hbar\omega, z_D). \quad (7.139)$$

The replacement of the singular equation (7.128) by the regular (7.139) of completely analogous to the replacement of the singular (7.82) by the regular (7.89) in the box.

7.2.6 Critical Temperature

Bose-Einstein condensation can be observed as a proper phase transition in the thermodynamic limit, in which N goes to infinity, at a constant average particle density in the trap defined by $N/\lambda_\omega^D \propto N\omega^D$. In this limit, ω goes to zero and the sum (7.139) becomes $\zeta_D(z_D)/\beta\hbar\omega^D$. The associated particle equation

$$N_n = \frac{1}{(\beta\hbar\omega)^D} \zeta_D(z_D) \quad (7.140)$$

can be solved only as long as $z_D < 1$. Above T_c , this equation determines z_D as a function of T from the condition that all particles are normal, $N_n = N$. Below T_c , it determines the temperature dependence of the number of normal particles by inserting $z_D = 1$, where

$$N_n = \frac{1}{(\beta\hbar\omega)^D} \zeta(D). \quad (7.141)$$

The particles in the ground state from a condensate, whose fraction is given by $N_{\text{cond}}(T)/N \equiv 1 - N_n(T)/N$. This is plotted in Fig. 7.9 as a function of the temperature for a total particle number $N = 40\,000$.

The critical point with $T = T_c$, $\mu = \mu_c = D\omega/2$ is reached if N_n is equal to the total particle number N where

$$k_B T_c^{(0)} = \hbar\omega \left[\frac{N}{\zeta(D)} \right]^{1/D}. \quad (7.142)$$

This formula has a solution only for $D > 1$.

Inserting (7.142) back into (7.162), we may re-express the normal fraction as a function of the temperature as follows:

$$\frac{N_n^{(0)}}{N} \approx \left(\frac{T}{T_c^{(0)}} \right)^D, \quad (7.143)$$

and the condensate fraction as

$$\frac{N_{\text{cond}}^{(0)}}{N} \approx 1 - \left(\frac{T}{T_c^{(0)}} \right)^D. \quad (7.144)$$

Including the next term in (7.162), the condensate fraction becomes

$$\frac{N_{\text{cond}}^{(0)}}{N} \approx 1 - \left(\frac{T}{T_c^{(0)} + \delta T_c} \right)^D. \quad (7.145)$$

It is interesting to re-express the critical temperature (7.142) in terms of the particle density at the origin which is at the critical point, according to Eq. (7.134),

$$n_0(\mathbf{0}) = \frac{1}{l_e^D (\hbar\beta_c)} \zeta(D/2), \quad (7.146)$$

where we have shortened the notation on an obvious way. From this we obtain

$$k_B T_c^{(0)} = \frac{2\pi\hbar^2}{M} \left[\frac{n_0(\mathbf{0})}{\zeta(D/2)} \right]^{2/D}. \quad (7.147)$$

Comparing this with the critical temperature *without a trap* in Eq. (7.18) we see that both expressions agree if we replace N/V by the uniform density $n_0(\mathbf{0})$. As an

Figure 7.9 Condensate fraction $N_{\text{cond}}/N \equiv 1 - N_{\text{n}}/N$ as function of temperature for total number of N particles. The long- and short-dashed curves on the left-hand show the zeroth and first-order approximations (7.144) and (7.163). The dotted curve displays the free-boson behavior (7.58). The right-hand figure shows experimental data for 40 000 ^{87}Rb atoms near T_c by Ensher *et. al.*, Phys. Rev. Lett. 77, 4984 (1996). The solid curve describes noninteracting Bose gas in a harmonic trap [cf. (7.144)]. The dotted curve corrects for finite- N effects [cf. (7.163)]. The dashed curve is the best fit to the data. The transition lies at $T_c \approx 280$ nK, about 3% below the dotted curve.

obvious generalization, we conclude that Bose condensation in *any* trap will set in when the density at the lowest point reaches the critical value determined by (7.147) [and (7.18)].

Note the different power D and argument in $\zeta(D)$ in Eq. (7.142) in comparison with the free-boson argument $D/2$ in Eq. (7.18). This has the consequence that in contrast to the free Bose gas, the gas in a trap can form a condensate in two dimensions. There is now, however, a problem in $D = 1$ dimension where (7.142) gives a vanishing transition temperature. The leading-order expression (7.142) for critical temperature can also be calculated from a simple statistical consideration. For small ω , the density of states available to the bosons is given by the classical expression (4.216):

$$\rho_{\text{cl}}(E) = \left(\frac{M}{2\pi\hbar^2} \right)^{D/2} \frac{1}{\Gamma(D/2)} \int d^D x [E - V(\mathbf{x})]^{D/2-1}. \quad (7.148)$$

The number of normal particles is given by the equation

$$N_{\text{n}} = \int_{E_{\text{min}}}^{\infty} dE \frac{\rho_{\text{cl}}(E)}{e^{E/k_B T} - 1}, \quad (7.149)$$

where E_{min} is the classical ground state energy. For a harmonic trap, the spatial integral in (7.148) can be done and is proportional to E^D , after which the integral over E in (7.149) yields $[k_B T/\hbar\omega]^D \zeta(D) = (T/T_c^{(0)})^D N$, in agreement with (7.143).

Alternatively we may use the phase space formula

$$\begin{aligned} N_n &= \int d^D x \frac{d^D p}{(2\pi\hbar)^D} \frac{1}{e^{\beta[p^2/2M+V(\mathbf{x})]} - 1} = \sum_{n=1}^{\infty} \int d^D x \frac{d^D p}{(2\pi\hbar)^D} e^{-n\beta[p^2/2M+V(\mathbf{x})]} \\ &= \sum_{n=1}^{\infty} \frac{1}{\sqrt{2\pi\hbar^2 n\beta/M}^D} \int d^D x e^{-n\beta V(\mathbf{x})}, \end{aligned} \quad (7.150)$$

where the spatial integration produces a factor $\sqrt{2\pi/M\omega^2 n\beta}$ so that the right-hand side becomes again $(T/T_c^{(0)})^D N$.

7.2.7 More General Anisotropic Trap

The equation (7.150) for the particle number can be easily calculated for a more general trap where the potential has the anisotropic power behavior

$$V(\mathbf{x}) = \frac{M}{2} \tilde{\omega}^2 \tilde{a}^2 \sum_{i=1}^D \left(\frac{|x_i|}{a_i} \right)^{p_i}, \quad (7.151)$$

where $\tilde{\omega}$ is some frequency parameter and \tilde{a} is the geometric average $\tilde{a} \equiv [\prod_{i=1}^D a_i]^{1/D}$. Inserting (7.151) into (7.150) we encounter a product of integrals

$$\prod_{i=1}^D \int_{-\infty}^{\infty} dx e^{-n\beta M \tilde{\omega}^2 \tilde{a}^2 (|x_i|/a_i)^{p_i}/2} = \prod_{i=1}^D \frac{a_i}{(\beta M \tilde{\omega}^2 \tilde{a}^2/2)^{1/p_i}} \Gamma(1 + 1/p_i), \quad (7.152)$$

so that the right-hand side of (7.150) becomes $(T/T_c^{(0)})^{\tilde{D}} N$, with the critical temperature

$$k_B T_c^{(0)} = \frac{M \tilde{\omega}^2 \tilde{a}^2}{2} \left(\frac{\hbar \tilde{\omega}}{M \tilde{\omega}^2 \tilde{a}^2} \right)^{D/\tilde{D}} \left[\frac{N \pi^{D/2}}{\zeta(\tilde{D}) \prod_{i=1}^D \Gamma(1 + 1/p_i)} \right]^{1/\tilde{D}}, \quad (7.153)$$

where \tilde{D} is the dimensionless parameter

$$\tilde{D} \equiv \frac{D}{2} + \sum_{i=1}^D \frac{1}{p_i}. \quad (7.154)$$

which takes over the role of D in the harmonic formula (7.142). A harmonic trap with different oscillator frequencies $\omega_1, \dots, \omega_D$ along the D Cartesian axes, is a special case of (7.151) with $p_i \equiv 2$, $\omega_i^2 = \tilde{\omega}^2 \tilde{a}^2/a_i^2$ and $\tilde{D} = D$, and formula (7.153) reduces to (7.142) with ω replaced by the geometric average of the frequencies $\tilde{\omega} \equiv (\omega_1 \cdots \omega_D)^{1/D}$. The parameter \tilde{a} disappears from the formula. A free Bose gas in a box of size $V_D = \prod_{i=1}^D (2a_i) = 2^D \tilde{a}^D$ is described by (7.151) in the limit $p_i \rightarrow \infty$ where $\tilde{D} = D/2$. Then Eq. (7.153) reduces to

$$k_B T_c^{(0)} = \frac{\pi \hbar^2}{2M \tilde{a}^2} \left[\frac{N}{\zeta(D/2)} \right]^{2/D} = \frac{2\pi \hbar^2}{M} \left[\frac{N}{V_D \zeta(D/2)} \right]^{2/D}, \quad (7.155)$$

in agreement with (7.53) and (7.18).

Another interesting limiting case is that of a box of length $L = 2a_1$ in the x -direction with $p_1 = \infty$, and two different oscillators of frequency ω_2 and ω_3 in the other two directions. To find $T_c^{(0)}$ for such a Bose gas we identify $\tilde{\omega}^2 \tilde{a}^2 / a_{2,3}^2 = \omega_{2,3}^2$ in the potential (7.151), so that $\tilde{\omega}^4 / \tilde{a}^2 = \omega_2^2 \omega_3^2 / a_1^2$, and obtain

$$k_B T_c^{(0)} = \hbar \tilde{\omega} \left(\frac{\pi \hbar}{2M\tilde{\omega}} \right)^{1/5} \left[\frac{N}{a_1 \zeta(5/2)} \right]^{2/5} = \hbar \tilde{\omega} \left(\frac{2\pi \lambda_{\omega_1} \lambda_{\omega_2}}{L^2} \right)^{1/5} \left[\frac{N}{\zeta(5/2)} \right]^{2/5}. \quad (7.156)$$

7.2.8 Rotating Bose-Einstein Gas

Another interesting potential can be prepared in the laboratory by rotating a Bose condensate [48] with an angular velocity Ω around the z -axis. The vertical trapping frequencies is $\omega_z \approx 2\pi \times 11.0 \text{ Hz} \approx 0.58 \times \text{nK}$, the horizontal one is $\omega_\perp \approx 6 \times \omega_z$. The centrifugal forces create an additional repulsive harmonic potential, bringing the rotating potential to the form

$$V(\mathbf{x}) = \frac{M\omega_z^2}{2} \left(z^2 + 36\eta r_\perp^2 + \frac{\kappa}{2} \frac{r_\perp^4}{\lambda_{\omega_z}^2} \right) = \frac{\hbar\omega_z}{2} \left(\frac{z^2}{\lambda_{\omega_z}^2} + 36\eta \frac{r_\perp^2}{\lambda_{\omega_z}^2} + \frac{\kappa}{2} \frac{r_\perp^4}{\lambda_{\omega_z}^4} \right), \quad (7.157)$$

where $r_\perp^2 = x^2 + y^2$, $\eta \equiv 1 - \Omega^2 / \omega_\perp^2$, $\kappa \approx 0.4$, and $\lambda_{\omega_z} \equiv 3.245 \mu\text{m} \approx 1.42 \times 10^{-3} \text{ K}$. For $\Omega > \omega_\perp$, η turns negative and the potential takes the form of a Mexican hat as shown in Fig. 3.13, with a circular minimum at $r_m^2 = -36\eta \lambda_{\omega_z}^2 / \kappa$. For large rotation speed, the potential may be approximated by a circular harmonic well, so that we may apply formula (7.156) with $a_1 = 2\pi r_m$, to obtain the η -independent critical temperature

$$k_B T_c^{(0)} \approx \hbar\omega_z \left(\frac{\kappa}{\pi} \right)^{1/5} \left[\frac{N}{\zeta(5/2)} \right]^{2/5}. \quad (7.158)$$

For $\kappa = 0.4$ and $N = 300\,000$, this yields $T_c \approx 53 \text{ nK}$.

At the critical rotation speed $\Omega = \omega_\perp$, the potential is purely quartic $r_\perp = \sqrt{(x^2 + y^2)}$. To estimate $T_c^{(0)}$ we approximate it for a moment by the slightly different potential (7.151) with the powers $p_1 = 2, p_2 = 4, p_3 = 4$, $a_1 = \lambda_{\omega_z}, a_2 = a_3 = \lambda_{\omega_z} (\kappa/2)^{1/4}$, so that formula (7.153) becomes

$$k_B T_c^{(0)} = \hbar\omega_z \left[\frac{\pi^2 \kappa}{16\Gamma^4(5/4)} \right]^{1/5} \left[\frac{N}{\zeta(5/2)} \right]^{2/5}. \quad (7.159)$$

It is easy to change this result so that it holds for the potential $\propto r^4 = (x + y)^4$ rather than $x^4 + y^4$: we multiply the right-hand side of equation (7.149) for N by a factor

$$\frac{2\pi \int r dr dx dy e^{-r^4}}{\int dx dy e^{-x^4 - y^4}} = \frac{\pi^{3/2}}{\Gamma[5/4]^2}. \quad (7.160)$$

This factor arrives inversely in front of N in Eq. (7.161), so that we obtain the critical temperature in the critically rotating Bose gas

$$k_B T_c^{(0)} = \hbar \omega_z \left(\frac{4\kappa}{\pi} \right)^{1/5} \left[\frac{N}{\zeta(5/2)} \right]^{2/5}. \quad (7.161)$$

The critical temperature at $\Omega = \omega_\perp$ is therefore by a factor $4^{1/5} \approx 1.32$ larger than at infinite Ω . Actually, this limit is somewhat academic in a semiclassical approximation since the quantum nature of the oscillator should be accounted for.

7.2.9 Finite-Size Corrections

Experiments never take place in the thermodynamic limit. The particle number is finite and for comparison with the data we must calculate finite-size corrections coming from finite N where $\omega \approx 1/N^{1/D}$ is small but nonzero. The transition is no longer sharp and the definition of the critical temperature is not precise. As in the thermodynamic limit, we shall identify it by the place where $z_D = 1$ in Eq. (7.139) for $N_n = N$. For $D > 3$, the corrections are obtained by expanding the first term in the sum (7.138) in powers of ω and performing the sums over w and subtracting $\zeta(0)$ for the sum $\sum_{w=1}^{\infty} 1$:

$$N_n(T_c) = \frac{1}{(\beta \hbar \omega)^D} \left[\zeta(D) + \frac{\beta \hbar \omega}{2} D \zeta(D-1) + \frac{(\omega \hbar \beta)^2}{24} D(3D-1) \zeta(D-2) + \dots \right] - \zeta(0). \quad (7.162)$$

The higher expansion terms contain logarithmically divergent expressions, for instance in one dimension the first term $\zeta(1)$, and in three dimensions $\zeta(D-2) = \zeta(1)$. These indicate that the expansion powers of $\beta \hbar \omega$ is has been done improperly at a singular point. Only the terms whose ζ -function have a positive argument can be trusted. A careful discussion along the lines of Subsection 2.15.6 reveals that $\zeta(1)$ must be replaced by $\zeta_{\text{reg}}(1) = -\log(\beta \hbar \omega) + \text{const.}$, similar to the replacement (2.590). The expansion is derived in Appendix 7A.

For $D > 1$, the expansion (7.162) can be used up to the $\zeta(D-1)$ terms and yields the finite-size correction to the number of normal particles

$$\frac{N_n}{N} = \left(\frac{T}{T_c^{(0)}} \right)^D + \frac{D}{2} \frac{\zeta(D-1)}{\zeta^{1-1/D}(D)} \frac{1}{N^{1/D}}. \quad (7.163)$$

Setting $N_n = N$, we obtain a shifted critical temperature by a relative amount

$$\frac{\delta T_c}{T_c^{(0)}} = -\frac{1}{2} \frac{\zeta(D-1)}{\zeta^{(D-1)/D}(D)} \frac{1}{N^{1/D}} + \dots \quad (7.164)$$

In three dimensions, the first correction shifts the critical temperature $T_c^{(0)}$ downwards by 2% for 40 000 atoms.

Note that correction (7.164) has no direct ω -dependence whose size enters only implicitly via $T_c^{(0)}$ of Eq. (7.142). In an anisotropic harmonic trap, the temperature

shift would carry a dimensionless factor $\tilde{\omega}/\bar{\omega}$ where $\bar{\omega}$ is the arithmetic mean $\bar{\omega} \equiv (\sum_{i=1}^D \omega_i)/D$.

The higher finite-size corrections for smaller particle numbers are all calculated in Appendix 7A. The result can quite simply be deduced by recalling that according to the Robinson expansion (2.583), the first term in the naive, wrong power series expansion of $\zeta_\nu(e^{-b}) = \sum_{w=1}^{\infty} e^{-wb}/w^\nu = \sum_{k=0}^{\infty} (-b)^k \zeta(\nu - k)/k!$ is corrected by changing the leading term $\zeta(\nu)$ to $\Gamma(1 - \nu)(-b)^{\nu-1} + \zeta(\nu)$ which remains finite for all positive integer ν . Hence we may expect that the correct equation for the critical temperature is obtained by performing this change in Eq. (7.162) on each $\zeta(\nu)$. This expectation is confirmed in Appendix 7A. It yields for $D = 3, 2, 1$ the equations for the number of particles in the excited states

$$N_n = \frac{1}{\beta\hbar\omega} \left[-(\log \beta\hbar\omega - \gamma) - \frac{\beta\hbar\omega}{2} \zeta(0) + \frac{(\beta\hbar\omega)^2}{12} \zeta(-1) + \dots \right], \quad (7.165)$$

$$N_n = \frac{1}{(\beta\hbar\omega)^2} \left[\zeta(2) - \beta\hbar\omega \left(\log \beta\hbar\omega - \gamma + \frac{1}{2} \right) - \frac{7(\beta\hbar\omega)^2}{12} \zeta(0) + \dots \right], \quad (7.166)$$

$$N_n = \frac{1}{(\beta\hbar\omega)^3} \left[\zeta(3) + \frac{3\beta\hbar\omega}{2} \zeta(2) - (\beta\hbar\omega)^2 \left(\log \beta\hbar\omega - \gamma + \frac{19}{24} \right) + \dots \right], \quad (7.167)$$

where $\gamma = 0.5772\dots$ is the Euler-Mascheroni number (2.469). Note that all nonlogarithmic expansion terms coincide with those of the naive expansion (7.162).

These equations may be solved for β at $N_n = N$ to obtain the critical temperature of the would-be phase transition.

Once we study the position of would-be transitions at finite size, it makes sense to include also the case $D = 1$ where the thermodynamic limit has no transition at all. There is a strong increase of number of particles in the ground state at a “critical temperature” determined by equating Eq. (7.165) with the total particle number N , which yields

$$k_B T_c^{(0)} = \hbar\omega N \frac{1}{(-\log \beta\hbar\omega + \gamma)} \approx \hbar\omega N \frac{1}{\log N}, \quad D = 1. \quad (7.168)$$

Note that this result can also be found also from the divergent naive expansion (7.162) by inserting for the divergent quantity $\zeta(1)$ the dimensionally regularized expression $\zeta_{\text{reg}}(1) = -\log(\beta\hbar\omega)$ of Eq. (2.590).

7.2.10 Entropy and Specific Heat

By comparing (7.126) with (7.125) we see that the grand-canonical free energy can be obtained from N_n of Eq. (7.162) by a simple multiplication with $-1/\beta$ and an increase of the arguments of the zeta-functions $\zeta(\nu)$ by one unit. Hence we have, up to first order corrections in ω

$$F_G(\beta, \mu_c) = -\frac{1}{\beta(\beta\hbar\omega)^D} \left[\zeta(D+1) + \beta\hbar\omega \frac{D}{2} \zeta(D) + \dots \right]. \quad (7.169)$$

From this we calculate immediately the entropy $S = -\partial_T F_G = k_B \beta^2 \partial_\beta F_G$ as

$$S = -k_B(D+1)\beta F_G = k_B(D+1) \frac{1}{(\beta\hbar\omega)^D} \left[\zeta(D+1) + \beta\hbar\omega \frac{D}{2} \zeta(D) + \dots \right]. \quad (7.170)$$

In terms of the lowest-order critical temperature (7.142), this becomes

$$S = k_B N(D+1) \left\{ \left(\frac{T}{T_c^{(0)}} \right)^D \frac{\zeta(D+1)}{\zeta(D)} + \frac{D}{2} \left[\frac{\zeta(D)}{N} \right]^{1/D} \left(\frac{T}{T_c^{(0)}} \right)^{D-1} + \dots \right\}. \quad (7.171)$$

From this we obtain the specific heat $C = T\partial_T S$ below T_c :

$$C = k_B N(D+1) \left\{ D \left(\frac{T}{T_c^{(0)}} \right)^D \frac{\zeta(D+1)}{\zeta(D)} + \frac{D(D-1)}{2} \left[\frac{\zeta(D)}{N} \right]^{1/D} \left(\frac{T}{T_c^{(0)}} \right)^{D-1} + \dots \right\}. \quad (7.172)$$

At the critical temperature, this has the maximal value

$$C_{\max} \approx k_B N(D+1) D \frac{\zeta(D+1)}{\zeta(D)} \left\{ 1 + \left[\frac{D-1}{2} \frac{\zeta^{1+1/D}(D)}{\zeta(D+1)} - \frac{D}{2} \frac{\zeta(D-1)}{\zeta^{1-1/D}(D)} \right] \frac{1}{N^{1/D}} \right\}. \quad (7.173)$$

In three dimensions, the lowest two approximations have their maximum at

$$C_{\max}^{(0)} \approx k_B N 10.805, \quad C_{\max}^{(1)} \approx k_B N 9.556. \quad (7.174)$$

Above T_c , we expand the total particle number (7.126) in powers of ω as in (7.162). The fugacity of the ground state is now different from unity:

$$N(\beta, \mu) = \frac{1}{(\beta\hbar\omega)^D} \left[\zeta_D(z_D) + \beta\hbar\omega \frac{D}{2} \zeta_{D-1}(z_D) + \dots \right]. \quad (7.175)$$

The grand-canonical free energy is

$$F_G(\beta, \mu) = -\frac{1}{\beta(\beta\hbar\omega)^D} \left[\zeta_{D+1}(z_D) + \beta\hbar\omega \frac{D}{2} \zeta_D(z_D) + \dots \right], \quad (7.176)$$

and the entropy

$$S(\beta, \mu) = k_B \frac{1}{(\beta\hbar\omega)^D} \left\{ (D+1) \zeta_{D+1}(z_D) + \frac{1}{2} (\beta\hbar\omega D^2 - 2\beta\mu) \zeta_D(z_D) + \dots \right\}. \quad (7.177)$$

The specific heat C is found from the derivative $-\beta\partial_\beta S|_N$ as

$$C(\beta, \mu) = k_B \frac{1}{(\beta\hbar\omega)^D} \left\{ (D+1) D \zeta_{D+1}(z_D) + \frac{1}{2} \left[D(D^2 + 1) \beta\hbar\omega - D\beta\mu - \beta\partial_\beta(\beta\mu) \right] \zeta_D(z_D) + \dots \right\}. \quad (7.178)$$

The derivative $\beta\partial_\beta(\beta\mu)$ is found as before from the condition: $\partial N(\beta, \mu(\beta))/\partial\beta = 0$, implying

$$0 = \frac{1}{(\beta\hbar\omega)^D} \left\{ - \left[D\zeta_D(z_D) + \beta\hbar\omega \frac{D}{2}(D-1)\zeta_{D-1}(z_D) \right] + \left[\zeta_{D-1}(z_D) + \beta\hbar\omega \frac{D}{2}\zeta_{D-2}(z_D) \right] \left[\beta\partial_\beta(\beta\mu) - \beta\hbar\omega \frac{D}{2} \right] + \dots \right\}, \quad (7.179)$$

so that we obtain

$$\beta\partial_\beta(\beta\mu) = D \frac{\zeta_D(z_D) + \beta\hbar\omega \frac{D}{2}\zeta_{D-2}(z_D) + \dots}{\zeta_{D-1}(z_D) + \beta\hbar\omega \frac{D}{2}\zeta_{D-2}(z_D) + \dots}. \quad (7.180)$$

Let us first consider the lowest approximation, where

$$N(\beta, \mu) \approx \frac{1}{(\beta\hbar\omega)^D} \zeta_D(z), \quad (7.181)$$

$$F_G(\beta, \mu) \approx -\frac{1}{\beta} \frac{1}{(\beta\hbar\omega)^D} \zeta_{D+1}(z) = -N \frac{1}{\beta} \frac{\zeta_{D+1}(z)}{\zeta_D(z)}, \quad (7.182)$$

$$S(\beta, \mu) \approx \frac{1}{T} \left[\frac{D+1}{\beta} \frac{1}{(\beta\hbar\omega)^D} \zeta_{D+1}(z) - \mu N \right] = Nk_B \left[\frac{D+1}{(\beta\hbar\omega)^D} \frac{\zeta_{D+1}(z)}{\zeta_D(z)} - \beta\mu \right], \quad (7.183)$$

so that from (7.60)

$$E(\beta, \mu) \approx \frac{D}{\beta} \frac{1}{(\beta\hbar\omega)^D} \zeta_{D+1}(z) = N \frac{D}{\beta} \frac{\zeta_{D+1}(z)}{\zeta_D(z)}. \quad (7.184)$$

The chemical potential at fixed N satisfies the equation

$$\beta\partial_\beta(\beta\mu) = D \frac{\zeta_D(z)}{\zeta_{D-1}(z)}. \quad (7.185)$$

The specific heat at a constant volume is

$$C = k_B N \left[(D+1)D \frac{\zeta_{D+1}(z)}{\zeta_D(z)} - D^2 \frac{\zeta_D(z)}{\zeta_{D-1}(z)} \right]. \quad (7.186)$$

At high temperatures, C tends to the Dulong-Petit limit DNk_B since for small z all $\zeta_\nu(z)$ behave like z . This is twice as big as the Dulong-Petit limit of the free Bose gas since there are twice as many harmonic modes.

As the temperature approaches the critical point from above, z tends to unity from below and we obtain a maximal value in three dimensions

$$C_{\max}^{(0)} = k_B N \left[12 \frac{\zeta_4(1)}{\zeta_3(1)} - 9 \frac{\zeta_3(1)}{\zeta_2(1)} \right] \approx k_B N 4.22785. \quad (7.187)$$

The specific heat for a fixed large number N of particles in a trap has a much sharper peak than for the free Bose gas. The two curves are compared in Fig. 7.10, where we also show how the peak is rounded for different finite numbers N .³

³P.W. Courteille, V.S. Bagnato, and V.I. Yukalov, *Laser Physics* 2, 659 (2001).

Figure 7.10 Peak of specific heat for infinite (left-hand plot) and various finite numbers 100, 1000, 10000 of particles N (right-hand plots) in harmonic trap. The large- N curve is compared with that of a free Bose gas.

7.2.11 Interactions in Harmonic Trap

Let us now study the effect of interactions on a Bose gas in an isotropic harmonic trap. This is most easily done by adding to the free part (7.132) the interaction (7.101) with $n(\mathbf{x})$ taken from (7.131), to express the grand-canonical free energy by analogy with (7.102) as

$$F_G = \int d^D x \left\{ -\frac{1}{\beta} Z_\omega(\beta) \int_0^{z_D} \frac{dz}{z} \zeta_D(\beta \hbar \omega; z; \mathbf{x}) + g [Z_\omega(\beta) \zeta_D(\beta \hbar \omega; z_D; \mathbf{x})]^2 \right\}. \quad (7.188)$$

Using the relation (7.103), this takes a form more similar to (7.106):

$$F_G = -\frac{1}{\beta} Z_\omega(\beta) \int d^D x \left\{ \int_0^{z_D} \frac{dz}{z} \zeta_D(\beta \hbar \omega; z; \mathbf{x}) - 2\hat{a} l_e^D(\hbar \beta) Z_\omega(\beta) [\zeta_D(\beta \hbar \omega; z_D; \mathbf{x})]^2 \right\}. \quad (7.189)$$

As in Eq. (7.113), we now construct the variational free energy to be extremized with respect to the local parameter $\sigma(\mathbf{x})$. Moreover, we shall find it convenient to express $\zeta(z)$ as $\int_0^z (dz'/z') \zeta(z')$. This leads to the variational expression

$$F_G^\sigma = -\frac{1}{\beta} Z_\omega(\beta) \int d^3 x \left[\int_0^{z_D e^{\sigma(\mathbf{x})}} \frac{dz}{z} \zeta_D(\beta \hbar \omega; z; \mathbf{x}) - \frac{\sigma^2(\mathbf{x})}{8\tilde{a}} \right], \quad (7.190)$$

where $z_D = e^{-(D\hbar\omega/2-\mu)\beta} = e^{-D\beta\hbar\omega/2}$ and

$$\tilde{a} \equiv \hat{a} l_e^D(\hbar \beta) Z_\omega(\beta) = \frac{a}{l_e(\hbar \beta)} l_e^D(\hbar \beta) Z_\omega(\beta). \quad (7.191)$$

The extremum lies at $\sigma(\mathbf{x}) = \Sigma(\mathbf{x})$ where by analogy with (7.114):

$$\Sigma(\mathbf{x}) \equiv -4\tilde{a} \zeta_D(\beta \hbar \omega; z_D e^{\Sigma(\mathbf{x})}; \mathbf{x}). \quad (7.192)$$

For a small trap frequency ω , we use the function $\zeta_D(\beta \hbar \omega; z_D; \mathbf{x})$ in the approximate form (7.133), written as

$$\zeta_D(\beta\hbar\omega; z_D; \mathbf{x}) \equiv \sum_{w=1}^{\infty} \sqrt{\frac{\omega^2 M \beta}{2\pi w}}^D z_D^w e^{-Mw\beta\omega^2 \mathbf{x}^2/2}. \quad (7.193)$$

In this approximation, Eq. (7.192) becomes

$$\Sigma(\mathbf{x}) \stackrel{\omega \approx 0}{\approx} -4\tilde{a} \sum_{w=1}^{\infty} \sqrt{\frac{\omega^2 M \beta}{2\pi w}}^D z_D^w e^{w\Sigma(\mathbf{x})} e^{-Mw\beta\omega^2 \mathbf{x}^2/2}. \quad (7.194)$$

For small \tilde{a} , $\Sigma(\mathbf{x})$ is also small, so that the factor $e^{w\Sigma(\mathbf{x})}$ on the right-hand side is close to unity and can be omitted. This will be inserted into the equation for the particle number above T_c :

$$N = \int d^D x n(\mathbf{x}) = Z_\omega(\beta) \int d^D x \bar{\zeta}_D(\beta\hbar\omega; z_D e^{\Sigma(\mathbf{x})}; \mathbf{x}). \quad (7.195)$$

Recall that in the thermodynamic limit for $D > 1$ where the phase transition properly exists, $\zeta_D(\beta\hbar\omega; z_D; \mathbf{x})$ and $\bar{\zeta}_D(\beta\hbar\omega; z_D; \mathbf{x})$ coincide, due to (7.139) and (7.141).

From (7.195) we may derive the following equation for the critical temperature as a function of z_D :

$$1 = \frac{Z_\omega(\beta)}{Z_\omega(\beta_c^{(0)})} \int d^D x \frac{\bar{\zeta}_D(\beta\hbar\omega; z_D e^{\Sigma(\mathbf{x})}; \mathbf{x})}{\bar{\zeta}_D(\beta_c^{(0)}\hbar\omega; 1)}, \quad (7.196)$$

where $T_c^{(0)}$ is the critical temperature in the trap *without* the repulsive interaction. The critical temperature T_c of the interacting system is reached if the second argument of $\bar{\zeta}_D(\beta\hbar\omega; z_D e^{\Sigma(\mathbf{x})}; \mathbf{x})$ hits the boundary of the unit convergence radius of the expansion (7.130) for $\mathbf{x} = 0$, i.e., if $z_D e^{\Sigma(\mathbf{0})} = 1$. Thus we find the equation for T_c :

$$1 = \frac{Z_\omega(\beta_c)}{Z_\omega(\beta_c^{(0)})} \int d^D x \frac{\bar{\zeta}_D(\beta_c\hbar\omega; e^{\Sigma_c(\mathbf{x}) - \Sigma_c(\mathbf{0})}; \mathbf{x})}{\bar{\zeta}_D(\beta_c^{(0)}\hbar\omega; 1)}, \quad (7.197)$$

where the subscript of $\Sigma_c(\mathbf{x})$ indicates that β in (7.194) has been set equal to β_c . In particular, \tilde{a} contained in $\Sigma_c(\mathbf{x})$ is equal to $\tilde{a}_c \equiv a/\ell_c$. Since this is small by assumption, we expand the numerator of (7.197) as

$$1 \approx \frac{Z_\omega(\beta_c)}{Z_\omega(\beta_c^{(0)})} \left\{ 1 + \frac{1}{\bar{\zeta}_D(\beta_c^{(0)}\hbar\omega; 1)} \int d^D x \Delta \bar{\zeta}_D(\beta_c^{(0)}\hbar\omega; 1; \mathbf{x}) \right\}, \quad (7.198)$$

where the integral has the explicit small- ω form

$$\int d^D x \sum_{w=1}^{\infty} \sqrt{\frac{\omega^2 M \beta_c^{(0)}}{2\pi w}}^D e^{-Mw\beta_c^{(0)}\omega^2 \mathbf{x}^2/2} \left(e^{w[\Sigma_c(\mathbf{x}) - \Sigma_c(\mathbf{0})]} - 1 \right). \quad (7.199)$$

In the subtracted term we have used the fact that for small ω , $\bar{\zeta}_D(\beta_c^{(0)}\hbar\omega; 1) \approx \bar{\zeta}_D(\beta_c\hbar\omega; 1) \approx \zeta(D)$ is independent of β [see (7.139) and (7.141)].

Next we approximate near $T_c^{(0)}$:

$$\frac{Z_\omega(\beta_c)}{Z_\omega(\beta_c^{(0)})} \equiv 1 + D \frac{\Delta T_c}{T_c^{(0)}} \frac{\beta_c^{(0)} \hbar \omega / 2}{\tanh(\beta_c^{(0)} \hbar \omega / 2)} \stackrel{\omega \approx 0}{\approx} 1 + D \frac{\Delta T_c}{T_c^{(0)}}, \quad (7.200)$$

such that Eq. (7.198) can be solved for $\Delta T_c / T_c^{(0)}$:

$$\frac{\Delta T_c}{T_c^{(0)}} \approx -\frac{1}{D} \frac{1}{\zeta(D)} \int d^D x \Delta \bar{\zeta}_D(\beta_c^{(0)} \hbar \omega; 1; \mathbf{x}). \quad (7.201)$$

On the right-hand side, we now insert (7.199) with the small quantity $\Sigma_c(\mathbf{x})$ approximated by Eq. (7.194) at $\beta_c^{(0)}$, in which the factor $e^{w\Sigma_c(\mathbf{x})}$ on the right-hand side is replaced by 1, and find for the integral (7.199):

$$-4\tilde{a}_c \int d^D x \sum_{w=1}^{\infty} \sqrt{\frac{\omega^2 M \beta_c^{(0)}}{2\pi w}} e^{-Mw\beta_c^{(0)}\omega^2 \mathbf{x}^2/2} w \sum_{w'=1}^{\infty} \sqrt{\frac{\omega^2 M \beta_c^{(0)}}{2\pi w'}} \left(e^{Mw'\beta_c^{(0)}\omega^2 \mathbf{x}^2/2} - 1 \right).$$

The integral leads to

$$-4\tilde{a}_c \sqrt{\frac{\omega^2 M \beta_c^{(0)}}{2\pi}} \sum_{w,w'=1}^{\infty} \frac{1}{w^{D/2-1} w'^{D/2}} \left[\frac{1}{(w+w')^{D/2}} - \frac{1}{w^{D/2}} \right] \equiv -4\hat{a}_c S(D), \quad (7.202)$$

where $S(D)$ abbreviates the double sum, whose prefactor has been simplified to $-4\hat{a}_c$ using (7.191) and the fact that for small ω , $Z_\omega(\beta_c^{(0)}) \approx (\omega \hbar \beta_c^{(0)})^{-D}$. For $D = 3$, the double sum has the value $S(3) \approx 1.2076 - \zeta(2)\zeta(3/2) \approx -3.089$. Inserting everything into (7.201), we obtain for small a and small ω the shift in the critical temperature

$$\frac{\Delta T_c}{T_c^{(0)}} \approx \frac{4\hat{a}_c S(D)}{D \zeta(D)} \stackrel{D=3}{\approx} -3.427 \frac{a}{\ell_c}. \quad (7.203)$$

In contrast to the free Bose gas, where a small δ -function repulsion does not produce any shift using the same approximation as here [recall (7.116)], and only a high-loop calculation leads to an upwards shift proportional to a , the critical temperature of the trapped Bose gas is shifted *downwards*. We can express ℓ_c in terms of the length scale $\lambda_\omega \equiv \sqrt{\hbar/M\omega}$ associated with the harmonic oscillator [recall Eq. (2.303)] and rewrite $\ell_c = \lambda_\omega \sqrt{2\pi\beta_c \hbar \omega}$. Together with the relation (7.142), we find

$$\frac{\Delta T_c}{T_c^{(0)}} \approx -3.427 \frac{1}{\sqrt{2\pi}[\zeta(3)]^{1/6}} \frac{a}{\lambda_\omega} N^{1/6} \approx -1.326 \frac{a}{\lambda_\omega} N^{1/6}. \quad (7.204)$$

Note that since ω is small, the temperature shift formula (7.201) can also be expressed in terms of the zero- ω density (7.134) as

$$\Delta T_c \stackrel{\omega, \tilde{a} \approx 0}{\approx} 2g \frac{\int d^3 x [\partial_\mu n_0(\mathbf{x})] [n_0(\mathbf{x}) - n_0(\mathbf{0})]}{\int d^3 x \partial_T n_0(\mathbf{x})}, \quad (7.205)$$

where we have omitted the other arguments β and z of $n_0(\beta; z; \mathbf{x})$, for brevity. To derive this formula we rewrite the grand-canonical free energy (7.190) as

$$F_G = -\frac{1}{\beta} \int d^3x \left[\int_0^{ze^{\beta\nu(\mathbf{x})}} \frac{dz'}{z'} n_0(\beta; z'; \mathbf{x}) - \beta \frac{\nu^2(\mathbf{x})}{4g} \right], \quad (7.206)$$

so that the particle number equation Eq. (7.195) takes the form

$$N = \int d^3x n_0(\beta; ze^{\beta\nu(\mathbf{x})}; \mathbf{x}). \quad (7.207)$$

Extremizing F_G in $\nu(\mathbf{x})$ yields the self-consistent equation

$$\nu(\mathbf{x}) = -2gn_0(\beta; ze^{\beta\nu(\mathbf{x})}; \mathbf{x}). \quad (7.208)$$

As before, the critical temperature is reached for $ze^{\beta\nu(\mathbf{0})} = 1$, implying that

$$N = \int d^3x n_0(\beta_c; ze^{-2\beta g[n_0(\mathbf{x}) - n_0(\mathbf{0})]}; \mathbf{x}). \quad (7.209)$$

In the exponent we have omitted again the arguments β and z of $n_0(\beta; z; \mathbf{x})$. If we now impose the condition of constant N , $\Delta N = (\Delta T_c \partial_T + \Delta \mu \partial_\mu) N = 0$, and insert $\Delta \mu = -2g[n_0(\mathbf{x}) - n_0(\mathbf{0})]$, we find (7.205). Inserting into (7.205) the density (7.134) for the general trap (7.151), we find the generalization of (7.203):

$$\frac{\Delta T_c}{T_c^{(0)}} \approx \frac{4\hat{a}_c}{\tilde{D}} \frac{1}{\zeta(\tilde{D})} \sum_{w, w'=1}^{\infty} \frac{1}{w^{D/2-1} w'^{D/2}} \left[\frac{1}{(w+w')^{\tilde{D}-D/2}} - \frac{1}{w^{\tilde{D}-D/2}} \right], \quad (7.210)$$

which vanishes for the homogeneous gas, as concluded before on the basis of Eq. (7.116).

Let us compare the result (7.204) with the experimental temperature shift for ^{87}Rb in a trap with a critical temperature $T_c \approx 280 \text{ nK}$ which lies about 3% below the noninteracting Bose gas temperature (see Fig. 7.9). Its thermal de Broglie length is calculated best in atomic units. Then the fundamental length scale is the Bohr radius $a_H = \hbar/M_p c \alpha$, where M_p is the proton mass and $\alpha \approx 1/137.035$ the fine-structure constant. The fundamental energy scale is $E_H = M_e c^2 \alpha^2$. Writing now the thermal de Broglie length at the critical temperature as

$$\frac{a}{\ell_c} = \frac{2\pi\hbar^2}{Mk_B T_c} = \sqrt{2\pi} \sqrt{\frac{E_H}{k_B T_c}} \sqrt{\frac{M_e}{87M_p}} a_H, \quad (7.211)$$

we estimate with $\sqrt{E_H/k_B T_c} \approx \sqrt{27.21 \text{ eV}/(280 \times 10^{-9}/11\,604.447 \text{ eV})} \approx 1.06 \times 10^6$ and $\sqrt{M_e/87M_p} \approx \sqrt{0.511 \text{ eV}/(87 \times 938.27 \text{ eV})} \approx 0.002502$ such that $\ell_c \approx 6646 a_H$.

The triplet s-wave scattering length of ^{87}Rb is $a \approx (106 \pm 4) a_H$ such that we find from (7.203)

$$\frac{\Delta T_c}{T_c^{(0)}} \approx -5.4\%, \quad (7.212)$$

which is compatible with the experimentally data of the trap in Fig. 7.9.

Let us finally mention recent studies of more realistic systems in which bosons in a trap interact with longer-range interactions [45].

7.3 Gas of Free Fermions

For fermions, the thermodynamic functions (7.32) and (7.33) contain the functions

$$\zeta_\nu^f(z) \equiv \sum_{w=1}^{\infty} (-1)^{w-1} \frac{z^w}{w^\nu}, \quad (7.213)$$

which starts out for small z like z . For $z = 1$, this becomes

$$\zeta_\nu^f(1) = \frac{1}{1} - \frac{1}{2^\nu} + \frac{1}{3^\nu} - \frac{1}{4^\nu} + \dots = \sum_{k=0}^{\infty} \frac{1}{k^\nu} - 2^{1-\nu} \sum_{k=0}^{\infty} \frac{1}{k^\nu} = (1 - 2^{1-\nu}) \zeta(\nu). \quad (7.214)$$

In contrast to $\zeta_\nu(z)$ in Eq. (7.34) this function is perfectly well-defined for all chemical potentials by analytic continuation. The reason is the alternating sign in the series (7.213). The analytic continuation is achieved by expressing $\zeta_\nu^f(z)$ as an integral by analogy with (7.39), (7.40):

$$\zeta_n^f(z) \equiv \frac{1}{\Gamma(n)} i_n^f(\alpha), \quad (7.215)$$

where $i_n^f(\alpha)$ are the integrals

$$i_n^f(\alpha) \equiv \int_0^\infty d\varepsilon \frac{\varepsilon^{n-1}}{e^{\varepsilon-\alpha} + 1}. \quad (7.216)$$

In the integrand we recognize the Fermi distribution function of Eq. (3.111), in which $\omega\hbar\beta$ is replaced by $\varepsilon - \alpha$:

$$n_\varepsilon^f = \frac{1}{e^{\varepsilon-\alpha} + 1}. \quad (7.217)$$

The quantity ε plays the role of a reduced energy $\varepsilon = E/k_B T$, and α is a reduced chemical potential $\alpha = \mu/k_B T$.

Let us also here express the grand-canonical free energy F_G in terms of the functions $i_n^f(\alpha)$. Combining Eqs. (7.32), (7.213), and (7.216) we obtain for fermions with $g_S = 2S + 1$ spin orientations:

$$F_G = -\frac{1}{\beta} Z_0(\beta) \frac{g_S}{\Gamma(D/2+1)} i_{D/2+1}^f(\beta\mu) = -\frac{1}{\beta\Gamma(D/2+1)} \frac{g_S V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \frac{\varepsilon^{D/2}}{e^{\varepsilon-\beta\mu} + 1}, \quad (7.218)$$

and the integral can be brought by partial integration to the form

$$F_G = -\frac{1}{\beta\Gamma(D/2)} \frac{g_S V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \varepsilon^{D/2-1} \log(1 + e^{-\varepsilon+\beta\mu}). \quad (7.219)$$

Recalling Eq. (7.47), this can be rewritten as a sum over momenta of oscillators with energy $\hbar\omega_{\mathbf{p}} \equiv \mathbf{p}^2/2M$:

$$F_G = -\frac{g_S}{\beta} \sum_{\mathbf{p}} \log(1 + e^{-\beta\hbar\omega_{\mathbf{p}}+\beta\mu}). \quad (7.220)$$

This free energy will be studied in detail in Section 7.14.

The particle number corresponding to the integral representations (7.219) and (7.220) is

$$N = -\frac{\partial}{\partial \mu} F_G = \frac{1}{\Gamma(D/2)} \frac{g_S V_D}{\sqrt{2\pi\hbar^2\beta/M}^D} \int_0^\infty d\varepsilon \frac{\varepsilon^{D/2-1}}{e^{\varepsilon+\beta\mu} - 1} = g_S \sum_{\mathbf{p}} \frac{1}{e^{\beta\hbar\omega_{\mathbf{p}}+\beta\mu} - 1}. \quad (7.221)$$

Recalling the reduced density of states, this may be written with the help of the Fermi distribution function n_ε^f of Eq. (7.217) as

$$N = g_S V_D \int_0^\infty d\varepsilon N_\varepsilon n_\varepsilon^f. \quad (7.222)$$

The Bose function contains a pole at $\alpha = 0$ which prevents the existence of a solution for positive α . In the analytically continued fermionic function (7.215), on the other hand, the point $\alpha = 0$ is completely regular.

Consider now a Fermi gas close to zero temperature which is called the degenerate limit. Then the reduced variables $\varepsilon = E/k_B T$ and $\alpha = \mu/k_B T$ become very large and the distribution function (7.217) reduces to

$$n_\varepsilon^f = \begin{cases} 1 & \text{for } \varepsilon < \alpha \\ 0 & \text{for } \varepsilon > \alpha \end{cases} = \Theta(\varepsilon - \alpha). \quad (7.223)$$

All states with energy E lower than the chemical potential μ are filled, all higher states are empty. The chemical potential μ at zero temperature is called *Fermi energy* E_F :

$$\mu|_{T=0} \equiv E_F. \quad (7.224)$$

The Fermi energy for a given particle number N in a volume V_D is found by performing the integral (7.222) at $T = 0$:

$$N = g_S V_D \int_0^{E_F} d\varepsilon N_\varepsilon = \frac{1}{\Gamma(D/2+1)} \frac{g_S V_D E_F^{D/2}}{\sqrt{2\pi\hbar^2/M}^D} = \frac{1}{\Gamma(D/2+1)} \frac{g_S V_D}{\sqrt{4\pi}^D} \left(\frac{p_F}{\hbar}\right)^D, \quad (7.225)$$

where

$$p_F \equiv \sqrt{2ME_F} \quad (7.226)$$

is the *Fermi momentum* associated with the Fermi energy. Equation (7.225) is solved for E_F by

$$E_F = \frac{2\pi\hbar^2}{M} \left[\frac{\Gamma(D/2+1)}{g_S} \right]^{2/D} \left(\frac{N}{V_D} \right)^{2/D}, \quad (7.227)$$

and for the Fermi momentum by

$$p_F = 2\sqrt{\pi}\hbar \left[\frac{\Gamma(D/2+1)}{g_S} \right]^{1/D} \left(\frac{N}{V_D} \right)^{1/D} \hbar. \quad (7.228)$$

Note that in terms of the particle number N , the density of states per unit energy interval and volume can be written as

$$N_\varepsilon \equiv \frac{d N}{2 V_D} \sqrt{\frac{k_B T}{E_F}} \varepsilon^{D/2-1}. \quad (7.229)$$

As the gas is heated slightly, the degeneracy in the particle distribution function in Eq. (7.223) softens. The degree to which this happens is governed by the size of the ratio kT/E_F . It is useful to define a characteristic temperature, the so-called *Fermi temperature*

$$T_F \equiv \frac{E_F}{k_B} = \frac{1}{k_B} \frac{p_F^2}{2M}. \quad (7.230)$$

For electrons in a metal, p_F is of the order of $\hbar/1\text{\AA}$. Inserting $M = m_e = 9.109558 \times 10^{-28}$ g, further $k_B = 1.380622 \times 10^{-16}$ erg/K and $\hbar = 6.0545919 \times 10^{-27}$ erg sec, we see that T_F has the order of magnitude

$$T_F \approx 44\,000\text{K}. \quad (7.231)$$

Hence, even far above room temperatures the relation $T/T_F \ll 1$ is quite well fulfilled and can be used as an expansion parameter in evaluating the thermodynamic properties of the electron gas at nonzero temperature.

Let us calculate the finite- T effects in $D = 3$ dimensions. From Eq. (7.225) we obtain

$$N = N(T, \mu) \equiv \frac{g_S V}{l_e^3 (\hbar\beta)} \frac{2}{\sqrt{\pi}} i_{3/2}^f \left(\frac{\mu}{k_B T} \right). \quad (7.232)$$

Expressing the particle number in terms of the Fermi energy with the help of Eq. (7.225), we obtain for the temperature dependence of the chemical potential an equation analogous to (7.54):

$$1 = \left(\frac{k_B T}{E_F} \right)^{3/2} \frac{3}{2} i_{3/2}^f \left(\frac{\mu}{k_B T} \right). \quad (7.233)$$

To evaluate this equation, we write the integral representation (7.216) as

$$\begin{aligned} i_n^f(\alpha) &= \int_{-\alpha}^{\infty} dx \frac{(\alpha+x)^{n-1}}{e^x+1} \\ &= \int_0^{\alpha} dx \frac{(\alpha-x)^{n-1}}{e^{-x}+1} + \int_0^{\infty} dx \frac{(\alpha+x)^{n-1}}{e^x+1}. \end{aligned} \quad (7.234)$$

where $\varepsilon = x + \alpha$. In the first integral we substitute $1/(e^{-x}+1) = 1 - 1/(e^x+1)$, and obtain

$$i_n^f(\alpha) = \int_0^{\alpha} dx x^{n-1} + \int_0^{\infty} dx \frac{(\alpha+x)^{n-1} - (\alpha-x)^{n-1}}{e^x+1} + \int_{\alpha}^{\infty} dx \frac{(\alpha-x)^{n-1}}{e^x+1}. \quad (7.235)$$

In the limit $\alpha \rightarrow \infty$, only the first term survives, whereas the last term is exponentially small, so that it can be ignored in a series expansion in powers of $1/\alpha$. The second term is expanded in such a series:

$$2 \sum_{k=\text{odd}}^{\infty} \binom{n-1}{k} \alpha^{n-1-k} \int_0^{\infty} dx \frac{x^k}{e^x + 1} = 2 \sum_{k=\text{odd}} \frac{(n-1)!}{(n-1-k)!} \alpha^{n-1-k} (1 - 2^{-k}) \zeta(k+1). \quad (7.236)$$

In the last equation we have used the integral formula for Riemann's ζ -function⁴

$$\int_0^{\infty} dx \frac{x^{\nu-1}}{e^{\mu x} + 1} = \mu^{-\nu} (1 - 2^{1-\nu}) \zeta(\nu). \quad (7.237)$$

At even positive and odd negative integer arguments, the zeta function is related to the Bernoulli numbers by Eq. (2.569). The lowest values of $\zeta(x)$ occurring in the expansion (7.236) are $\zeta(2)$, $\zeta(4)$, \dots , whose values were given in (2.571), so that the expansion of $i_n^f(\alpha)$ starts out like

$$i_n^f(\alpha) = \frac{1}{n} \alpha^n + 2(n-1) \frac{1}{2} \zeta(2) \alpha^{n-2} + 2(n-1)(n-2)(n-3) \frac{7}{8} \zeta(4) \alpha^{n-4} + \dots \quad (7.238)$$

Inserting this into Eq. (7.233) where $n = 3/2$, we find the low-temperature expansion

$$1 = \left(\frac{k_B T}{E_F} \right)^{3/2} \frac{3}{2} \left[\frac{2}{3} \left(\frac{\mu}{k_B T} \right)^{3/2} + \frac{\pi^2}{12} \left(\frac{\mu}{k_B T} \right)^{-1/2} + \frac{7\pi^4}{3 \cdot 320} \left(\frac{\mu}{k_B T} \right)^{-5/2} \dots \right], \quad (7.239)$$

implying for μ the expansion

$$\mu = E_F \left[1 - \frac{\pi^2}{12} \left(\frac{k_B T}{E_F} \right)^2 + \frac{7\pi^4}{720} \left(\frac{k_B T}{E_F} \right)^4 + \dots \right]. \quad (7.240)$$

These expansions are asymptotic. They have a zero radius of convergence, diverging for any T . They can, however, be used for calculations if T is sufficiently small or at all T after a variational resummation à la Section 5.18.

We now turn to the grand-canonical free energy F_G . In terms of the function (7.216), this reads

$$F_G = -\frac{1}{\beta} \frac{g_S V}{l_e^3 (\hbar \beta)} \frac{1}{\Gamma(5/2)} i_{5/2}^f(\alpha). \quad (7.241)$$

Using again (7.238), this has the expansion

$$F_G(T, \mu, V) = F_G(0, \mu, V) \left[1 + \frac{5\pi^2}{8} \left(\frac{k_B T}{\mu} \right)^2 - \frac{7\pi^4}{384} \left(\frac{k_B T}{\mu} \right)^4 + \dots \right], \quad (7.242)$$

where

$$F_G(0, \mu, V) \equiv -\frac{2}{5} g_S V \frac{\sqrt{2} M^{3/2}}{3\pi^2 \hbar^3} (\mu)^{3/2} \mu = -\frac{2}{5} N \left(\frac{\mu}{E_F} \right)^{3/2} \mu.$$

⁴I.S. Gradshteyn and I.M. Ryzhik, *op. cit.*, Formula 3.411.3.

By differentiating F_G with respect to the temperature at fixed μ , we obtain the low-temperature behavior of the entropy

$$S = k_B \frac{\pi^2 k_B T}{2 E_F} N + \dots \quad (7.243)$$

From this we find a specific heat at constant volume

$$C = T \frac{\partial S}{\partial T} \Big|_{V,N} \stackrel{T \approx 0}{\approx} S = k_B \frac{\pi^2 k_B T}{2 E_F} N + \dots \quad (7.244)$$

This grows linearly with increasing temperature and saturates at the constant value $3k_B N/2$ which obeys the Dulong-Petit law of Section 2.12 corresponding to three kinetic and no potential harmonic degrees of freedom in the classical Hamiltonian $\mathbf{p}^2/2M$. See Fig. 7.11 for the full temperature behavior. The linear behavior is

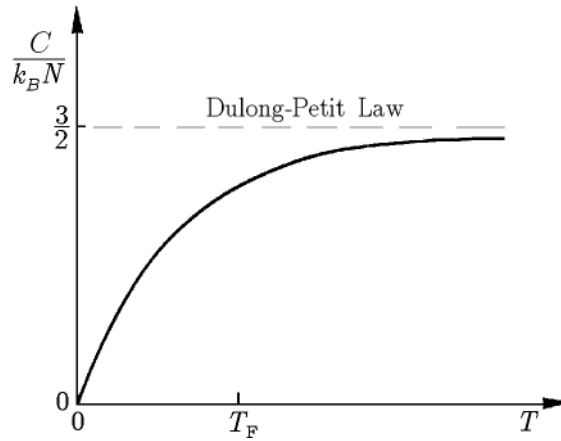

Figure 7.11 Temperature behavior of specific heat of free Fermi gas. As in the free Bose gas, the Dulong-Petit rule gives a high-temperature limit $3k_B N/2$ for the three harmonic kinetic degrees of freedom in the classical Hamiltonian $\mathbf{p}^2/2M$. There are no harmonic potential degrees of freedom.

due to the progressive softening near the surface of the Fermi distribution which makes more and more electrons thermally excitable. It is detected experimentally in metals at low temperature where the contribution of lattice vibrations freezes out as $(T/T_D)^3$. Here T_D is the Debye temperature which characterizes the elastic stiffness of the crystal and ranges from $T_D \approx 90\text{K}$ in soft metals like lead over $T_D \approx 389\text{K}$ for aluminum to $T_D \approx 1890\text{K}$ for diamond. The experimental size of the slope is usually larger than the free electron gas value in (7.244). This can be explained mainly by the interactions with the lattice which result in a large effective mass $M_{\text{eff}} > M$.

Note that the quantity $F_G(0, \mu, V)$ is temperature dependent via the chemical potential μ . Inserting (7.240) into (7.242) we find the complete T -dependence

$$F_G(T, \mu, V) = F_G(0, E_F, V) \left[1 + \frac{5\pi^2}{12} \left(\frac{k_B T}{E_F} \right)^2 - \frac{\pi^4}{16} \left(\frac{k_B T}{E_F} \right)^4 + \dots \right], \quad (7.245)$$

where

$$F_G(0, E_F, V) = -\frac{2}{5}NE_F. \quad (7.246)$$

As in the boson gas, we have a relation (7.61) between energy and grand-canonical free energy:

$$E = -\frac{3}{2}F_G, \quad (7.247)$$

such that equation (7.245) supplies us with the low-temperature behavior of the internal energy:

$$E = \frac{3}{5}NE_F \left[1 + \frac{5\pi^2}{12} \left(\frac{k_B T}{E_F} \right)^2 - \frac{\pi^4}{16} \left(\frac{k_B T}{E_F} \right)^4 + \dots \right]. \quad (7.248)$$

The first term is the energy of the zero-temperature Fermi sphere. Using the relation $c_V = \partial E/V\partial T$, the second term yields once more the leading $T \rightarrow 0$ -behavior (7.244) of specific heat.

This behavior of the specific heat can be observed in metals where the conduction electrons behave like a free electron gas. Due to *Bloch's theorem*, a single electron in a perfect lattice behaves just like a free particle. For many electrons, this is still approximately true, if the mass of the electrons is replaced by an effective mass.

Another important macroscopic system where (7.244) can be observed is a liquid consisting of the fermionic isotope ^3He . There are two electron spins and an odd number of nucleon spins which make this atom a fermion. Also there the strong interactions in the liquid produce a screening effect which raises to an effective value of the mass to 8 times that of the atom.

7.4 Statistics Interaction

First, we consider only two identical particles; the generalization to n particles will be obvious. For simplicity, we ignore the one-body potentials $V(\mathbf{x}^{(\nu)})$ in (7.2) since they cause only inessential complications. The total orbital action is then

$$\mathcal{A} = \int_{t_a}^{t_b} dt \left[\frac{M^{(1)}}{2} \dot{\mathbf{x}}^{(1)2} + \frac{M^{(2)}}{2} \dot{\mathbf{x}}^{(2)2} - V_{\text{int}}(\mathbf{x}^{(1)} - \mathbf{x}^{(2)}) \right]. \quad (7.249)$$

The standard change of variables to center-of-mass and relative coordinates

$$\mathbf{X} = (M^{(1)}\mathbf{x}^{(1)} + M^{(2)}\mathbf{x}^{(2)})/(M^{(1)} + M^{(2)}), \quad \mathbf{x} = (\mathbf{x}^{(1)} - \mathbf{x}^{(2)}), \quad (7.250)$$

respectively, separates the action into a free center-of-mass and a relative action

$$\mathcal{A} = \mathcal{A}_{\text{CM}} + \mathcal{A}_{\text{rel}} = \int_{t_a}^{t_b} dt \frac{M}{2} \dot{\mathbf{X}}^2 + \int_{t_a}^{t_b} dt \left[\frac{\mu}{2} \dot{\mathbf{x}}^2 - V_{\text{int}}(\mathbf{x}) \right], \quad (7.251)$$

with a total mass $M = M^{(1)} + M^{(2)}$ and a reduced mass $\mu = M^{(1)}M^{(2)}/(M^{(1)} + M^{(2)})$. Correspondingly, the time evolution amplitude of the two-body system factorizes

into that of an ordinary free particle of mass M , $(\mathbf{X}_b t_b | \mathbf{X}_a t_a)$, and a relative amplitude $(\mathbf{x}_b t_b | \mathbf{x}_a t_a)$. The path integral for the center-of-mass motion is solved as in Chapter 2. Only the relative amplitude is influenced by the particle statistics and needs a separate treatment for bosons and fermions.

First we work in one dimension only. Many of the formulas arising in this case are the same as those of Section 6.2, where we derived the path integral for a particle moving in a half-space $x = r > 0$; only the interpretation is different. We take care of the indistinguishability of the particles by restricting x to the positive semi-axis $x = r \geq 0$; the opposite vector $-x$ describes an identical configuration. The completeness relation of local states reads therefore

$$\int_0^\infty dr |r\rangle \langle r| = 1. \quad (7.252)$$

To write down the orthogonality relation, we must specify the bosonic or fermionic nature of the wave functions. Since these are symmetric or antisymmetric, respectively, we express $\langle r_b | r_a \rangle$ in terms of the complete set of functions with these symmetry properties:

$$\langle r_b | r_a \rangle = 2 \int_0^\infty \frac{dp}{\pi \hbar} \begin{Bmatrix} \cos pr_b / \hbar & \cos pr_a / \hbar \\ \sin pr_b / \hbar & \sin pr_a / \hbar \end{Bmatrix}. \quad (7.253)$$

This may be rewritten as

$$\langle r_b | r_a \rangle = \int_{-\infty}^\infty \frac{dp}{2\pi \hbar} \left(e^{ip(r_b - r_a)/\hbar} \pm e^{ip(r_b + r_a)/\hbar} \right) = \delta(r_b - r_a) \pm \delta(r_b + r_a). \quad (7.254)$$

The infinitesimal time evolution amplitude of relative motion is then, in the canonical formulation,

$$\begin{aligned} \langle r_n \epsilon | r_{n-1} 0 \rangle &= \langle r_n | e^{-i\epsilon \hat{H}_{\text{rel}}/\hbar} | r_{n-1} \rangle \\ &= \int_{-\infty}^\infty \frac{dp}{2\pi \hbar} \left(e^{ip(r_n - r_{n-1})/\hbar} \pm e^{ip(r_n + r_{n-1})/\hbar} \right) e^{-i\epsilon H_{\text{rel}}(p, r_n)/\hbar}, \end{aligned} \quad (7.255)$$

where $H_{\text{rel}}(p, x)$ is the Hamiltonian of relative motion associated with the action \mathcal{A}_{rel} in Eq. (7.251). By combining $N + 1$ factors, we find the time-sliced amplitude

$$\begin{aligned} \langle r_b t_b | r_a t_a \rangle &= \prod_{n=1}^N \left[\int_0^\infty dr_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^\infty \frac{dp_n}{2\pi \hbar} \right] \\ &\times \left\{ \exp \left[\frac{i}{\hbar} \sum_{n=1}^{N+1} p_n (r_n - r_{n-1}) \right] \pm \exp \left[\frac{i}{\hbar} \sum_{n=1}^{N+1} p_n (r_n + r_{n-1}) \right] \right\} e^{-\frac{i}{\hbar} \epsilon \sum_{n=1}^{N+1} H_{\text{rel}}(p_n, r_n)}, \end{aligned} \quad (7.256)$$

valid for bosons and fermions, respectively. By extending the radial integral over the entire space it is possible to remove the term after the \pm sign by writing

$$\begin{aligned} \langle r_b t_b | r_a t_a \rangle &= \sum_{x_b = \pm r_b} \prod_{n=1}^N \left[\int_{-\infty}^\infty dx_n \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^\infty \frac{dp_n}{2\pi \hbar} \right] \\ &\times \exp \left\{ \frac{i}{\hbar} \sum_{a=1}^{N+1} [p_n (x_n - x_{n-1}) - \epsilon H_{\text{rel}}(p_n, x_n) + \hbar \pi (\sigma(x_n) - \sigma(x_{n-1}))] \right\}, \end{aligned} \quad (7.257)$$

where the function $\sigma(x)$ vanishes identically for bosons while being equal to

$$\sigma(x) = \Theta(-x) \quad (7.258)$$

for fermions, where $\Theta(x)$ is the Heaviside function (1.313). As usual, we have identified $x_b \equiv x_{N+1}$ and $x_a \equiv x_0$ which is equal to r_a . The final sum over $x_b = \pm r_b$ accounts for the indistinguishability of the two orbits. The phase factors $e^{i\pi\sigma(x_n)}$ give the necessary minus signs when exchanging two fermion positions.

Let us use this formula to calculate explicitly the path integral for a free two-particle relative amplitude. In the bosonic case with a vanishing σ -term, we simply obtain the free-particle amplitude summed over the final positions $\pm r_b$:

$$(r_b t_b | r_a t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/\mu}} \left\{ \exp \left[\frac{i\mu}{\hbar} \frac{(r_b - r_a)^2}{2(t_b - t_a)} \right] + (r_b \rightarrow -r_b) \right\}. \quad (7.259)$$

For fermions, the phases $\sigma(x_n)$ in (7.257) cancel each other successively, except for the boundary term

$$e^{i\pi(\sigma(x_b) - \sigma(x_a))}. \quad (7.260)$$

When summing over $x_b = \pm r_b$ in (7.257), this causes a sign change of the term with $x_b = -r_b$ and leads to the antisymmetric amplitude

$$(r_b t_b | r_a t_a) = \frac{1}{\sqrt{2\pi\hbar i(t_b - t_a)/\mu}} \left\{ \exp \left[\frac{i\mu}{\hbar} \frac{(r_b - r_a)^2}{2(t_b - t_a)} \right] - (r_b \rightarrow -r_b) \right\}. \quad (7.261)$$

Let us also write down the continuum limit of the time-sliced action (7.257). It reads

$$\mathcal{A} = \mathcal{A}_{\text{rel}} + \mathcal{A}_{\text{f}} = \int_{t_a}^{t_b} dt [p\dot{x} - H_{\text{rel}}(p, x) + \hbar\pi\dot{x}(t)\partial_x\sigma(x(t))]. \quad (7.262)$$

The last term is the desired Fermi statistics interaction. It can also be written as

$$\mathcal{A}_{\text{f}} = -\hbar\pi \int_{t_a}^{t_b} dt \dot{x}(t)\delta(x(t)) = \hbar\pi \int_{t_a}^{t_b} dt \partial_t \Theta(-x(t)). \quad (7.263)$$

The right-hand expression shows clearly the pure boundary character of \mathcal{A}_{f} , which does not change the equations of motion. Such an interaction is called a *topological interaction*.

Since the integrals in (7.257) over x and p now cover the *entire* phase space and $\sigma(x)$ enters only at the boundaries of the time axis, it is possible to add to the action any potential $V_{\text{int}}(r)$. As long as the ordinary path integral can be performed, also the path integral with the additional σ -terms in (7.257) can be done immediately.

It is easy to generalize this result to any number of fermion orbits $x^{(\nu)}(t)$, $\nu = 1, \dots, n$. The statistics interaction is then $\sum_{\nu < \nu'} \mathcal{A}_{\text{f}}[x^{(\nu, \nu')}]$ with the distance vectors $x^{(\nu, \nu')} \equiv x^{(\nu)} - x^{(\nu')}$. When summing over all permuted final positions, the

many-fermion wave functions become antisymmetric. The amplitude is given by the generalization of Eq. (7.257):

$$\begin{aligned} (x_b^{(\nu_b)}; t_b | x_a^{(\nu_a)}; t_a) &= \sum_{p(\nu_b)} \prod_{\nu=1}^n \left\{ \prod_{n=1}^N \left[\int_{-\infty}^{\infty} dx_n^{(\nu)} \right] \prod_{n=1}^{N+1} \left[\int_{-\infty}^{\infty} \frac{dp_n^{(\nu)}}{2\pi\hbar} \right] \right\} \\ &\times \exp \left(\frac{i}{\hbar} \sum_{n=1}^{N+1} \left\{ \sum_{\nu=1}^n [p_n^{(\nu)}(x_n^{(\nu)} - x_{n-1}^{(\nu)}) - \epsilon H_{\text{rel}}(p_n^{(\nu)}, x_n^{(\nu)})] \right. \right. \\ &\quad \left. \left. + \hbar\pi \sum_{\nu < \nu'} [\sigma(x_n^{(\nu, \nu')}) - \sigma(x_{n-1}^{(\nu, \nu')})] \right\} \right), \end{aligned} \quad (7.264)$$

where $\sum_{p(\nu_b)}$ denotes the sum over all permutations of the final positions. The phases $\exp[i\pi\sigma(x)]$ produce the complete antisymmetry for fermions.

Consider now two particles moving in a two-dimensional space. Let the relative motion be described in terms of polar coordinates. For distinguishable particles, the scalar product of localized states is

$$\begin{aligned} \langle r_b \varphi_b | r_a \varphi_a \rangle &= \int_0^\infty dk k \sum_{m=-\infty}^{\infty} i_m(kr_b) i_m(kr_a) \frac{1}{2\pi} e^{im(\varphi_b - \varphi_a)} \\ &= \frac{1}{\sqrt{r_b r_a}} \delta(r_b - r_a) \delta(\varphi_b - \varphi_a). \end{aligned} \quad (7.265)$$

This follows straightforwardly by expanding the exponentials $e^{i\mathbf{k}\mathbf{x}} = e^{ikr \cos \varphi}$ in the scalar product

$$\langle \mathbf{x}_b | \mathbf{x}_a \rangle = \int \frac{d^2k}{(2\pi)^2} e^{i\mathbf{k}\mathbf{x}_b} e^{-i\mathbf{k}\mathbf{x}_a} = \delta^{(2)}(\mathbf{x}_b - \mathbf{x}_a) \quad (7.266)$$

into Bessel functions, according to the well-known formula⁵

$$e^{a \cos \varphi} = \sum_{m=-\infty}^{\infty} i_m(a) e^{im\varphi}, \quad (7.267)$$

and by rewriting $\delta^{(2)}(\mathbf{x}_b - \mathbf{x}_a)$ as $(r_b r_a)^{-1/2} \delta(r_b - r_a) \delta(\varphi_b - \varphi_a)$. For indistinguishable particles, the angle φ is restricted to a half-space, say $\varphi \in [0, \pi)$. When considering bosons or fermions, the phase factor $e^{im(\varphi_b - \varphi_a)}$ must be replaced by $e^{im(\varphi_b - \varphi_a)} \pm e^{im(\varphi_b + \pi - \varphi_a)}$, respectively. In the product of such amplitudes in a time-sliced path integral, the \pm -terms in (7.256) can again be accounted for by completing the half-space in φ to the full space $[-\pi, \pi)$ and introducing the field $\sigma(\varphi)$. By including a Hamiltonian and returning to Euclidean coordinates x_1, x_2 , we arrive at the relative amplitude

$$(\mathbf{x}_b t_b | \mathbf{x}_a t) = \int \mathcal{D}^2x \int \frac{\mathcal{D}^2p}{2\pi} \left\{ \exp \left[\frac{i}{\hbar} \mathcal{A}_{\text{rel}} + \frac{i}{\hbar} \mathcal{A}_{\text{f}} \right] + (\mathbf{x}_b \rightarrow -\mathbf{x}_b) \right\}, \quad (7.268)$$

with an obvious time slicing as in (7.257).

⁵I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 6.633.1.

The Fermi statistics interaction \mathcal{A}_f looks in polar coordinates just like (7.263), but with x replaced by φ :

$$\mathcal{A}_f = \hbar\pi \int_{t_a}^{t_b} dt \dot{\varphi}(t) \partial_\varphi \sigma(\varphi(t)). \quad (7.269)$$

Adapting the step function $\sigma(\varphi)$ to the periodic nature of the variable φ , we continue this function periodically in φ . Equivalently, we replace it by a step function $\sigma_p(\varphi)$ which jumps by one unit at every integer multiple of π and write

$$\mathcal{A}_f = \hbar \int_{t_a}^{t_b} dt \dot{\mathbf{x}}(t) \cdot \mathbf{a}(\mathbf{x}(t)), \quad (7.270)$$

with a vector potential

$$\mathbf{a}(\mathbf{x}) \equiv \pi \nabla \sigma_p(\varphi). \quad (7.271)$$

When calculating particle distributions or partition functions which satisfy periodic boundary conditions, this coupling is invariant under local gauge transformations of the vector potential

$$\mathbf{a}(\mathbf{x}) \rightarrow \mathbf{a}(\mathbf{x}) + \nabla \Lambda(\mathbf{x}), \quad (7.272)$$

with smooth and single-valued functions $\Lambda(\mathbf{x})$, i.e., with $\Lambda(\mathbf{x})$ satisfying the integrability condition of Schwarz:

$$(\partial_i \partial_j - \partial_j \partial_i) \Lambda(\mathbf{x}) = 0. \quad (7.273)$$

Taking advantage of gauge invariance, we can in (7.271) replace $\sigma_p(\varphi)$ by *any* function of \mathbf{x} as long as it changes by one unit when going from φ_b to $\varphi_b + \pi$. A convenient choice is

$$\sigma_p(\mathbf{x}) = \frac{1}{\pi} \varphi(\mathbf{x}) \equiv \frac{1}{\pi} \arctan \frac{x_2}{x_1}. \quad (7.274)$$

With this, the statistics interaction (7.270) becomes

$$\mathcal{A}_f = \hbar \int_{t_a}^{t_b} dt \dot{\mathbf{x}} \partial_{\mathbf{x}} \varphi(\mathbf{x}) = \hbar \int_{t_a}^{t_b} dt \epsilon_{ij} \frac{x_i \dot{x}_j}{\mathbf{x}^2}, \quad (7.275)$$

where ϵ_{ij} is the antisymmetric unit tensor of Levi-Civita in two dimensions.

Just like the expression (7.263), this is a purely topological interaction. By comparison with (7.270), we identify the vector potential of the statistics interaction as

$$a_i(\mathbf{x}) = \partial_i \varphi = -\epsilon_{ij} \frac{x_j}{\mathbf{x}^2}. \quad (7.276)$$

The Fermi statistics remains obviously in operation if we choose, instead of the vector potential (7.276), an arbitrary odd multiple of it:

$$a_i(\mathbf{x}) = \partial_i \varphi = -(2n+1) \epsilon_{ij} \frac{x_j}{\mathbf{x}^2}, \quad n = 0, \pm 1, \pm 2, \dots \quad (7.277)$$

The even multiples

$$a_i(\mathbf{x}) = \partial_i \varphi = -2n\epsilon_{ij} \frac{x_j}{\mathbf{x}^2}, \quad n = 0, \pm 1, \pm 2, \dots, \quad (7.278)$$

on the other hand, give rise to Bose statistics.

For more than two particles, the amplitude (7.268) is generalized to the two-dimensional analog of Eq. (7.264). In one and two space dimensions we have thus succeeded in taking care of the indistinguishability of the particles and the fermionic nature by the simple statistics interaction terms (7.263) and (7.275). The indistinguishability of the particles requires that the path integral over all paths from the initial point \mathbf{x}_a to the final point \mathbf{x}_b has to be extended by those paths which run to the reflected point $-\mathbf{x}_b$. The statistics interaction guarantees the antisymmetry of the resulting amplitude.

7.5 Fractional Statistics

The above considerations raise an important question. Is it possible that particles with an arbitrary real multiple of the statistical gauge interaction (7.275) exist in nature? Such particles would show an unusual statistical behavior. If the prefactor is denoted by μ_0 and the statistics interaction reads

$$\mathcal{A}_f = \hbar\mu_0 \int_{t_a}^{t_b} dt \dot{\mathbf{x}} \cdot \nabla \varphi(\mathbf{x}) = \hbar\mu_0 \int_{t_a}^{t_b} dt \epsilon_{ij} \frac{x_i \dot{x}_j}{\mathbf{x}^2}, \quad (7.279)$$

an interchange of the orbital endpoints in the path integral gives rise to a phase factor $e^{i\pi\mu_0}$. If μ_0 is even or odd, the amplitude describes bosons or fermions, respectively. For rational values of μ_0 , however, the particles are neither one nor the other. They are called *anyons*. The phase of the amplitude returns to its initial value only after the particles have been rotated around each other several times. The statistical behavior of such particles will be studied in detail in Section 16.2. There we shall see that for two ordinary particles, an anyonic statistical behavior can be generated by a magnetic interaction. An interaction of the form (7.279) arises from an infinitesimally thin magnetic flux tube of strength $\Phi = \mu_0\Phi_0$ with $\Phi_0 = 2\pi\hbar c/e$. Indeed, the magnetic interaction is given by the gauge-invariant expression

$$\mathcal{A}_{\text{mg}} = \frac{e}{c} \int_{t_a}^{t_b} dt \dot{\mathbf{x}}(t) \mathbf{A}(\mathbf{x}(t)), \quad (7.280)$$

and the vector potential of a thin magnetic flux tube of flux Φ reads

$$A_i(\mathbf{x}) = \frac{\Phi}{2\pi} \partial_i \varphi = -\Phi \epsilon_{ij} \frac{x_j}{\mathbf{x}^2}. \quad (7.281)$$

For the flux $\Phi_0 = 2\pi\hbar c/e$ or an odd multiple thereof, the magnetic interaction coincides with the statistics interaction of two fermions (7.275). Bose statistics holds if Φ is zero or an even multiple of Φ_0 . The magnetic field can be chosen

to produce any value of μ_0 . This analogy will permit us to calculate the second virial coefficient of a gas of anyons in Section 16.3. There we shall also see that the statistical parameter μ_0 determines the behavior of the wave functions near the origin. While the wave functions of bosons and fermions carry either even or odd azimuthal angular momenta m , respectively, and vanish like $|\mathbf{x}|^m$ for $|\mathbf{x}| \rightarrow 0$, those of anyons can carry any integer m , behaving like $|\mathbf{x}|^{|m+\mu_0|}$ with a noninteger exponent.

We shall demonstrate in Section 16.2 that flux tubes whose flux Φ is an integer multiple of Φ_0 , i.e., those with a flux corresponding to Fermi or Bose statistics, have a vanishing scattering amplitude with respect to particles of charge e (*Aharonov-Bohm effect*).

Such flux tubes can be used as a theoretical artifact to construct the vector potential of a magnetic monopole. Although magnetic fields can have no sources, a monopole can be brought in from infinity inside an infinitely thin tube of flux $\Phi = n\Phi_0$ ($n = \text{integer}$), called a *Dirac string*. Since this cannot be detected by any electromagnetic scattering experiment the endpoint of the string behaves like a magnetic monopole.⁶ In an important aspect, the analogy between the magnetic and statistics interaction is not perfect and the present path integral is different from the one governing the magnetic scattering amplitude: The magnetic scattering amplitude deals with two different particles, one with an electric and the other with a magnetic charge. The paths are therefore summed with a fixed endpoint. In the statistics case, on the other hand, the sum includes the final point \mathbf{x}_b and the reflected point $-\mathbf{x}_b$.

For this reason, the magnetic analogy can be used to impose arbitrary statistics only upon two particles and not upon an ensemble of many identical particles. The analogy has nevertheless been useful to guide recent theoretical developments, in particular the explanation of the fractional quantum Hall effect (to be discussed in Sections 16.13–16.12).

Particles in two dimensions with fractional statistics have recently become a source of inspiration in field theory, leading to many new and interesting insights.

7.6 Second-Quantized Bose Fields

We have seen above that the path integral of a system with many identical particles can become quite cumbersome to handle. Fortunately, there exists a much simpler and more efficient path integral description of many-particle systems. In the Schrödinger formulation of quantum mechanics, it is possible to generalize the single-particle Schrödinger equation to an arbitrary and *variable* number of particles by letting the complex Schrödinger fields $\psi(\mathbf{x}, t)$ be *field operators* rather than complex *c*-numbers. These are denoted by $\hat{\psi}(\mathbf{x}, t)$ and postulated to satisfy the harmonic-oscillator commutation relations at each point \mathbf{x} in space. To impose properly such

⁶See also the discussion in H. Kleinert, Int. J. Mod. Phys. A 7, 4693 (1992) (<http://www.physik.fu-berlin.de/~kleinert/203>); Phys. Lett. B 246, 127 (1990) (*ibid.*[http/205](http://205)).

local quantization rules, space is discretized into little cubes of volume ϵ^3 , centered around the points $\mathbf{x}_n = \epsilon(n_1, n_2, n_3)$, with $n_{1,2,3}$ running through all integers. If we omit the subscripts \mathbf{n} , for brevity, the quantization rules are

$$\begin{aligned} [\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)] &= \delta_{\mathbf{x}\mathbf{x}'}, \\ [\hat{\psi}^\dagger(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)] &= 0, \\ [\hat{\psi}(\mathbf{x}, t), \hat{\psi}(\mathbf{x}', t)] &= 0. \end{aligned} \quad (7.282)$$

The commutativity of the operators at different places ensures the independence of the associated oscillators. Imposing the conditions (7.282) is referred to as *second quantization* or *field quantization*. One also speaks of a *quantization of particle number*. The commutation relations generate an infinite-dimensional Hilbert space at each space point \mathbf{x} . Applying the operator $\hat{\psi}^\dagger(\mathbf{x}, t)$ n times to the ground state of the harmonic oscillator $|0\rangle_{\mathbf{x}}$ at \mathbf{x} creates states with n excitations at \mathbf{x} :

$$|n, \mathbf{x}\rangle = \frac{1}{\sqrt{n!}} [\hat{\psi}^\dagger(\mathbf{x}, 0)]^n |0\rangle. \quad (7.283)$$

These states are interpreted as states describing n particles at the point \mathbf{x} . The ground state of all oscillators is

$$|0\rangle \equiv \prod_{\mathbf{x}} |0\rangle_{\mathbf{x}}. \quad (7.284)$$

It is called the *vacuum state* of the system. The total number of particles at each time is measured by the operator

$$\hat{N}(t) = \sum_{\mathbf{x}} \hat{\psi}^\dagger(\mathbf{x}, t) \hat{\psi}(\mathbf{x}, t). \quad (7.285)$$

The simplest classical action, whose quantum theory has the above structure, describes an ensemble of free bosons with a chemical potential μ :

$$\mathcal{A}[\psi^*, \psi] = \sum_{\mathbf{x}} \int_{t_a}^{t_b} dt \left[\psi^*(i\hbar\partial_t + \mu)\psi(\mathbf{x}, t) - \frac{\hbar^2}{2M} \psi^* \nabla_{\mathbf{x}} \bar{\nabla}_{\mathbf{x}} \psi(\mathbf{x}, t) \right]. \quad (7.286)$$

The symbols $\nabla_{\mathbf{x}}, \bar{\nabla}_{\mathbf{x}}$ denote the difference operators on the discretized three-dimensional space, each component $\nabla_i, \bar{\nabla}_i$ being defined in the same way as the difference operators $\nabla, \bar{\nabla}$ on the sliced time axis in Eqs. (2.97). The eigenvalues on a plane wave of momentum \mathbf{p} are

$$-i\hbar\nabla_i e^{i\mathbf{p}\mathbf{x}/\hbar} = P_i e^{i\mathbf{p}\mathbf{x}/\hbar}, \quad -i\hbar\bar{\nabla}_i e^{i\mathbf{p}\mathbf{x}/\hbar} = \bar{P}_i e^{i\mathbf{p}\mathbf{x}/\hbar}, \quad (7.287)$$

with

$$P_i = -i\frac{\hbar}{\epsilon} [e^{i\epsilon p_i/\hbar} - 1], \quad \bar{P}_i = P_i^*. \quad (7.288)$$

By Fourier decomposing the field

$$\psi(\mathbf{x}, t) = \sqrt{\frac{\epsilon^3}{V}} \sum_{\mathbf{p}} e^{i\mathbf{p}\mathbf{x}/\hbar} a_{\mathbf{p}}(t), \quad (7.289)$$

the difference operators $\nabla_{\mathbf{x}}, \bar{\nabla}_{\mathbf{x}}$ are diagonalized and the action is decomposed into a direct sum of fields $a_{\mathbf{p}}^*(t), a_{\mathbf{p}}(t)$ of a fixed momentum \mathbf{p} ,

$$\mathcal{A}[a^*, a] = \hbar \sum_{\mathbf{p}} \int_{t_a}^{t_b} dt \left[a_{\mathbf{p}}^*(t) i \partial_t a_{\mathbf{p}}(t) - \omega(\mathbf{p}) a_{\mathbf{p}}^*(t) a_{\mathbf{p}}(t) \right], \quad (7.290)$$

where $\omega(\mathbf{p})$ denotes the single-particle frequencies

$$\omega(\mathbf{p}) \equiv \frac{1}{\hbar} \left[\frac{|\mathbf{P}|^2}{2M} - \mu \right], \quad (7.291)$$

with

$$|\mathbf{P}|^2 \equiv \frac{\hbar^2}{\epsilon^2} \sum_i 2 \left[1 - \cos \left(\frac{\epsilon p_i}{\hbar} \right) \right]. \quad (7.292)$$

The extremization of (7.286) gives the field equation

$$\left(i \hbar \partial_t + \mu + \frac{\hbar^2}{2M} \nabla_{\mathbf{x}} \bar{\nabla}_{\mathbf{x}} \right) \psi(\mathbf{x}, t) = 0. \quad (7.293)$$

This is the ordinary free-particle Schrödinger equation (the *first-quantized* field equation), apart from a constant shift in the energy by the chemical potential μ . Recall that the chemical potential guarantees a fixed average particle number which, in experiments, is enforced by contact with an appropriate particle reservoir (see Section 1.17). In momentum space, the field equation reads

$$[i \partial_t - \omega(\mathbf{p})] a_{\mathbf{p}}(t) = 0.$$

Knowing the general relation between the operator and the path integral description of quantum mechanics, we expect that the above rules of second quantization of operators can be accounted for by assuming the field variables $a_{\mathbf{p}}^*(t)$ and $a_{\mathbf{p}}(t)$ in the action to be fluctuating *c*-number variables and summing over all their configurations with an amplitude $\exp\{(i/\hbar)\mathcal{A}[a^*, a]\}$. The precise form of this path integral can be inferred from the oscillator nature of the commutation relations (7.282). After the Fourier transform (7.289), the components $\hat{a}_{\mathbf{p}}(t), \hat{a}_{\mathbf{p}}^\dagger(t)$ satisfy

$$\begin{aligned} [\hat{a}_{\mathbf{p}}(t), \hat{a}_{\mathbf{p}'}^\dagger(t)] &= \delta_{\mathbf{p}\mathbf{p}'}, \\ [\hat{a}_{\mathbf{p}}^\dagger(t), \hat{a}_{\mathbf{p}}^\dagger(t)] &= 0, \\ [\hat{a}_{\mathbf{p}}(t), \hat{a}_{\mathbf{p}'}(t)] &= 0. \end{aligned} \quad (7.294)$$

Since the oscillators at different momenta \mathbf{p} are independent of each other and since the action is a direct sum, we may drop the subscript \mathbf{p} in the sequel and consider fields of a single momentum only.

The commutators (7.294) are the same as those of a harmonic oscillator, of course, obtained from the usual canonical commutators

$$[\hat{p}, \hat{x}] = -i\hbar \quad (7.295)$$

by the canonical transformation

$$\hat{a}^\dagger = \sqrt{M/2\hbar\omega}(\omega\hat{x} - i\hat{p}/M), \quad \hat{a} = \sqrt{M/2\hbar\omega}(\omega\hat{x} + i\hat{p}/M). \quad (7.296)$$

Note that within the present context, the oscillator momentum \hat{p} is the conjugate momentum of the field operator and has no relation to the particle momentum \mathbf{p} (there exists a field operator for each particle momentum \mathbf{p}). The transformation (7.296) changes the Hamiltonian of the harmonic oscillator

$$\hat{H}_\omega = \frac{1}{2M}\hat{p}^2 + \frac{M\omega^2}{2}\hat{x}^2 \quad (7.297)$$

into the creation and annihilation operator form

$$\hat{H}_\omega = \frac{\hbar\omega}{2}(\hat{a}^\dagger\hat{a} + \hat{a}\hat{a}^\dagger). \quad (7.298)$$

The classical action in the canonical form

$$\mathcal{A}[p, q] = \int_{t_a}^{t_b} dt [p\dot{q} - H_\omega(p, q)] \quad (7.299)$$

turns into

$$\mathcal{A}[a^*, a] = \hbar \int_{t_a}^{t_b} dt (a^*i\partial_t a - \omega a^* a). \quad (7.300)$$

If one wants to describe quantum statistics, one has to replace $t \rightarrow -i\tau$ and use the Euclidean action (with $\beta = 1/k_B T$)

$$\mathcal{A}_e[a^*, a] = \hbar \int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \omega a^* a), \quad (7.301)$$

which coincides precisely with the action (7.290) for particles of a single momentum.

7.7 Fluctuating Bose Fields

We set up a path integral formulation which replaces this second-quantized operator structure. Since we have studied the harmonic oscillator extensively in real and imaginary time and since we know how to go back and forth between quantum-mechanical and -statistical expressions, we consider here only the case of imaginary time with the Euclidean action (7.301). For simplicity, we calculate only the partition function. The extension to density matrices is straightforward. Correlation functions will be discussed in detail in Chapter 18.

Since the action (7.300) of the harmonic oscillator is merely a rewritten canonical action (7.299), the partition function of the harmonic oscillator is given by the path

ref(2.339) integral [see (2.339)]
lab(2.187)
est(2.220)

$$Z_\omega = \oint \mathcal{D}x(\tau) \int \frac{\mathcal{D}p(\tau)}{2\pi\hbar} \exp \left[- \int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \omega a^* a) \right], \quad (7.302)$$

where the quantum-mechanical trace requires the orbits $x(\tau)$ to be periodic in $\tau \rightarrow \tau + \hbar\beta$, with a Fourier expansion

$$x(\tau) = \frac{1}{\sqrt{\hbar\beta}} \sum_{m=-\infty}^{\infty} x_m e^{-i\omega_m \tau}, \quad \omega_m = 2\pi m/\hbar\beta. \quad (7.303)$$

The momentum integrations are unrestricted.

If the momentum states were used as the diagonal basis for the derivation of the path integral, the measure would be $\int \mathcal{D}x \oint (\mathcal{D}p/2\pi\hbar)$. Then $p(\tau)$ is periodic under $\tau \rightarrow \tau + \hbar\beta$ and the $x(\tau)$ -integrations are unrestricted. This would give a different expression at the time-sliced level; the continuum limit $\epsilon \rightarrow 0$, however, would be the same.

Since the explicit conjugate variables in the action are now a and a^* , it is customary to express the measure of the path integral in terms of these variables and write

$$Z_\omega \equiv \oint \frac{\mathcal{D}a^*(\tau)\mathcal{D}a(\tau)}{\pi} \exp \left\{ - \int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \omega a^* a) \right\}, \quad (7.304)$$

where $\oint \mathcal{D}a^* \mathcal{D}a$ stands for the measure

$$\oint \mathcal{D}a^* \mathcal{D}a = \oint_{-\infty}^{\infty} \mathcal{D} \operatorname{Re} a \int_{-\infty}^{\infty} \mathcal{D} \operatorname{Im} a. \quad (7.305)$$

With the action being the time-sliced oscillator action, the result of the path integration in the continuum limit is known from (2.409) to be

$$Z_\omega = \frac{1}{2 \sinh(\hbar\omega\beta/2)}. \quad (7.306)$$

ref(2.409)
lab(2.240)
est(2.280)

In the context of second quantization, this is not really the desired result. For large β , the partition function (7.306) behaves like

$$Z_\omega \rightarrow e^{-\hbar\omega\beta/2}, \quad (7.307)$$

exhibiting in the exponent the oscillator ground-state energy $E_0 = \hbar\omega/2$. In the second-quantized interpretation, however, the ground state is the no-particle state. Hence its energy should be zero. In the operator formulation, this can be achieved by an appropriate operator ordering, choosing the Hamiltonian operator to be

$$\hat{H} = \hbar\omega \hat{a}^\dagger \hat{a}, \quad (7.308)$$

rather than the oscillator expression (7.298). In the path integral, the same goal is achieved by suitably time-slicing the path integral (7.304) and writing

$$Z_\omega^N = \prod_{n=0}^N \left[\int \frac{da_n^* da_n}{\pi} \right] \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_\omega^N \right\}, \quad (7.309)$$

with the sliced action

$$\mathcal{A}_\omega^N = \hbar \sum_{n=1}^N [a_n^* (a_n - a_{n-1}) + \epsilon \omega a_n^* a_{n-1}]. \quad (7.310)$$

Expressed in terms of the difference operator, it reads

$$\mathcal{A}_\omega^N = \hbar \epsilon \sum_{n=1}^N a_n^* [(1 - \epsilon \omega) \bar{\nabla} + \omega] a_n. \quad (7.311)$$

The $a(\tau)$ -orbits are taken to be periodic functions of τ , with a Fourier expansion

$$a(\tau) = \frac{1}{\sqrt{\hbar\beta}} \sum_{m=-\infty}^{\infty} a_m e^{-i\omega_m \tau}, \quad \omega_m = 2\pi m / \hbar\beta. \quad (7.312)$$

Note that in contrast to the coefficients x_m in expansion (7.303), a_m and a_{-m} are *independent* of each other, since $a(\tau)$ is complex. The periodicity of $a(\tau)$ arises as follows: In the time-sliced path integral derived in the x -basis with integration variables x_0, \dots, x_{N+1} and p_1, \dots, p_{N+1} , we introduce a fictitious momentum variable p_0 which is set identically equal to p_{N+1} . Then the time-sliced $\int_0^{\hbar\beta} d\tau p \dot{x}$ term, $\sum_{n=1}^{N+1} p_n \bar{\nabla} x_n$, can be replaced by $-\sum_{n=1}^{N+1} x_n \nabla p_n$ [see the rule of partial integration on the lattice, Eq. (2.103)] or by $-\sum_{n=1}^{N+1} x_n \bar{\nabla} p_n$. The first term in the time-sliced action (7.310) arises by symmetrizing the above two lattice sums.

In order to perform the integrals in (7.309), we make use of the Gaussian formula valid for $\text{Re } A > 0$,

$$\int \frac{da_n^* da_n}{\pi} e^{-a_n^* A_n a_n} = \frac{1}{A_n}, \quad \text{Re } A_n > 0. \quad (7.313)$$

By taking a product of N of these, we have

$$\prod_{n=0}^N \left[\int \frac{da_n^* da_n}{\pi} \right] e^{-\sum_n a_n^* A_n a_n} = \prod_{n=1}^{N+1} \frac{1}{A_n}, \quad \text{Re } A_n > 0. \quad (7.314)$$

This is obviously a special case of the matrix formula

$$Z = \prod_{n=0}^N \left[\int \frac{da_n^* da_n}{\pi} \right] e^{-\sum_{n,m} a_n^* A_{nm} a_m} = \frac{1}{\det A}, \quad (7.315)$$

in which the matrix $A = A^d$ has only diagonal elements with a positive real part. Now we observe that the measure of integration is certainly invariant under any unitary transformation of the components a_n :

$$a_n \rightarrow \sum_{n'} U_{n,n'} a_{n'}. \quad (7.316)$$

So is the determinant of A :

$$\det A \rightarrow \det (U A^d U^\dagger) = \det A^d. \quad (7.317)$$

But then formula (7.315) holds for any matrix A which can be diagonalized by a unitary transformation and has only eigenvalues with a positive real part. In the present case, the possibility of diagonalizing A is guaranteed by the fact that A satisfies $AA^\dagger = A^\dagger A$, i.e., it is a *normal* matrix. This property makes the Hermitian and anti-Hermitian parts of A commute with each other, allowing them to be diagonalized simultaneously.

In the partition function (7.309), the $(N+1) \times (N+1)$ matrix A has the form

$$A = \epsilon(1 - \epsilon\omega)\overline{\nabla} + \epsilon\omega = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 & -1 + \epsilon\omega \\ -1 + \epsilon\omega & 1 & 0 & \dots & 0 & 0 \\ 0 & -1 + \epsilon\omega & 1 & \dots & 0 & 0 \\ 0 & 0 & -1 + \epsilon\omega & \dots & 0 & 0 \\ \vdots & & & & & \vdots \\ 0 & 0 & 0 & \dots & -1 + \epsilon\omega & 1 \end{pmatrix}. \quad (7.318)$$

This matrix acts on a complex vector space. Its determinant can immediately be calculated by a repeated expansion along the first row [recall the calculations of the determinants (2.204) and (2.418)], giving

$$\det_{N+1} A = 1 - (1 - \epsilon\omega)^{N+1}. \quad (7.319)$$

Hence we obtain the time-sliced partition function

$$Z_\omega^N = \frac{1}{\det_{N+1}[\epsilon(1 - \epsilon\omega)\overline{\nabla} + \epsilon\omega]} = \frac{1}{1 - (1 - \epsilon\omega)^{N+1}}. \quad (7.320)$$

It is useful to introduce the auxiliary frequency

$$\bar{\omega}_e \equiv -\frac{1}{\epsilon} \log(1 - \epsilon\omega). \quad (7.321)$$

The subscript e records the Euclidean nature of the time [in analogy with the frequencies $\tilde{\omega}_e$ of Eq. (2.399)]. In terms of $\bar{\omega}_e$, Z_ω^N takes the form

$$Z_\omega^N = \frac{1}{1 - e^{-\beta\hbar\bar{\omega}_e}}. \quad (7.322) \quad \begin{array}{l} \text{ref(2.399)} \\ \text{lab(2.230)} \\ \text{est(2.270)} \end{array}$$

This is the well-known partition function of Bose particles for a single state of energy $\bar{\omega}_e$. It has the expansion

$$Z_\omega = 1 + e^{-\beta\hbar\bar{\omega}_e} + e^{-2\beta\hbar\bar{\omega}_e} + \dots, \quad (7.323)$$

in which the n th term exhibits the Boltzmann factor for an occupation of a particle state by n particles, in accordance with the Hamiltonian operator

$$\hat{H}_\omega = \hbar\bar{\omega}_e \hat{N} = \hbar\bar{\omega}_e a^\dagger a. \quad (7.324)$$

In the continuum limit $\epsilon \rightarrow 0$, the auxiliary frequency tends to ω ,

$$\bar{\omega}_\epsilon \xrightarrow{\epsilon \rightarrow 0} \omega, \quad (7.325)$$

and Z_ω^N reduces to

$$Z_\omega = \frac{1}{1 - e^{-\beta\hbar\omega}}. \quad (7.326)$$

The generalization of the partition function to a system with a time-dependent frequency $\Omega(\tau)$ reads

$$Z_\omega^N = \prod_{n=0}^N \left[\int \frac{da_n^\dagger da_n}{\pi} \right] \exp \left\{ -\frac{1}{\hbar} \mathcal{A}^N \right\}, \quad (7.327)$$

with the sliced action

$$\mathcal{A}_\omega^N = \hbar \sum_{n=1}^N [a_n^*(a_n - a_{n-1}) + \epsilon \Omega_n a_n^* a_{n-1}], \quad (7.328)$$

or, expressed in terms of the difference operator $\bar{\nabla}$,

$$\mathcal{A}_\omega^N = \hbar \epsilon \sum_{n=1}^N a_n^* [(1 - \epsilon \Omega_n) \bar{\nabla} + \Omega_n] a_n. \quad (7.329)$$

The result is

$$Z_\omega^N = \frac{1}{\det_{N+1} [\epsilon(1 - \epsilon \Omega) \bar{\nabla} + \epsilon \Omega]} = \frac{1}{1 - \prod_{n=0}^N (1 - \epsilon \Omega_n)}. \quad (7.330)$$

Here we introduce the auxiliary frequency

$$\bar{\Omega}_\epsilon \equiv -\frac{1}{(N+1)\epsilon} \sum_{n=0}^N \log(1 - \epsilon \Omega_n), \quad (7.331)$$

which brings Z_ω^N to the form

$$Z_\omega^N = \frac{1}{1 - e^{-\beta\hbar\bar{\Omega}_\epsilon}}. \quad (7.332)$$

For comparison, let us also evaluate the path integral directly in the continuum limit. Then the difference operator (7.318) becomes the differential operator

$$(1 - \epsilon\omega) \bar{\nabla} + \omega \rightarrow \partial_\tau + \omega, \quad (7.333)$$

acting on periodic complex functions $e^{-i\omega_m\tau}$ with the Matsubara frequencies ω_m . Hence the continuum partition function of a harmonic oscillator could be written as

$$\begin{aligned} Z_\omega &= \oint \frac{\mathcal{D}a^* \mathcal{D}a}{\pi} \exp \left[-\int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \omega a^* a) \right] \\ &= \mathcal{N}_\omega \frac{1}{\det(\partial_\tau + \omega)}. \end{aligned} \quad (7.334)$$

The normalization constant is fixed by comparison with the time-sliced result. The operator $\partial_\tau + \omega$ has the eigenvalues $-i\omega_m + \omega$. The product of these is calculated by considering the ratios with respect to the $\omega = 0$ -values

$$\prod_{m=-\infty, \neq 0}^{\infty} \frac{-i\omega_m + \omega}{-i\omega_m} = \frac{\sinh(\hbar\omega\beta/2)}{\hbar\omega\beta/2}. \quad (7.335)$$

This product is the ratio of functional determinants

$$\frac{\det(\partial_\tau + \omega)}{\det'(\partial_\tau)} = \omega \frac{\sinh(\hbar\omega\beta/2)}{\hbar\omega\beta/2}, \quad (7.336)$$

where the prime on the determinant with $\omega = 0$ denotes the omission of the zero frequency $\omega_0 = 0$ in the product of eigenvalues; the prefactor ω accounts for this.

Note that this ratio formula of continuum fluctuation determinants gives naturally only the harmonic oscillator partition function (7.306), not the second-quantized one (7.322). Indeed, after fixing the normalization factor \mathcal{N}_ω in (7.334), the path integral in the continuum formulation can be written as

$$\begin{aligned} Z_\omega &= \oint \frac{\mathcal{D}a^* \mathcal{D}a}{\pi} \exp \left[- \int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \omega a^* a) \right] \\ &= \frac{k_B T}{\hbar} \frac{\det'(\partial_\tau)}{\det(\partial_\tau + \omega)} = \frac{1}{2 \sinh(\hbar\omega\beta/2)}. \end{aligned} \quad (7.337)$$

In the continuum, the relation with the oscillator fluctuation factor can be established most directly by observing that in the determinant, the operator $\partial_\tau + \omega$ can be replaced by the conjugate operator $-\partial_\tau + \omega$, since all eigenvalues come in complex-conjugate pairs, except for the $m = 0$ -value, which is real. Hence the determinant of $\partial_\tau + \omega$ can be substituted everywhere by

$$\det(\partial_\tau + \omega) = \det(-\partial_\tau + \omega) = \sqrt{\det(-\partial_\tau^2 + \omega^2)}, \quad (7.338)$$

rewriting the partition function (7.337) as

$$\begin{aligned} Z_\omega &= \frac{k_B T}{\hbar} \frac{\det'(\partial_\tau)}{\det(\partial_\tau + \omega)} \\ &= \frac{k_B T}{\hbar} \left[\frac{\det'(-\partial_\tau^2)}{\det(-\partial_\tau^2 + \omega^2)} \right]^{1/2} = \frac{1}{2 \sinh(\hbar\omega\beta/2)}, \end{aligned} \quad (7.339)$$

where the second line contains precisely the oscillator expressions (2.396).

ref(2.396)

A similar situation holds for an arbitrary time-dependent frequency where the partition function is

lab(2.227)

est(2.268)

$$\begin{aligned} Z_{\Omega(\tau)} &= \oint \frac{\mathcal{D}a^*(\tau) \mathcal{D}a(\tau)}{\pi} \exp \left\{ - \int_0^{\hbar\beta} d\tau \left[a^\dagger \partial_\tau a + \Omega(\tau) a^\dagger a \right] \right\} \\ &= \frac{k_B T}{\hbar} \left[\frac{\det'(-\partial_\tau^2)}{\det(-\partial_\tau^2 + \Omega^2(\tau))} \right]^{1/2} = \frac{1}{2 \sinh(\hbar\omega\beta/2)} \left[\frac{\det(-\partial_\tau^2 + \omega^2)}{\det(-\partial_\tau^2 + \Omega^2(\tau))} \right]^{1/2}. \end{aligned} \quad (7.340)$$

While the oscillator partition function can be calculated right-away in the continuum limit after forming ratios of eigenvalues, the second-quantized path integral depends sensitively on the choice $a_n^\dagger a_{n-1}$ in the action (7.310). It is easy to verify that the alternative slicings $a_{n+1}^\dagger a_n$ and $a_n^\dagger a_n$ would have led to the partition functions $[e^{\beta\hbar\omega} - 1]^{-1}$ and $[2 \sinh(\hbar\omega\beta/2)]^{-1}$, respectively. The different time slicings produce obviously the same physics as the corresponding time-ordered Hamiltonian operators $\hat{H} = \hat{T}\hat{a}^\dagger(t)\hat{a}(t')$ in which t' approaches t once from the right, once from the left, and once symmetrically from both sides.

It is easy to decide which of these mathematically possible approaches is the physically correct one. Classical mechanics is invariant under canonical transformations. So is Schrödinger theory. Certainly we want path integrals have the same invariance. Since the classical actions (7.300) and (7.301) arise from oscillator actions by the canonical transformation (7.296), the associated partition functions must be the same. This fixes the time-slicing of the harmonic oscillator to the symmetric one with the partition function (7.339), and the general result (7.340).

Another argument in favor of this symmetric ordering of the harmonic oscillator was given in Subsection 2.15.4. We shall see in Section 10.6 that in order to ensure invariance of path integrals under coordinate transformations, which is guaranteed in Schrödinger theory, path integrals should be defined by dimensional regularization. In this framework, the symmetric result (7.340) emerges.

It must be pointed out, however, that the correctness of the symmetric ordering for the oscillator action not true for arbitrary actions with an ordering ambiguity, as will be discussed in detail in Subsection (10.3.1). In fact, there exists to my knowledge no general rule how to translate the procedure of dimensional regularization into an operator-ordering language.

It is also worth noting that the symmetric result (7.339) gives rise to an important and poorly understood physical problem in many-body theory. Since *each* harmonic oscillator in the world has a ground-state energy ω implied by the limiting form (7.307), *each* momentum state of *each* particle field in the world contributes an energy $\hbar\omega/2$ to the vacuum energy. If all these $\hbar\omega/2$ are summed up, they produce a divergence in the cosmological constant, thus eliminating the existence of our universe. Somehow, the infinities of the free oscillators must be canceled by short-range interactions, and it may well be that we shall never possess a theory how this precisely happens. The present quantum field theories assume only interactions which are completely local. This is certainly a simplification, but it has the advantage that the effect of interactions can be calculated perturbatively order by order in the interaction strength. Moreover, if the local Lagrangian is suitably chosen, the infinities coming from the local interactions are such that our ignorance about their true short-distance behavior does not matter. The results depend only on the experimentally measured parameters, such as mass and coupling strength. Such local Lagrangians are called *renormalizable*. In a renormalizable theory, it is a fundamental rule that all infinities can be subtracted and absorbed in the initial parameters of the action to fit the experimentally observed parameters. The total

energy of all zero-point oscillations is one of these infinities which can be absorbed in the vacuum energy to fit the experimentally observed cosmological constant.

Some people want to ignore this subtraction freedom and get a finite sum over zero-point energies right at the free-field level. The only way to achieve this is by imagining the universe to contain for each Bose field a Fermi field which, as we shall see in Eq. (7.427), contributes a negative vacuum energy to the ground state. Some people have therefore proposed that the world is described by a theory with a broken *supersymmetry*, where an underlying action contains fermions and bosons completely symmetrically. Unfortunately, all elementary particle theories proposed so far possess completely unphysical particle spectra.

There are, however, important mathematical properties of supersymmetry with interesting applications. One of them plays a crucial role in the context of gauge fixing in nonabelian gauge theories, where a residual supersymmetry (the so-called BRST-symmetry) is important for renormalization. The other occurs in the context of disorder and will be presented in Section 18.16.

7.8 Coherent States

As long as we calculate the partition function of the harmonic oscillator in the variables $a^*(\tau)$ and $a(\tau)$, the path integrals do not differ from those of the harmonic oscillator (except for the possibly absent ground-state energy). The situation changes if we want to calculate the path integral (7.334) for specific initial and final values $a_a = a(\tau_a)$ and $a_b = a(\tau_b)$, implying also $a_a^* = a^*(\tau_a)$ and $a_b^* = a^*(\tau_b)$ by complex conjugation. In the definition of the canonical path integral in Section 2.1 we had to choose between measures (2.46) and (2.47), depending on which of the two completeness relations

$$\int dx |x\rangle\langle x| = 1, \quad \int \frac{dp}{2\pi} |p\rangle\langle p| = 1 \quad (7.341)$$

we wanted to insert into the factorized operator version of the Boltzmann factor $e^{-\beta\hat{H}}$ into products of $e^{-\epsilon\hat{H}}$. The time-sliced path integral (7.309), on the other hand, runs over $a^*(\tau)$ and $a(\tau)$ corresponding to an apparent completeness relation

$$\int dx \int \frac{dp}{2\pi} |xp\rangle\langle xp| = 1. \quad (7.342)$$

This resolution of the identity is at first sight surprising, since in a quantum-mechanical system *either* x *or* p can be specified, but not both. Thus we expect (7.342) to be structurally different from the completeness relations in (7.341). In fact, (7.342) may be called an *overcompleteness relation*.

In order to understand this, we form coherent states [49] similar to those used earlier in Eq. (3A.5):

$$|z\rangle \equiv e^{z\hat{a}^\dagger - z^*\hat{a}}|0\rangle, \quad \langle z| \equiv \langle 0|e^{-z\hat{a}^\dagger + z^*\hat{a}}. \quad (7.343)$$

The Baker-Campbell-Hausdorff formula (2.9) allows us to rewrite

$$e^{z\hat{a}^\dagger - z^*\hat{a}} = e^{z^*z[\hat{a}^\dagger, \hat{a}]/2} e^{z\hat{a}^\dagger} e^{-z^*\hat{a}} = e^{-z^*z/2} e^{z\hat{a}^\dagger} e^{-z^*\hat{a}}. \quad (7.344)$$

Since \hat{a} annihilates the vacuum state, we may expand

$$|z\rangle = e^{-z^*z/2} e^{z\hat{a}^\dagger} |0\rangle = e^{-z^*z/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!}} |n\rangle. \quad (7.345)$$

The states $|n\rangle$ and $\langle n|$ can be recovered from the coherent states $|z\rangle$ and $\langle z|$ by the operations:

$$|n\rangle = \left[|z\rangle e^{z^*z/2} \overleftarrow{\partial}_z^n \right]_{z=0} \frac{1}{\sqrt{n!}}, \quad \langle n| = \frac{1}{\sqrt{n!}} \left[\partial_{z^*}^n e^{z^*z/2} \langle z| \right]_{z=0}. \quad (7.346)$$

For an operator \hat{O} , the trace can be calculated from the integral over the diagonal elements

$$\text{tr } \hat{O} = \int \frac{dz^* dz}{\pi} \langle z| \hat{O} |z\rangle = \int \frac{dz^* dz}{\pi} e^{-z^*z} \sum_{m,n=0}^{\infty} \frac{z^{*m}}{\sqrt{m!}} \frac{z^n}{\sqrt{n!}} \langle m| \hat{O} |n\rangle. \quad (7.347)$$

Setting $z = re^{i\phi}$, this becomes

$$\text{tr } \hat{O} = \int dr^2 \left[\frac{d\phi}{2\pi} e^{-i(m-n)\phi} \right] e^{-r^2} \sum_{m,n=0}^{\infty} (r^2)^{(m+n)/2} \frac{1}{\sqrt{m!}} \frac{1}{\sqrt{n!}} \langle m| \hat{O} |n\rangle. \quad (7.348)$$

The integral over ϕ gives a Kronecker symbol $\delta_{m,n}$ and the integral over r^2 cancels the factorials, so that we remain with the diagonal sum

$$\text{tr } \hat{O} = \int dr^2 e^{-r^2} \sum_{n=0}^{\infty} (r^2)^n \frac{1}{n!} \langle n| \hat{O} |n\rangle = \sum_{n=0}^{\infty} \langle n| \hat{O} |n\rangle. \quad (7.349)$$

The sum on the right-hand side of (7.345) allows us to calculate immediately the scalar product of two such states:

$$\langle z_1 | z_2 \rangle = e^{-z_1^* z_1 / 2 - z_2^* z_2 / 2 + z_1^* z_2}. \quad (7.350)$$

The coherent states (7.343) with $z = (x + ip)/\sqrt{2}$ have precisely the property (7.342), i.e., we may identify:

$$|x p\rangle \equiv |z\rangle, \quad \text{where } z \equiv (x + ip)/\sqrt{2}. \quad (7.351)$$

Then (7.345) can be written as

$$|x p\rangle = e^{-(x^2 + p^2)/4} \sum_{n=0}^{\infty} \frac{(x + ip)^n}{\sqrt{2^n n!}} |0\rangle, \quad (7.352)$$

and

$$\int dx \frac{dp}{2\pi} |x p\rangle \langle x p| = \int dx \frac{dp}{2\pi} |x p\rangle \langle x p| e^{-(x^2+p^2)/2} \sum_{m,n=0}^{\infty} \frac{(x-ip)^m (x+ip)^n}{\sqrt{2^m m!} \sqrt{2^n n!}} |m\rangle \langle n|. \quad (7.353)$$

Setting $(x-ip)/\sqrt{2} \equiv r e^{i\phi}$, this can be rewritten as

$$\int dx \frac{dp}{2\pi} |x p\rangle \langle x p| = \int dr^2 \left[\frac{d\phi}{2\pi} e^{-i(m-n)\phi} \right] e^{-r^2} \sum_{m,n=0}^{\infty} \binom{m+n}{m} \frac{1}{\sqrt{m!}} \frac{1}{\sqrt{n!}} |m\rangle \langle n|. \quad (7.354)$$

The angular integration enforces $m = n$, and the integrals over r^2 cancel the factorials, as in (7.348), thus proving the resolution of the identity (7.342), which can also be written as

$$\int \frac{dz^* dz}{\pi} |z\rangle \langle z| = 1. \quad (7.355)$$

This resolution of the identity can now be inserted into a product decomposition of a Boltzmann operator

$$\langle z_b | e^{-\beta \hat{H}_\omega} | z_a \rangle = \langle z_b | e^{-\beta \hat{H}_\omega / (N+1)} e^{-\beta \hat{H}_\omega / (N+1)} \dots e^{-\beta \hat{H}_\omega / (N+1)} | z_a \rangle, \quad (7.356)$$

to arrive at a sliced path integral [compare (2.2)–(2.4)]

$$\langle z_b | e^{-\beta \hat{H}_\omega} | z_a \rangle = \prod_{n=1}^N \left[\int \frac{dz_n^* dz_n}{\pi} \right] \prod_{n=1}^{N+1} \langle z_n | e^{-\epsilon \hat{H}_\omega} | z_{n-1} \rangle, \quad z_0 = z_a, \quad z_{N+1} = z_b, \quad \epsilon \equiv \beta / (N+1). \quad (7.357)$$

We now calculate the matrix elements $\langle z_n | e^{-\epsilon \hat{H}_\omega} | z_{n-1} \rangle$ and find

$$\langle z_n | e^{-\epsilon \hat{H}_\omega} | z_{n-1} \rangle \approx \langle z_n | 1 - \epsilon \hat{H}_\omega | z_{n-1} \rangle = \langle z_n | z_{n-1} \rangle - \epsilon \langle z_n | \hat{H}_\omega | z_{n-1} \rangle. \quad (7.358)$$

Using (7.350) we find

$$\langle z_n | z_{n-1} \rangle = e^{-z_n^* z_n / 2 - z_{n-1}^* z_{n-1} / 2 + z_n^* z_{n-1}} = e^{-(1/2)[z_n^*(z_n - z_{n-1}) - (z_n^* - z_{n-1}^*)z_{n-1}]} \quad (7.359)$$

The matrix elements of the operator Hamiltonian (7.298) is easily found. The coherent states (7.345) are eigenstates of the annihilation operator \hat{a} with eigenvalue z :

$$\hat{a} | z \rangle = e^{-z^* z / 2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!}} \hat{a} | n \rangle = e^{-z^* z / 2} \sum_{n=1}^{\infty} \frac{z^n}{\sqrt{(n-1)!}} | n-1 \rangle = z | z \rangle. \quad (7.360)$$

Thus we find immediately

$$\langle z_n | \hat{H}_\omega | z_{n-1} \rangle = \hbar \omega \langle z_n | (\hat{a}^\dagger \hat{a} + \hat{a} \hat{a}^\dagger) | z_{n-1} \rangle = \hbar \omega \left(z_n^\dagger z_{n-1} + \frac{1}{2} \right). \quad (7.361)$$

Inserting this together with (7.359) into (7.358), we obtain for small ϵ the path integral

$$\langle z_b | e^{-\beta \hat{H}_\omega} | z_a \rangle = \prod_{n=1}^N \left[\int \frac{dz_n^* dz_n}{\pi} \right] e^{-\mathcal{A}_\omega^N [z^*, z] / \hbar}, \quad (7.362)$$

with the time-sliced action

$$\mathcal{A}_\omega^N[z^*, z] = \hbar\epsilon \sum_{n=1}^{N+1} \left\{ \frac{1}{2} [z_n^* \bar{\nabla} z_n - (\bar{\nabla} z_n^*) z_{n-1}] + \omega \left(z_n^* z_{n-1} + \frac{1}{2} \right) \right\}. \quad (7.363)$$

The gradient terms can be regrouped using formula (2.35), and rewriting its right-hand side as $p_{N+1}x_{N+1} - p_0x_0 + \sum_{n=1}^{N+1}(p_n - p_{n-1})x_{n-1}$. This leads to

$$\mathcal{A}_\omega^N[z^*, z] = \frac{\hbar}{2}(-z_b^* z_b + z_a^* z_a) + \hbar\epsilon \sum_{n=1}^{N+1} \left\{ z_n^* \bar{\nabla} z_n + \omega \left(z_n^* z_{n-1} + \frac{1}{2} \right) \right\}. \quad (7.364)$$

Except for the surface terms which disappear for periodic paths, this action agrees with the time-sliced Euclidean action (7.310), except for a trivial change of variables $a \rightarrow z$.

As a brief check of formula (7.362) we set $N = 0$ and find

$$\mathcal{A}_\omega^0[z^*, z] = \frac{\hbar}{2}(-z_b^* z_b + z_a^* z_a) + \hbar z_b^* (z_b - z_a) + \omega \left(z_b^* z_a + \frac{1}{2} \right), \quad (7.365)$$

and the short-time amplitude (7.364) becomes

$$\langle z_b | e^{-\epsilon \hat{H}_\omega} | z_a \rangle = \exp \left[-\frac{1}{2}(z_b^* z_b + z_a^* z_a) + z_b^* z_a - \epsilon \hbar \omega \left(z_b^* z_a + \frac{1}{2} \right) \right]. \quad (7.366)$$

Applying the recovery operations (7.346) we find

$$\langle 0 | e^{-\epsilon \hat{H}_\omega} | 0 \rangle = \left[e^{(z_b^* z_b + z_a^* z_a)/2} \langle z_b | e^{-\epsilon \hat{H}_\omega} | z_a \rangle \right]_{z^*=0, z=0} = e^{-\epsilon \hbar \omega / 2}, \quad (7.367)$$

$$\langle 1 | e^{-\epsilon \hat{H}_\omega} | 1 \rangle = \left\{ \partial_z \left[e^{(z_b^* z_b + z_a^* z_a)/2} \langle z_b | e^{-\epsilon \hat{H}_\omega} | z_a \rangle \right] \overset{\leftarrow}{\partial}_z^* \right\}_{z^*=0, z=0} = e^{-\epsilon 3 \hbar \omega / 2}, \quad (7.368)$$

$$\langle 0 | e^{-\epsilon \hat{H}_\omega} | 1 \rangle = \langle 1 | e^{-\epsilon \hat{H}_\omega} | 0 \rangle = 0. \quad (7.369)$$

Thus we have shown that for fixed ends, the path integral gives the amplitude for an initial coherent state $|z_a\rangle$ to go over to a final coherent state $|z_b\rangle$. The partition function (7.337) is obtained from this amplitude by forming the diagonal integral

$$Z_\omega = \int \frac{dz^* dz}{\pi} \langle z | e^{-\beta \hat{H}_\omega} | z \rangle. \quad (7.370)$$

7.9 Second-Quantized Fermi Fields

The existence of the periodic system of elements is based on the fact that electrons can occupy each orbital state only once (counting spin-up and -down states separately). Particles with this statistics are called *fermions*. In the above Hilbert space in which n -particle states at a point \mathbf{x} are represented by oscillator states $|n, \mathbf{x}\rangle$, this implies that the particle occupation number n can take only the values

$$\begin{aligned} n &= 0 \quad (\text{no electron}), \\ n &= 1 \quad (\text{one electron}). \end{aligned}$$

It is possible to construct such a restricted many-particle Hilbert space explicitly by subjecting the quantized fields $\hat{\psi}^\dagger(\mathbf{x})$, $\hat{\psi}(\mathbf{x})$ or their Fourier components $\hat{a}_{\mathbf{p}}^\dagger$, $\hat{a}_{\mathbf{p}}$ to *anticommutation relations*, instead of the commutation relations (7.282), i.e., by postulating

$$\begin{aligned} [\hat{\psi}(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)]_+ &= \delta_{\mathbf{x}\mathbf{x}'}, \\ [\hat{\psi}^\dagger(\mathbf{x}, t), \hat{\psi}^\dagger(\mathbf{x}', t)]_+ &= 0, \\ [\hat{\psi}(\mathbf{x}, t), \hat{\psi}(\mathbf{x}', t)]_+ &= 0, \end{aligned} \quad (7.371)$$

or for the Fourier components

$$\begin{aligned} [\hat{a}_{\mathbf{p}}(t), \hat{a}_{\mathbf{p}'}^\dagger(t)]_+ &= \delta_{\mathbf{p}\mathbf{p}'}, \\ [\hat{a}_{\mathbf{p}}^\dagger(t), \hat{a}_{\mathbf{p}'}^\dagger(t)]_+ &= 0, \\ [\hat{a}_{\mathbf{p}}(t), \hat{a}_{\mathbf{p}'}(t)]_+ &= 0. \end{aligned} \quad (7.372)$$

Here $[\hat{A}, \hat{B}]_+$ denotes the anticommutator of the operators \hat{A} and \hat{B}

$$[\hat{A}, \hat{B}]_+ \equiv \hat{A}\hat{B} + \hat{B}\hat{A}. \quad (7.373)$$

Apart from the anticommutation relations, the second-quantized description of Fermi fields is completely analogous to that of Bose fields in Section 7.6.

7.10 Fluctuating Fermi Fields

The question arises as to whether it is possible to find a path integral formulation which replaces the anticommuting operator structure. The answer is affirmative, but at the expense of a somewhat unconventional algebraic structure. The fluctuating paths can no longer be taken as *c*-numbers. Instead, they must be described by anticommuting variables.

7.10.1 Grassmann Variables

Mathematically, such objects are known under the name of *Grassmann variables*. They are defined by the algebraic property

$$\theta_1\theta_2 = -\theta_2\theta_1, \quad (7.374)$$

which makes them *nilpotent*:

$$\theta^2 = 0. \quad (7.375)$$

These variables have the curious consequence that an arbitrary function of them possesses only two Taylor coefficients, F_0 and F_1 ,

$$F(\theta) = F_0 + F_1\theta. \quad (7.376)$$

They are obtained from $F(\theta)$ as follows:

$$F_0 = F(0), \quad (7.377)$$

$$F_1 = F' \equiv \frac{\partial}{\partial \theta} F.$$

The existence of only two parameters in $F(\theta)$ is the reason why such functions naturally collect amplitudes of two local fermion states, F_0 for zero occupation, F_1 for a single occupation.

It is now possible to define integrals over functions of these variables in such a way that the previous path integral formalism remains applicable without a change in the notation, leading to the same results as the second-quantized theory with anticommutators. Recall that for ordinary real functions, integrals are linear functionals. We postulate this property also for integrals with Grassmann variables. Since an arbitrary function of a Grassmann variable $F(\theta)$ is at most linear in θ , its integral is completely determined by specifying only the two fundamental integrals $\int d\theta$ and $\int d\theta \theta$. The values which render the correct physics with a conventional path integral notation are

$$\int \frac{d\theta}{\sqrt{2\pi}} = 0, \quad (7.378)$$

$$\int \frac{d\theta}{\sqrt{2\pi}} \theta = 1. \quad (7.379)$$

Using the linearity property, an arbitrary function $F(\theta)$ is found to have the integral

$$\int \frac{d\theta}{\sqrt{2\pi}} F(\theta) = F_1 = F'. \quad (7.380)$$

Thus, integration of $F(\theta)$ coincides with differentiation. This must be remembered whenever Grassmann integration variables are to be changed: The integral is transformed with the *inverse* of the usual Jacobian. The obvious equation

$$\int \frac{d\theta}{\sqrt{2\pi}} F(c \cdot \theta) = c \cdot F' = c \cdot \int \frac{d\theta'}{\sqrt{2\pi}} F(\theta') \quad (7.381)$$

for any complex number c implies the relation

$$\int \frac{d\theta}{\sqrt{2\pi}} F(\theta'(\theta)) = \int \frac{d\theta'}{\sqrt{2\pi}} \left[\frac{d\theta}{d\theta'} \right]^{-1} F(\theta'). \quad (7.382)$$

For ordinary integration variables, the Jacobian $d\theta/d\theta'$ would appear without the power -1 .

When integrating over a product of two functions $F(\theta)$ and $G(\theta)$, the rule of integration by parts holds with the opposite sign with respect to that for ordinary integrals:

$$\int \frac{d\theta}{\sqrt{2\pi}} G(\theta) \frac{\partial}{\partial \theta} F(\theta) = \int \frac{d\theta}{\sqrt{2\pi}} \left[\frac{\partial}{\partial \theta} G(\theta) \right] F(\theta). \quad (7.383)$$

There exists a simple generalization of the Dirac δ -function to Grassmann variables. We shall define this function by the integral identity

$$\int \frac{d\theta'}{\sqrt{2\pi}} \delta(\theta - \theta') F(\theta') \equiv F(\theta). \quad (7.384)$$

Inserting the general form (7.376) for $F(\theta)$, we see that the function

$$\delta(\theta - \theta') = \theta' - \theta \quad (7.385)$$

satisfies (7.384). Note that the δ -function is a Grassmann variable and, in contrast to Dirac's δ -function, antisymmetric. Its derivative has the property

$$\delta'(\theta - \theta') \equiv \partial_{\theta} \delta(\theta - \theta') = -1. \quad (7.386)$$

It is interesting to see that δ' shares with Dirac's δ' the following property:

$$\int \frac{d\theta'}{\sqrt{2\pi}} \delta'(\theta - \theta') F(\theta') = -F'(\theta), \quad (7.387)$$

with the opposite sign of the Dirac case. This follows from the above rule of partial integration, or simpler, by inserting (7.386) and the explicit decomposition (7.376) for $F(\theta)$.

The integration may be extended to complex Grassmann variables which are combinations of two real Grassmann variables θ_1, θ_2 :

$$a^* = \frac{1}{\sqrt{2}}(\theta_1 - i\theta_2), \quad a = \frac{1}{\sqrt{2}}(\theta_1 + i\theta_2). \quad (7.388)$$

The measure of integration is defined by

$$\int \frac{da^* da}{\pi} \equiv \int \frac{d\theta_2 d\theta_1}{2\pi i} \equiv - \int \frac{da da^*}{\pi}. \quad (7.389)$$

Using (7.378) and (7.379) we see that the integration rules for complex Grassmann variables are

$$\int \frac{da^* da}{\pi} = 0, \quad \int \frac{da^* da}{\pi} a = 0, \quad \int \frac{da^* da}{\pi} a^* = 0, \quad (7.390)$$

$$\int \frac{da^* da}{\pi} a^* a = \int \frac{d\theta_2 d\theta_1}{2\pi i} i\theta_1 \theta_2 = 1. \quad (7.391)$$

Every function of $a^* a$ has at most two terms:

$$F(a^* a) = F_0 + F_1 a^* a. \quad (7.392)$$

In particular, the exponential $\exp\{-a^* A a\}$ with a complex number A has the Taylor series expansion

$$e^{-a^* A a} = 1 - a^* A a. \quad (7.393)$$

Thus we find the following formula for the Gaussian integral:

$$\int \frac{da^* da}{\pi} e^{-a^* A a} = A. \quad (7.394)$$

The integration rule (7.390) can be used directly to calculate the Grassmann version of the product of integrals (7.315). For a matrix A which can be diagonalized by a unitary transformation, we obtain directly

$$Z^f = \prod_n \left[\int \frac{da_n^* da_n}{\pi} \right] e^{i \sum_{n,n'} a_n^* A_{n,n'} a_{n'}} = \det A. \quad (7.395)$$

Remarkably, the fermion integration yields precisely the inverse of the boson result (7.315).

7.10.2 Fermionic Functional Determinant

Consider now the time-sliced path integral of the partition function written like (7.309) but with fermionic anticommuting variables. In order to find the same results as in operator quantum mechanics it is necessary to require the anticommuting Grassmann fields $a(\tau), a^*(\tau)$ to be *antiperiodic* on the interval $\tau \in (0, \hbar\beta)$, i.e.,

$$a(\hbar\beta) = -a(0), \quad (7.396)$$

or in the sliced form

$$a_{N+1} = -a_0. \quad (7.397)$$

Then the exponent of (7.395) has the same form as in (7.315), except that the matrix A of Eq. (7.318) is replaced by

$$A^f = \epsilon(1 - \epsilon\omega) \bar{\nabla}_\tau + \epsilon\omega = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 & 1 - \epsilon\omega \\ -1 + \epsilon\omega & 1 & 0 & \dots & 0 & 0 \\ 0 & -1 + \epsilon\omega & 1 & \dots & 0 & 0 \\ 0 & 0 & -1 + \epsilon\omega & \dots & 0 & 0 \\ \vdots & & & & & \vdots \\ 0 & 0 & 0 & \dots & -1 + \epsilon\omega & 1 \end{pmatrix}, \quad (7.398)$$

where the rows and columns are counted from 1 to $N + 1$. The element in the upper right corner is positive and thus has the opposite sign of the bosonic matrix in (7.318). This makes an important difference: While for $\omega = 0$ the bosonic matrix gave

$$\det(-\epsilon \bar{\nabla})_{\omega=0} = 0, \quad (7.399)$$

due to translational invariance in τ , we now have

$$\det(-\epsilon \bar{\nabla})_{\omega=0} = 2. \quad (7.400)$$

The determinant of the fermionic matrix (7.398) can be calculated by a repeated expansion along the first row [recall the calculations of the determinants (2.204) and (2.418)] and is found to be

$$\det_{N+1} A = 1 + (1 - \epsilon\omega)^{N+1}. \quad (7.401)$$

Hence we obtain the time-sliced fermion partition function

$$Z_\omega^{f,N} = \det_{N+1} [\epsilon(1 - \epsilon\omega)\bar{\nabla} + \epsilon\omega] = 1 + (1 - \epsilon\omega)^{N+1}. \quad (7.402)$$

As in the boson case, we introduce the auxiliary frequency

$$\bar{\omega}_e \equiv -\frac{1}{\epsilon} \log(1 - \epsilon\omega) \quad (7.403)$$

and write $Z_\omega^{f,N}$ in the form

$$Z_\omega^N = 1 + e^{-\beta\hbar\bar{\omega}_e}. \quad (7.404)$$

This partition function displays the typical property of Fermi particles. There are only two terms, one for the zero-particle and one for the one-particle state at a point. Their energies are 0 and $\hbar\bar{\omega}_e$, corresponding to the Hamiltonian operator

$$\hat{H}_\omega = \hbar\bar{\omega}_e \hat{N} = \hbar\bar{\omega}_e a^\dagger a. \quad (7.405)$$

In the continuum limit $\epsilon \rightarrow 0$, where $\bar{\omega}_e \rightarrow \omega$, the partition function Z_ω^N goes over into

$$Z_\omega = 1 + e^{-\beta\hbar\omega}. \quad (7.406)$$

Let us generalize also the fermion partition function to a system with a time-dependent frequency $\Omega(\tau)$, where it reads

$$Z_\omega^{f,N} = \prod_{n=0}^N \left[\int \frac{da_n^* da_n}{\pi} \right] \exp\left(-\frac{1}{\hbar} \mathcal{A}_\omega^N\right), \quad (7.407)$$

with the sliced action

$$\mathcal{A}_\omega^N = \hbar \sum_{n=1}^N [a_n^* (a_n - a_{n-1}) + \epsilon\Omega_n a_n^* a_{n-1}], \quad (7.408)$$

or, expressed in terms of the difference operator $\bar{\nabla}$,

$$\mathcal{A}_\omega^N = \hbar\epsilon \sum_{n=1}^N a_n^* [(1 - \epsilon\Omega_n)\bar{\nabla} + \Omega_n] a_n. \quad (7.409)$$

The result is

$$Z_\omega^{f,N} = \det_{N+1} [\epsilon(1 - \epsilon\Omega)\bar{\nabla} + \epsilon\omega] = 1 - \prod_{n=0}^N (1 - \epsilon\Omega_n). \quad (7.410)$$

As in the bosonic case, it is useful to introduce the auxiliary frequency

$$\bar{\Omega}_e \equiv -\frac{1}{(N+1)\epsilon} \sum_{n=0}^N \log(1 - \epsilon\Omega_n), \quad (7.411)$$

and write $Z_\omega^{f,N}$ in the form

$$Z_\omega^{f,N} = 1 + e^{-\beta\hbar\bar{\Omega}_e}. \quad (7.412)$$

If we attempt to write down a path integral formula for fermions directly in the continuum limit, we meet the same phenomenon as in the bosonic case. The difference operator (7.318) turns into the corresponding differential operator

$$(1 - \epsilon\omega)\bar{\nabla} + \omega \rightarrow \partial_\tau + \omega, \quad (7.413)$$

which now acts upon periodic complex functions $e^{-i\omega_m^f\tau}$ with the *odd* Matsubara frequencies

$$\omega_m^f = \pi(2m+1)k_B T/\hbar, \quad m = 0, \pm 1, \pm 2, \dots \quad (7.414)$$

The continuum partition function can be written as a path integral

$$\begin{aligned} Z_\omega^f &= \oint \frac{\mathcal{D}a^*\mathcal{D}a}{\pi} \exp \left[-\int_0^{\hbar\beta} d\tau (a^*\partial_\tau a + \omega a^*a) \right] \\ &= \mathcal{N}_\omega \det(\partial_\tau + \omega), \end{aligned} \quad (7.415)$$

with some normalization constant \mathcal{N}_ω determined by comparison with the time-sliced result. To calculate Z_ω^f , we take the eigenvalues of the operator $\partial_\tau + \omega$, which are now $-i\omega_m^f + \omega$, and evaluate the product of ratios

$$\prod_{m=-\infty}^{\infty} \frac{-i\omega_m^f + \omega}{-i\omega_m^f} = \cosh(\hbar\omega\beta/2). \quad (7.416)$$

This corresponds to the ratio of functional determinants

$$\frac{\det(\partial_\tau + \omega)}{\det(\partial_\tau)} = \cosh(\hbar\omega\beta/2). \quad (7.417)$$

In contrast to the boson case (7.336), no prime is necessary on the determinant of ∂_τ since there is no zero frequency in the product of eigenvalues (7.416). Setting $\mathcal{N}_\omega = 1/2\det(\partial_\tau)$, the ratio formula produces the correct partition function

$$Z_\omega^f = 2\cosh(\hbar\omega\beta/2). \quad (7.418)$$

Thus we may write the free-fermion path integral in the continuum form explicitly as follows:

$$\begin{aligned} Z_\omega^f &= \oint \frac{\mathcal{D}a^*\mathcal{D}a}{\pi} \exp \left[-\int_0^{\hbar\beta} d\tau (a^*\partial_\tau a + \omega a^*a) \right] = 2 \frac{\det(\partial_\tau + \omega)}{\det(\partial_\tau)} \\ &= 2 \cosh(\hbar\omega\beta/2). \end{aligned} \quad (7.419)$$

The determinant of the operator $\partial_\tau + \omega$ can again be replaced by

$$\det(\partial_\tau + \omega) = \det(-\partial_\tau + \omega) = \sqrt{\det(-\partial_\tau^2 + \omega^2)}. \quad (7.420)$$

As in the bosonic case, this Fermi analog of the harmonic oscillator partition function agrees with the results of dimensional regularization in Subsection 2.15.4 which will ensure invariance of path integrals under a change of variables, as will be seen in Section 10.6. The proper fermionic time-sliced partition function corresponding to the dimensional regularization in Subsection 2.15.4 is obtained from a fermionic version of the time-sliced oscillator partition function by evaluating

$$\begin{aligned} Z_\omega^{f,N} &= \left[\det_{N+1}(-\epsilon^2 \nabla \bar{\nabla} + \epsilon^2 \omega^2) \right]^{1/2} = \prod_{m=0}^N \left[\epsilon^2 \Omega_m^f \bar{\Omega}_m^f + \epsilon^2 \omega^2 \right]^{1/2} \\ &\equiv \prod_{m=0}^N \left[2(1 - \cos \omega_m^f \epsilon) + \epsilon^2 \omega^2 \right]^{1/2} = \prod_{m=0}^N \left[2 \sin^2 \frac{\epsilon \omega_m^f}{2} + \epsilon^2 \omega^2 \right]^{1/2}, \end{aligned} \quad (7.421)$$

with a product over the odd Matsubara frequencies ω_m^f . The result is

$$Z_\omega^{f,N} = 2 \cosh(\hbar \tilde{\omega}_e \beta), \quad (7.422)$$

with $\tilde{\omega}_e$ given by

$$\sinh(\tilde{\omega}_e/2) = \epsilon \omega/2. \quad (7.423)$$

This follows from the Fermi analogs of the product formulas (2.400), (2.402):⁷

$$\prod_{m=0}^{N/2-1} \left(1 - \frac{\sin^2 x}{\sin^2 \frac{(2m+1)\pi}{2(N+1)}} \right) = \frac{\cos(N+1)x}{\cos x}, \quad N = \text{even}, \quad (7.424)$$

$$\prod_{m=0}^{(N-1)/2} \left(1 - \frac{\sin^2 x}{\sin^2 \frac{(2m+1)\pi}{2(N+1)}} \right) = \cos(N+1)x, \quad N = \text{odd}. \quad (7.425)$$

For odd N , where all frequencies occur twice, we find from (7.425) that

$$\prod_{m=0}^N \left(1 - \frac{\sin^2 x}{\sin^2 \frac{(2m+1)\pi}{2(N+1)}} \right)^{1/2} = \cos(N+1)x, \quad (7.426)$$

and thus, with (7.423), directly (7.422). For even N , where the frequency with $m = N/2$ occurs only once, formula (7.424) gives once more the same answer, thus proving (7.426) for even *and* odd N .

There exists no real fermionic oscillator action since x^2 and \dot{x}^2 would vanish identically for fermions, due to the nilpotency (7.375) of Grassmann variables. The product of eigenvalues in Eq. (7.421) emerges naturally from a path integral in which the action (7.408) is replaced by a symmetrically sliced action.

⁷I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formulas 1.391.2, 1.391.4.

An important property of the partition function (7.418) of (7.422) is that the ground-state energy is *negative*:

$$E^{(0)} = -\frac{\hbar\omega}{2}. \quad (7.427)$$

As discussed at the end of Section 7.7, such a fermionic vacuum energy is required for each bosonic vacuum energy to avoid an infinite vacuum energy of the world, which would produce an infinite cosmological constant, whose experimentally observed value is extremely small.

7.10.3 Coherent States for Fermions

For the bosonic path integral (7.304) we have studied in Section 7.8, the case that the endpoint values $a_a = a(\tau_a)$ and $a_b = a(\tau_b)$ of the paths $a(\tau)$ are held fixed. The result was found to be the matrix element of the Boltzmann operator $e^{-\beta\hat{H}_\omega}$ between coherent states $|a\rangle = e^{-a^*a/2}e^{a\hat{a}^\dagger}|0\rangle$ [recall (7.345)]. There exists a similar interpretation for the fermion path integral (7.415) if we hold the endpoint values $a_a = a(\tau_a)$ and $a_b = a(\tau_b)$ of the Grassmann paths fixed. By analogy with Eq. (7.345) we introduce coherent states [50]

$$|\zeta\rangle \equiv e^{-\zeta^*\zeta/2}e^{a^\dagger\zeta}|0\rangle = e^{-\zeta^*\zeta/2}(|0\rangle - \zeta|1\rangle). \quad (7.428)$$

The corresponding adjoint states read

$$\langle\zeta| \equiv e^{-\zeta^*\zeta/2}\langle 0|e^{\zeta^*a} = e^{-\zeta^*\zeta/2}(\langle 0| + \zeta^*\langle 1|). \quad (7.429)$$

Note that for consistency of the formalism, the Grassmann elements ζ anticommute with the fermionic operators. The states $|0\rangle$ and $\langle 1|$ and their conjugates $\langle 0|$ and $|1\rangle$ can be recovered from the coherent states $|\zeta\rangle$ and $\langle\zeta|$ by the operations:

$$|n\rangle = \left[|\zeta\rangle e^{\zeta^*\zeta/2} \overleftarrow{\partial}_\zeta^n \right]_{\zeta=0} \frac{1}{\sqrt{n!}}, \quad \langle n| = \frac{1}{\sqrt{n!}} \left[\overrightarrow{\partial}_{\zeta^*}^n e^{\zeta^*\zeta/2} \langle\zeta| \right]_{\zeta=0}. \quad (7.430)$$

These formula simplify here to

$$|0\rangle = \left[|\zeta\rangle e^{\zeta^*\zeta/2} \right]_{\zeta=0}, \quad \langle 0| = \left[e^{\zeta^*\zeta/2} \langle\zeta| \right]_{\zeta=0}, \quad (7.431)$$

$$|1\rangle = \left[|\zeta\rangle e^{\zeta^*\zeta/2} \overleftarrow{\partial}_\zeta \right]_{\zeta=0}, \quad \langle 1| = \left[\overrightarrow{\partial}_{\zeta^*} e^{\zeta^*\zeta/2} \langle\zeta| \right]_{\zeta=0}. \quad (7.432)$$

For an operator \hat{O} , the trace can be calculated from the integral over the *antidiagonal* elements

$$\text{tr } \hat{O} = \int \frac{d\zeta^*d\zeta}{\pi} \langle -\zeta|\hat{O}|\zeta\rangle = \int \frac{d\zeta^*d\zeta}{\pi} e^{-\zeta^*\zeta} (\langle 0| - \zeta^*\langle 1|) \hat{O} (|0\rangle - \zeta|1\rangle). \quad (7.433)$$

Using the integration rules (7.390) and (7.391), this becomes

$$\text{tr } \hat{\mathcal{O}} = \langle 0 | \hat{\mathcal{O}} | 0 \rangle + \langle 1 | \hat{\mathcal{O}} | 1 \rangle. \quad (7.434)$$

The states $|\zeta\rangle$ form an overcomplete set in the one-fermion Hilbert space. The scalar products are [compare (7.350)]:

$$\begin{aligned} \langle \zeta_1 | \zeta_2 \rangle &= e^{-\zeta_1^* \zeta_1 / 2 - \zeta_2^* \zeta_2 / 2 + \zeta_1^* \zeta_2} \\ &= e^{-\zeta_1^* (\zeta_1 - \zeta_2) / 2 + (\zeta_1^* - \zeta_2^*) \zeta_2 / 2}. \end{aligned} \quad (7.435)$$

The resolution of the identity (7.355) is now found as follows [recall (7.390)]:

$$\begin{aligned} \int \frac{d\zeta^* d\zeta}{\pi} |\zeta\rangle \langle \zeta| &= \int \frac{d\zeta^* d\zeta}{\pi} e^{-\zeta^* \zeta} [|0\rangle \langle 0| - \zeta |1\rangle \langle 0| + \zeta^* |0\rangle \langle 1|] \\ &= \int \frac{d\zeta^* d\zeta}{\pi} [|0\rangle \langle 0| + |1\rangle \langle 0| \zeta + \zeta^* |0\rangle \langle 1| + \zeta \zeta^* (|0\rangle \langle 0| + |1\rangle \langle 0|)] = 1. \end{aligned} \quad (7.436)$$

We now insert this resolution of the identity into the product of Boltzmann factors

$$\langle \zeta_b | e^{-\beta \hat{H}_\omega} | \zeta_a \rangle = \langle \zeta_b | e^{-\epsilon \hat{H}_\omega} e^{-\epsilon \hat{H}_\omega} \dots e^{-\epsilon \hat{H}_\omega} | \zeta_a \rangle \quad (7.437)$$

where $\epsilon \equiv \beta / (N + 1)$, and obtain by analogy with (7.362) the time-sliced path integral

$$\langle \zeta_b | e^{-\beta \hat{H}_\omega} | \zeta_a \rangle = \prod_{n=1}^N \left[\int \frac{d\zeta_n^* d\zeta_n}{\pi} \right] e^{-\mathcal{A}_\epsilon[z^*, z] / \hbar}, \quad (7.438)$$

with the a time-sliced action similar to the bosonic one in (7.364):

$$\mathcal{A}_\omega^N[\zeta^*, \zeta] = \frac{\hbar}{2} (-\zeta_b^* \zeta_b + \zeta_a^* \zeta_a) + \hbar \epsilon \sum_{n=1}^{N+1} \left\{ \zeta_n^* \nabla \zeta_n + \omega \left(\zeta_n^* \zeta_{n-1} + \frac{1}{2} \right) \right\}. \quad (7.439)$$

Except for the surface term which disappears for antiperiodic paths, this agrees with the time-sliced Euclidean action (7.310), except for a trivial change of variables $a \rightarrow \zeta$.

We have shown that as in the Bose case the path integral with fixed ends gives the amplitude for an initial coherent state $|\zeta_a\rangle$ to go over to a final coherent state $|\zeta_b\rangle$. The fermion partition function (7.419) is obtained from this amplitude by forming the trace of the operator $e^{-\beta \hat{H}_\omega}$, which by formula (7.434) is given by the integral over the *antidiagonal* matrix elements

$$Z_\omega^f = \int \frac{d\zeta^* d\zeta}{\pi} \langle -\zeta | e^{-\beta \hat{H}_\omega} | \zeta \rangle. \quad (7.440)$$

The antidiagonal matrix elements lead to antiperiodic boundary conditions of the fermionic path integral.

7.11 Hilbert Space of Quantized Grassmann Variable

To understand the Hilbert space associated with a path integral over a Grassmann variable we recall that a path integral with zero Hamiltonian serves to define the Hilbert space via all its scalar products as shown in Eq. (2.18):

$$\langle x_b t_b | x_a t_a \rangle = \int \mathcal{D}x \int \frac{\mathcal{D}p}{2\pi\hbar} \exp \left[i \int dt p(t) \dot{x}(t) \right] = \langle x_b | x_a \rangle = \delta(x_b - x_a). \quad (7.441)$$

A momentum variable inside the integral corresponds to a derivative operator $\hat{p} \equiv -i\hbar\partial_x$ outside the amplitude, and this operator satisfies with $\hat{x} = x$ the canonical commutation relation $[\hat{p}, \hat{x}] = -i\hbar$ [see (2.19)].

By complete analogy with this it is possible to create the Hilbert space of spinor indices with the help of a path integral over anticommuting Grassmann variables. In order to understand the Hilbert space, we shall consider three different cases.

7.11.1 Single Real Grassmann Variable

First we consider the path integral of a real Grassmann field with zero Hamiltonian

$$\int \frac{\mathcal{D}\theta}{2\pi} \exp \left[\frac{i}{\hbar} \int dt \frac{i\hbar}{2} \theta(t) \dot{\theta}(t) \right]. \quad (7.442)$$

From the Lagrangian

$$\mathcal{L}(t) = \frac{i}{2} \hbar \theta(t) \dot{\theta}(t) \quad (7.443)$$

we obtain a canonical momentum

$$p_\theta = \frac{\partial \mathcal{L}}{\partial \dot{\theta}} = -\frac{i\hbar}{2} \theta. \quad (7.444)$$

Note the minus sign in (7.444) arising from the fact that the derivative with respect to $\dot{\theta}$ anticommutes with the variable θ on its left.

The canonical momentum is proportional to the dynamical variable. The system is therefore subject to a constraint

$$\chi = p_\theta + \frac{i\hbar}{2} \theta = 0. \quad (7.445)$$

In the Dirac classification this is a second-class constraint, in which case the quantization proceeds by forming the classical *Dirac brackets* rather than the Poisson brackets (1.20), and replacing them by $\pm i/\hbar$ times commutation or anticommutation relations, respectively. For n dynamical variables q_i and m constraints χ_p the Dirac brackets are defined by

$$\{A, B\}_D = \{A, B\} - \{A, \chi_p\} C^{pq} \{\chi_q, B\}, \quad (7.446)$$

where C^{pq} is the inverse of the matrix

$$C^{pq} = \{\chi_p, \chi_q\}. \quad (7.447)$$

For Grassmann variables p_i, q_i , the Poisson bracket (1.20) carries by definition an overall minus sign if A contains an odd product of Grassmann variables. Applying this rule to the present system we insert $A = p_\theta$ and $B = \theta$ into the Poisson bracket (1.20) we see that it vanishes. The constraint (7.445), on the other hand, satisfies

$$\{\chi, \chi\} = \left\{ p_\theta + \frac{i\hbar}{2}\theta, p_\theta + \frac{i\hbar}{2}\theta \right\} = -i\hbar\{p_\theta, \theta\} = -i\hbar. \quad (7.448)$$

Hence $C = -i\hbar$ with an inverse i/\hbar . The Dirac bracket is therefore

$$\{p_\theta, \theta\}_D = \{p_\theta, \theta\} - \frac{i}{\hbar}\{p_\theta, \chi\}\{\chi, \theta\} = 0 - \frac{-i}{\hbar} \left(\frac{i\hbar}{2} \right) (\hbar) = -\frac{\hbar}{2}. \quad (7.449)$$

With the substitution rule $\{A, B\}_D \rightarrow (-i/\hbar)[\hat{A}, \hat{B}]_+$, we therefore obtain the canonical equal-time anticommutation relation for this constrained system:

$$[\hat{p}(t), \hat{\theta}(t)]_+ = -\frac{i\hbar}{2}, \quad (7.450)$$

or, because of (7.444),

$$[\hat{\theta}(t), \hat{\theta}(t)]_+ = 1. \quad (7.451)$$

The proportionality of p_θ and θ has led to a factor 1/2 on the right-hand side with respect to the usual canonical anticommutation relation.

Let $\psi(\theta)$ be an arbitrary wave function of the general form (7.376):

$$\psi(\theta) = \psi_0 + \psi_1\theta. \quad (7.452)$$

The scalar product in the space of all wave functions is defined by the integral

$$\langle \psi' | \psi \rangle \equiv \int \frac{d\theta}{2\pi} \psi'^*(\theta) \psi(\theta) = \psi_0'^* \psi_1 + \psi_1'^* \psi_0. \quad (7.453)$$

In the so-defined Hilbert space, the operator $\hat{\theta}$ is diagonal, while the operator \hat{p} is given by the differential operator

$$\hat{p} = i\hbar\partial_\theta, \quad (7.454)$$

to satisfy (7.450).

The matrix elements of the operator \hat{p} are

$$\langle \psi' | \hat{p} | \psi \rangle \equiv \int \frac{d\theta}{2\pi} \psi'^*(\theta) i\hbar \frac{\partial}{\partial \theta} \psi(\theta) = i\hbar \psi_1'^* \psi_1. \quad (7.455)$$

By calculating

$$\langle \hat{p} \psi' | \psi \rangle \equiv \int \frac{d\theta}{2\pi} \left[i\hbar \frac{\partial}{\partial \theta} \psi'(\theta) \right]^* \psi(\theta) = -i\hbar \psi_1'^* \psi_1, \quad (7.456)$$

we see that the operator \hat{p} is anti-Hermitian, this being in accordance with the opposite sign in the rule (7.383) of integration by parts.

Let $|\theta\rangle$ be the local eigenstates of which the operator $\hat{\theta}$ is diagonal:

$$\hat{\theta}|\theta\rangle = \theta|\theta\rangle. \quad (7.457)$$

The operator $\hat{\theta}$ is Hermitian, such that

$$\langle\theta|\hat{\theta} = \langle\theta|\theta = \theta\langle\theta|. \quad (7.458)$$

The scalar products satisfy therefore the usual relation

$$(\theta' - \theta)\langle\theta'|\theta\rangle = 0. \quad (7.459)$$

On the other hand, the general expansion rule (7.376) tells us that the scalar product $S = \langle\theta'|\theta\rangle$ must be a linear combination of $S_0 + S_1\theta + S'_1\theta' + S_2\theta\theta'$. Inserting this into (7.459), we find

$$\langle\theta'|\theta\rangle = -\theta' + \theta + S_2\theta\theta', \quad (7.460)$$

where the proportionality constants S_0 and S_1 are fixed by the property

$$\langle\theta'|\theta\rangle = \int \frac{d\theta''}{2\pi} \langle\theta'|\theta''\rangle \langle\theta''|\theta\rangle. \quad (7.461)$$

The constant S_2 is an arbitrary real number. Recalling (7.385) we see that Eq. (7.460) implies that the scalar product $\langle\theta'|\theta\rangle$ is equal to a δ -function:

$$\langle\theta'|\theta\rangle = \delta(\theta - \theta'), \quad (7.462)$$

just as in ordinary quantum mechanics. Note the property

$$\langle\theta'|\theta\rangle^* = -\langle\theta|\theta'\rangle = \langle-\theta|-\theta'\rangle, \quad (7.463)$$

and the fact that since the scalar product $\langle\theta'|\theta\rangle$ is a Grassmann object, a Grassmann variable anticommutes with the scalar product. Having assumed in (7.458) that the Grassmann variable θ can be taken to the left of the bra-vector $\langle\theta|$, the ket-vector $|\theta\rangle$ must be treated like a Grassmann variable, i.e.,

$$\hat{\theta}|\theta\rangle = \theta|\theta\rangle = -|\theta\rangle\theta. \quad (7.464)$$

The momentum operator has the following matrix elements

$$\langle\theta'|\hat{p}|\theta\rangle = -i\hbar\partial_{\theta'}\langle\theta'|\theta\rangle = i\hbar. \quad (7.465)$$

Let $|p\rangle$ be an eigenstate of \hat{p} with eigenvalue ip , then its scalar product with $|\theta\rangle$ satisfies

$$\langle\theta|\hat{p}|p\rangle = \int \frac{d\theta'}{2\pi} \langle\theta|\hat{p}|\theta'\rangle \langle\theta'|p\rangle = i\hbar \int \frac{d\theta'}{2\pi} \langle\theta'|p\rangle = i\hbar\partial_{\theta'}\langle\theta'|p\rangle, \quad (7.466)$$

the last step following from the rule (7.380). Solving (7.466) we find

$$\langle \theta | p \rangle = e^{i\theta p/\hbar}, \quad (7.467)$$

the right-hand side being of course equal to $1 + i\theta p/\hbar$.

It is easy to find an orthonormal set of basis vectors in the space of wave functions (7.452):

$$\psi_+(\theta) \equiv \frac{1}{\sqrt{2}}(1 + \theta), \quad \psi_-(\theta) \equiv \frac{1}{\sqrt{2}}(1 - \theta). \quad (7.468)$$

We can easily check that these are orthogonal to each other and that they have the scalar products

$$\int \frac{d\theta}{2\pi} \psi_{\pm}^*(\theta) \psi_{\pm}(\theta) = \pm 1. \quad (7.469)$$

The Hilbert space contains states of negative norm which are referred to as *ghosts*. Because of the constraint, only half of the Hilbert space is physical. For more details on these problems see the literature on supersymmetric quantum mechanics.

7.11.2 Quantizing Harmonic Oscillator with Grassmann Variables

Let us now turn to the more important physical system containing two Grassmann variables θ_1 and θ_2 , combined to complex Grassmann variables (7.388). The Lagrangian is assumed to have the same form as that of an ordinary harmonic oscillator:

$$\mathcal{L}(t) = \hbar [a^*(t) i \partial_t a(t) - \omega a^*(t) a(t)]. \quad (7.470)$$

We may treat $a(t)$ and $a^*(t)$ as independent variables, such that there is no constraint in the system. The classical equation of motion

$$i\dot{a}(t) = \omega a(t) \quad (7.471)$$

is solved by

$$a(t) = e^{-i\omega t} a(0), \quad a^\dagger(t) = e^{-i\omega t} a^\dagger(0). \quad (7.472)$$

The canonical momentum reads

$$p_a(t) = \frac{\partial \mathcal{L}(t)}{\partial \dot{a}(t)} = -i\hbar a(t), \quad (7.473)$$

and the system is quantized by the equal-time anticommutation relation

$$[\hat{p}_a(t), \hat{a}(t)]_+ = -i\hbar, \quad (7.474)$$

or

$$[\hat{a}^\dagger(t), \hat{a}(t)]_+ = 1. \quad (7.475)$$

In addition we have

$$[\hat{a}(t), \hat{a}(t)]_+ = 0, \quad [\hat{a}^\dagger(t), \hat{a}^\dagger(t)]_+ = 0. \quad (7.476)$$

Due to these anticommutation relations, the time-independent number operator

$$\hat{N} \equiv a^\dagger(t)a(t) \quad (7.477)$$

satisfies the commutation relations

$$[\hat{N}, a^\dagger(t)] = a^\dagger(t), \quad [\hat{N}, a(t)] = -a(t). \quad (7.478)$$

We can solve the algebra defined by (7.475), (7.476), and (7.478) for any time, say $t = 0$, in the usual way, defining a ground state $|0\rangle$ by the condition

$$a|0\rangle = 0, \quad (7.479)$$

and an excited state $|1\rangle$ as

$$|1\rangle \equiv a^\dagger|0\rangle. \quad (7.480)$$

These are the only states, and the Hamiltonian operator $\hat{H} = \omega\hat{N}$ possesses the eigenvalues 0 and ω on them. Let $\psi(a)$ be wave functions in the representation where the operator a is diagonal. The canonically conjugate operator $\hat{p}_a = i\hbar\hat{a}^\dagger$ has then the form

$$\hat{p}_a \equiv -i\hbar\partial_a. \quad (7.481)$$

7.11.3 Spin System with Grassmann Variables

For the purpose of constructing path integrals of relativistic electrons later in Chapter 19 we discuss here another system with Grassmann variables.

Pauli Algebra

First we introduce three real Grassmann fields θ^i , $i = 1, 2, 3$, and consider the path integral

$$\prod_{i=1}^3 \left[\int \mathcal{D}\theta^i \right] \exp \left[\frac{i}{\hbar} \int dt \frac{i\hbar}{2} \theta^i(t) \dot{\theta}^i(t) \right]. \quad (7.482)$$

The equation of motion is

$$\dot{\theta}^i(t) = 0, \quad (7.483)$$

so that $\theta^i(t)$ are time independent variables. The three momentum operators lead now to the three-dimensional version of the equal-time anticommutation relation (7.451)

$$[\hat{\theta}^i(t), \hat{\theta}^j(t)]_+ = 2\delta^{ij}, \quad (7.484)$$

where the time arguments can be omitted due to (7.483). The algebra is solved with the help of the Pauli spin matrices (1.448). The solution of (7.484) is obviously

$$\langle B|\hat{\theta}^i|A\rangle = \sigma_{BA}^i, \quad A, B = 1, 2. \quad (7.485)$$

Let us now add in the exponent of the trivial path integral a Hamiltonian

$$H_B = -\mathbf{S} \cdot \mathbf{B}(t), \quad (7.486)$$

where

$$S^i \equiv -\frac{i}{4}\epsilon^{ijk}\theta^j\theta^k \quad (7.487)$$

plays the role of a spin vector. This can be verified by calculating the canonical commutation relations between the operators

$$[\hat{S}^i, \hat{S}^j] = i\epsilon_{ijk}\hat{S}^k, \quad (7.488)$$

and

$$[\hat{S}^i, \hat{\theta}^j] = i\epsilon_{ijk}\hat{\theta}^k. \quad (7.489)$$

Thus, the operator \hat{H} describes the coupling of a spin vector to a magnetic field $\mathbf{B}(t)$. Using the commutation relation (7.488), we find the Heisenberg equation (1.283) for the Grassmann variables:

$$\dot{\boldsymbol{\theta}} = \mathbf{B} \times \boldsymbol{\theta}, \quad (7.490)$$

which goes over into a similar equation for the spin vector:

$$\dot{\mathbf{S}} = \mathbf{B} \times \mathbf{S}. \quad (7.491)$$

The important observation is now that the path integral (7.482) with the magnetic Hamiltonian (7.486) with fixed ends $\theta_b^i = \theta^i(\tau_b)$ and $\theta_a^i = \theta^i(\tau_a)$ written as

$$\int_{\theta_a^i=\theta^i(\tau_a)}^{\theta_b^i=\theta^i(\tau_b)} \mathcal{D}^3\theta \exp \left[\frac{i}{\hbar} \int dt \left(\frac{i\hbar}{4}\theta^i\dot{\theta}^i + B^i \frac{i}{4}\epsilon^{ijk}\theta^j\theta^k \right) \right], \quad (7.492)$$

represents the matrix

$$\hat{T} \exp \left(-\frac{i}{\hbar} \int dt \mathbf{B}(t) \cdot \frac{\boldsymbol{\sigma}}{2} \right), \quad (7.493)$$

where \hat{T} is the time-ordering operator defined in Eq. (1.241). This operator is necessary for a time-dependent $\mathbf{B}(t)$ field since the matrices $\mathbf{B}(t)\boldsymbol{\sigma}/2$ for different times do not in general commute with each other.

The result may be expressed in a slightly different notation using the spin tensors

$$S^{ij} \equiv \epsilon^{ijk}S^k = \frac{1}{2i}\theta^i\theta^j, \quad (7.494)$$

whose matrix elements satisfy the rotation algebra

$$[\hat{S}^{ij}, \hat{S}^{kl}] = i \left(\delta^{ik}\hat{S}^{jl} - \delta^{il}\hat{S}^{jk} + \delta^{jl}\hat{S}^{ik} - \delta^{jk}\hat{S}^{il} \right), \quad (7.495)$$

and which have the matrix representation

$$\langle B | \hat{S}^{ij} | A \rangle = \frac{1}{2}\sigma_{BA}^{ij} \equiv \frac{1}{4i}[\sigma^i, \sigma^j]_{BA} = \epsilon^{ijk}\frac{\sigma^k}{2}. \quad (7.496)$$

Note the normalization

$$\sigma^{12} = \sigma^3. \quad (7.497)$$

Introducing the analogous magnetic field tensor

$$F_{ij} \equiv \epsilon^{ijk} B^k, \quad (7.498)$$

we can write the final result also in the tensorial form

$$\hat{T} \exp\left(-\frac{i}{4\hbar} \int dt F_{ij}(t) \sigma^{ij}\right) = \int_{\theta_a^i = \theta^i(\tau_a)}^{\theta_b^i = \theta^i(\tau_b)} \mathcal{D}^3 \theta \exp\left[\frac{i}{\hbar} \int dt \left(\frac{i\hbar}{4} \theta^i \dot{\theta}^i + \frac{i}{4} F_{ij} \theta^i \theta^j\right)\right]. \quad (7.499)$$

The trace of the left-hand side is, of course, given by the path integral over all antiperiodic Grassmann paths on the right-hand side.

Whenever we encounter time-ordered exponentials of integrals over matrices, these can be transformed into a fluctuating path integral over Grassmann variables. If we want to find individual matrix elements, we have to make use of suitably extended recovery formulas (7.431) and (7.432).

For a constant \mathbf{B} -field, the time ordering operator can be ignored and the exponential (7.493) can immediately be written down explicitly [see Eq. (1A.2)].

In the applications to come, we need only the trace of the matrix (7.493). According to Eq. (7.440), this is found from the integral over (7.492) with $\theta_b^i = -\theta_a^i$, which means performing the integral over all antiperiodic Grassmann paths $\theta^i(\tau)$. For a constant \mathbf{B} -field, the trace of the operator (7.493) is immediately extracted from Eq. (1A.2):

$$\oint \mathcal{D}^3 \theta \exp\left[\frac{i}{\hbar} \int dt \left(\frac{i\hbar}{4} \theta^i \dot{\theta}^i + B^i \frac{i}{4} \epsilon^{ijk} \theta^j \theta^k\right)\right] = 2 \cos[|\mathbf{B}|(t_b - t_a)/2\hbar]. \quad (7.500)$$

This result can also be derived directly from the path integral over the Grassmann variables θ^i , which yields the square root of the functional determinant

$$2 \text{Det}^{1/2} \left[\delta_{ij} i \partial_t + \frac{i}{\hbar} F_{ij}(x(t)) \right]. \quad (7.501)$$

Here the normalization factor 2 is determined by the path integral with $F_{ij} = 0$, which simply counts the two possible states of the matrix representation (7.496), as in the trace of the left-hand side of (7.499) for $F_{ij} = 0$. Thus

$$\int \mathcal{D}^3 \theta \exp\left\{\frac{i}{\hbar} \int dt \left[\frac{i\hbar}{4} \theta^i \dot{\theta}^i\right]\right\} = 2. \quad (7.502)$$

This normalization factor agrees with Eqs. (7.415) and (7.418), where the path integral of single complex fermion field gives the same factor 2 for $\omega = 0$

For a constant \mathbf{B} -field in the z -direction, and antiperiodic boundary conditions in the time interval (t_b, t_a) , the matrix in the brackets has the form

$$\begin{pmatrix} \omega_m^f & iB & 0 \\ -iB & \omega_m^f & 0 \\ 0 & 0 & \omega_m^f \end{pmatrix}, \quad \omega_m^f = \frac{\pi(2m+1)}{t_b - t_a}, \quad (7.503)$$

where ω_m^f are the real-time versions of the odd Matsubara frequencies (7.415). The functional determinant (7.501) is then obtained from the product [compare (7.416)]

$$\text{Det}^{1/2} \left[\delta_{ij} i\partial_t + \frac{i}{\hbar} F_{ij} \right] = \left[\prod_{m=-\infty}^{\infty} |\omega_m| (\omega_m^2 - B^2/\hbar^2) \right]^{1/2} = \cos[B(t_b - t_a)/2\hbar]. \quad (7.504)$$

The determinant in the second expression is an ordinary determinant of the 4×4 -dimensional matrix in the argument of the cosine, to be calculated from its Taylor expansion.

Dirac Algebra

There exists a similar path integral suitable for describing relativistic spin systems. If we introduce four Grassmann variables θ^μ , $\mu = 0, 1, 2, 3$, the path integral

$$\prod_{\mu=0}^3 \left[\int \mathcal{D}\theta^\mu \right] \exp \left\{ \frac{i}{\hbar} \int dt \left[-\frac{i\hbar}{4} \theta_\mu(t) \dot{\theta}^\mu(t) \right] \right\}, \quad (7.505)$$

leads to an equation of motion

$$\dot{\theta}^\mu(t) = 0, \quad (7.506)$$

and an operator algebra at equal times

$$\{\hat{\theta}^\mu(t), \hat{\theta}^\nu(t)\} = 2g^{\mu\nu}, \quad (7.507)$$

where $g_{\mu\nu}$ is the metric in Minkowski space

$$g^{\mu\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}. \quad (7.508)$$

The time argument in (7.507) can again be dropped due to (7.506). The algebra (7.507) is solved by the matrix elements [recall (7.485)]

$$\langle \beta | \hat{\theta}^\mu(t) | \alpha \rangle = (\gamma^\mu)_{\beta\alpha}, \quad \beta, \alpha = 1, 2, 3, 4, \quad (7.509)$$

where γ^μ, γ_5 are composed of 2×2 -matrices 0, 1, and σ^i as follows:

$$\gamma^0 \equiv \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad \gamma^i \equiv \begin{pmatrix} 0 & \sigma^i \\ -\sigma^i & 0 \end{pmatrix}, \quad \gamma_5 \equiv i\gamma^0\gamma^1\gamma^2\gamma^3 = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \equiv \gamma^5. \quad (7.510)$$

One may also introduce an additional Grassmann variable θ_5 such that the path integral

$$\prod_{\mu=0}^3 \left[\int \mathcal{D}\theta_5 \right] \exp \left[\frac{i}{\hbar} \int dt \frac{i\hbar}{4} \theta_5(t) \dot{\theta}_5(t) \right], \quad (7.511)$$

produces the matrix elements of $\gamma_5(t)$:

$$\langle \beta | \hat{\theta}_5(t) | \alpha \rangle = (\gamma_5)_{\beta\alpha}, \quad \beta, \alpha = 1, 2, 3, 4. \quad (7.512)$$

The Grassmann variables θ^μ and θ_5 anticommute with each other, and so do the matrices $\gamma_5\gamma^\mu$ and γ_5 .

In terms of the Grassmann variables θ^μ it is possible to write down a four-dimensional version of the time-ordered 2×2 matrix integral (7.499) as a path integral without time ordering:

$$\hat{T} \exp \left(-\frac{i}{2\hbar} \int dt F_{\mu\nu} \Sigma^{\mu\nu} \right) = \int \mathcal{D}^4\theta \exp \left\{ \frac{i}{\hbar} \int dt \left[-\frac{i\hbar}{2} \theta_\mu \dot{\theta}^\mu + \frac{i}{4} F_{\mu\nu} \theta^\mu \theta^\nu \right] \right\}, \quad (7.513)$$

where $\Sigma^{\mu\nu}$ is the Minkowski space generalization of the spin tensor matrix $\sigma^{ij}/2$ in (7.496):

$$\Sigma^{\mu\nu} \equiv \frac{i}{4} [\gamma^\mu, \gamma^\nu] = -\Sigma^{\nu\mu}. \quad (7.514)$$

As a check we use (7.510) and find

$$\Sigma^{12} = \frac{1}{2} \begin{pmatrix} \sigma^{12} & 0 \\ 0 & \sigma^{12} \end{pmatrix} = \frac{1}{2} \begin{pmatrix} \sigma^3 & 0 \\ 0 & \sigma^3 \end{pmatrix}, \quad (7.515)$$

in agreement with (7.497).

As remarked before, we shall need in the applications to come only the trace of the matrix (7.493), which is found, according to Eq. (7.440), from the integral over (7.492) with $\theta_b^i = -\theta_a^i$, i.e., by performing the integral over all antiperiodic Grassmann paths $\theta^i(\tau)$. If we want to find individual matrix elements, we have to make use of suitably extended recovery formulas (7.431) and (7.432).

The path integral over all antiperiodic paths for $F_{\mu\nu} = 0$ fixes the normalization. For zero fields, the trace of the left-hand side of (7.513) is equal to 4, so that we have

$$\int \mathcal{D}^4\theta \exp \left\{ \frac{i}{\hbar} \int dt \left[-\frac{i\hbar}{4} \theta_\mu \dot{\theta}^\mu \right] \right\} = 4. \quad (7.516)$$

This normalization factor agrees with Eqs. (7.415) and (7.418), where we found the path integral of single complex fermion field to carry a normalization factor 2. For four real fields this corresponds to a factor 4.

In the presence of a nonzero field tensor, the result of the path integral (7.513) is therefore

$$\int \mathcal{D}^4\theta e^{(i/4\hbar) \int dt \{ -i\hbar \theta_\mu \dot{\theta}^\mu + i F_{\mu\nu} \theta^\mu \theta^\nu \}} = 4 \text{Det}^{1/2} \left[-g_{\mu\nu} i\partial_t + \frac{i}{\hbar} F_{\mu\nu}(x(t)) \right]. \quad (7.517)$$

In the presence of a constant electric and a constant magnetic field in the z -direction, then $F_{03} = E$, and

$$F_{\mu\nu} = \begin{pmatrix} 0 & 0 & 0 & E \\ 0 & 0 & -B & 0 \\ 0 & B & 0 & 0 \\ E & 0 & 0 & 0 \end{pmatrix}. \quad (7.518)$$

Thus we find

$$e^{F_{\mu\nu}t} = \begin{pmatrix} \cosh Et & 0 & 0 & \sinh Et \\ 0 & \cos Bt & -\sin Bt & 0 \\ 0 & \sin Bt & \cos Bt & 0 \\ \sinh Et & 0 & 0 & \cosh Et \end{pmatrix}, \quad (7.519)$$

so that

$$\text{Det} \left(-g_{\mu\nu} i\partial_t + \frac{i}{\hbar} F_{\mu\nu} \right) = \det \cos \left(F_{\mu\nu} \frac{t_b - t_a}{2\hbar} \right) = \cos^2 \left(B \frac{t_b - t_a}{2\hbar} \right) \cosh^2 \left(E \frac{t_b - t_a}{2\hbar} \right). \quad (7.520)$$

Constant Electric and Magnetic Field in any Direction

If there are both constant electric and magnetic fields in any direction, the calculation can be reduced to the parallel case by a simple Lorentz transformation. It is always possible to find a Lorentz frame in which the fields become parallel. This special frame will be called *center-of-fields* frame, and the transformed fields in this frame will be denoted by \mathbf{B}_{CF} and \mathbf{E}_{CF} . The transformation has the form

$$\mathbf{E}_{\text{CF}} = \gamma \left(\mathbf{E} + \frac{\mathbf{v}}{c} \times \mathbf{B} \right) - \frac{\gamma^2}{\gamma + 1} \frac{\mathbf{v}}{c} \left(\frac{\mathbf{v}}{c} \cdot \mathbf{E} \right), \quad (7.521)$$

$$\mathbf{B}_{\text{CF}} = \gamma \left(\mathbf{B} - \frac{\mathbf{v}}{c} \times \mathbf{E} \right) - \frac{\gamma^2}{\gamma + 1} \frac{\mathbf{v}}{c} \left(\frac{\mathbf{v}}{c} \cdot \mathbf{B} \right), \quad (7.522)$$

with a velocity of the transformation determined by

$$\frac{\mathbf{v}/c}{1 + (|\mathbf{v}|/c)^2} = \frac{\mathbf{E} \times \mathbf{B}}{|\mathbf{E}|^2 + |\mathbf{B}|^2}, \quad (7.523)$$

and $\gamma \equiv [1 - (|\mathbf{v}|/c)^2]^{-1/2}$. The fields $|\mathbf{E}_{\text{CF}}| \equiv \mathcal{E}$ and $|\mathbf{B}_{\text{CF}}| \equiv \mathcal{B}$ are, of course, Lorentz-invariant quantities which can be expressed in terms of the two quadratic Lorentz invariants of the electromagnetic field: the scalar S and the pseudoscalar P defined by

$$S \equiv -\frac{1}{4} F_{\mu\nu} F^{\mu\nu} = \frac{1}{2} (\mathbf{E}^2 - \mathbf{B}^2) = \frac{1}{2} (\mathcal{E}^2 - \mathcal{B}^2), \quad P \equiv -\frac{1}{4} F_{\mu\nu} \tilde{F}^{\mu\nu} = \mathbf{E} \cdot \mathbf{B} = \mathcal{E} \mathcal{B}. \quad (7.524)$$

Solving these equation yields

$$\left\{ \begin{array}{l} \mathcal{E} \\ \mathcal{B} \end{array} \right\} \equiv \sqrt{\sqrt{S^2 + P^2} \pm S} = \frac{1}{\sqrt{2}} \sqrt{\sqrt{(\mathbf{E}^2 - \mathbf{B}^2)^2 + 4(\mathbf{E} \cdot \mathbf{B})^2} \pm (\mathbf{E}^2 - \mathbf{B}^2)}. \quad (7.525)$$

After these transformations, the result (7.520) remains valid for any constant field directions if we exchange $E \rightarrow \mathcal{E}$, $B \rightarrow \mathcal{B}$.

Relation between Harmonic Oscillator, Pauli and Dirac Algebra

There exists a simple relation between the path integrals of the previous three paragraphs. We simply observe that the combinations

$$\hat{a}^\dagger = \frac{1}{2}(\sigma^1 + i\sigma^2) = \frac{1}{2}\sigma^+ = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \hat{a} = \frac{1}{2}(\sigma^1 - i\sigma^2) = \frac{1}{2}\sigma^- = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad (7.526)$$

satisfy the anticommutation rules

$$[\hat{a}, \hat{a}^\dagger]_+ = 1, \quad [\hat{a}^\dagger, \hat{a}^\dagger]_+ = 1, \quad [\hat{a}, \hat{a}]_+ = 0. \quad (7.527)$$

The vacuum state annihilated by a is the spin-down spinor, and the one-particle state is the spin-up spinor:

$$|0\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad |1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}. \quad (7.528)$$

A similar construction can be found for the Dirac algebra. There are now two types of creation and annihilation operators

$$\hat{a}^\dagger = \frac{1}{2}(\gamma^1 + i\gamma^2) = \frac{1}{2} \begin{pmatrix} 0 & \sigma^+ \\ -\sigma^+ & 0 \end{pmatrix}, \quad \hat{a} = \frac{1}{2}(-\gamma^1 + i\gamma^2) = \frac{1}{2} \begin{pmatrix} 0 & -\sigma^- \\ \sigma^- & 0 \end{pmatrix}, \quad (7.529)$$

and

$$\hat{b}^\dagger = \frac{1}{2}(\gamma^0 + \gamma^3) = \frac{1}{2} \begin{pmatrix} 0 & i\sigma^2\sigma^+ \\ -i\sigma^2\sigma^+ & 0 \end{pmatrix}, \quad \hat{b} = \frac{1}{2}(\gamma^1 - \gamma^3) = \frac{1}{2} \begin{pmatrix} 0 & i\sigma^2\sigma^- \\ -i\sigma^2\sigma^- & 0 \end{pmatrix}. \quad (7.530)$$

The states $|n_a, a_b\rangle$ with n_a quanta a and n_b quanta b are the following:

$$|0, 0\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ 1 \\ 0 \\ 1 \end{pmatrix}, \quad |1, 0\rangle = a^\dagger|0, 0\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ -1 \\ 0 \end{pmatrix}, \quad (7.531)$$

$$|0, 1\rangle = b^\dagger|0, 0\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ -1 \\ 0 \\ 1 \end{pmatrix}, \quad |1, 1\rangle = a^\dagger b^\dagger|0, 0\rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \end{pmatrix}. \quad (7.532)$$

From these relations we can easily deduce the proper recovery formulas generalizing (7.431) and (7.432).

7.12 External Sources in a^* , a -Path Integral

In Chapter 3, the path integral of the harmonic oscillator was solved in the presence of an arbitrary external current $j(\tau)$. This yielded the generating functional $Z[j]$ for the calculation of all correlation functions of $x(\tau)$. In the present context we are interested in the generating functional of correlations of $a(\tau)$ and $a^*(\tau)$. Thus we also need the path integrals quadratic in $a(\tau)$ and $a^*(\tau)$ coupled to external currents. Consider the Euclidean action

$$\mathcal{A}[a^*, a] + \mathcal{A}^{\text{source}} = \hbar \int_0^{\hbar\beta} d\tau [a^*(\tau) \partial_\tau a(\tau) + \omega a^* a(\tau) - (\eta^*(\tau) a(\tau) + \text{c.c.})], \quad (7.533)$$

with periodic boundary conditions for $a(\tau)$ and $a^*(\tau)$. For simplicity, we shall use the continuum formulation of the partition function, so that our results will correspond to the harmonic oscillator time slicing, with the energies $E_n = (n + 1/2)\hbar\omega$. There is no problem in going over to the second-quantized formulation with the energies $E_n = n\hbar\omega$. The partition function is given by the path integral

$$Z_\omega[\eta^*, \eta] = \oint \frac{\mathcal{D}a^* \mathcal{D}a}{\pi} \exp \left\{ -\frac{1}{\hbar} (\mathcal{A}[a^*, a] + \mathcal{A}^{\text{source}}) \right\}. \quad (7.534)$$

As in Chapter 3, we define the functional matrix between $a^*(\tau)$, $a(\tau')$ as

$$D_{\omega,e}(\tau, \tau') \equiv (\partial_\tau + \omega) \delta(\tau - \tau'), \quad \tau, \tau' \in (0, \hbar\beta). \quad (7.535)$$

The inverse is the Euclidean Green function

$$G_{\omega,e}^{\text{p}}(\tau, \tau') = D_{\omega,e}^{-1}(\tau, \tau'), \quad (7.536)$$

satisfying the periodic boundary condition. We now complete the square and rewrite the action (7.533), using the shifted fields

$$a'(\tau) = a(\tau) - \int_0^{\hbar\beta} d\tau' G_{\omega,e}^{\text{p}}(\tau, \tau') \eta(\tau') \quad (7.537)$$

as

$$\mathcal{A}_e = \hbar \int_0^{\hbar\beta} d\tau \int_0^{\hbar\beta} d\tau' [a'^*(\tau) D_{\omega,e}(\tau, \tau') a'(\tau') - \eta^*(\tau) G_{\omega,e}^{\text{p}}(\tau, \tau') \eta(\tau')]. \quad (7.538)$$

On an infinite β -interval the Green function can easily be written down in terms of the Heaviside function (1.313):

$$G_{\omega,e}(\tau, \tau') = G_{\omega,e}(\tau - \tau') = e^{-\omega(\tau - \tau')} \Theta(\tau - \tau'). \quad (7.539)$$

As we have learned in Section 3.3, the periodic Green function is obtained from this by forming a periodic sum

$$G_{\omega,e}^{\text{p}}(\tau, \tau') = G_{\omega,e}^{\text{p}}(\tau - \tau') = \sum_{n=-\infty}^{\infty} e^{-\omega(\tau - \tau' - n\hbar\beta)} \Theta(\tau - \tau' - n\hbar\beta), \quad (7.540)$$

which is equal to

$$G_{\omega,e}^p(\tau) = \frac{e^{-\omega(\tau-\hbar\beta/2)}}{2\sinh(\omega\hbar\beta/2)} = (1+n_\omega^b)e^{-\omega\tau}, \quad (7.541)$$

where n_ω is the Bose-Einstein distribution function

$$n_\omega = \frac{1}{e^{\beta\hbar\omega} - 1} \quad (7.542)$$

[compare (3.92) and (3.93)].

The same considerations hold for anticommuting variables with antiperiodic boundary conditions, in which case we find once more the action (7.538) with the

ref(3.112) antiperiodic Green function [compare (3.112)]
lab(3.75)
est(3.74)

$$G_{\omega,e}^a(\tau) = \frac{e^{-\omega(\tau-\hbar\beta/2)}}{2\cosh(\omega\hbar\beta/2)} = (1-n_\omega^f)e^{-\omega\tau}, \quad (7.543)$$

ref(3.111) where n_ω is the Fermi-Dirac distribution function [see (3.111)]:

lab(3.74)
est(3.73)

$$n_\omega^f = \frac{1}{e^{\beta\hbar\omega} + 1}. \quad (7.544)$$

In either case, we may decompose the currents in (7.538) into real and imaginary parts j and k via

$$\begin{aligned} \eta &= \sqrt{\omega/2M\hbar}(j - i\omega Mk), \\ \eta^* &= \sqrt{\omega/2M\hbar}(j + i\omega Mk), \end{aligned} \quad (7.545)$$

and write the source part of the original action (7.533) in the form

$$\mathcal{A}^{\text{source}} = \hbar \int_0^{\hbar\beta} d\tau (a^* \eta + \eta^* a) = \int_0^{\hbar\beta} d\tau (jx + kp). \quad (7.546)$$

Hence, the real current $\eta = \eta^* = \sqrt{\omega/2M\hbar} j$ corresponds to the earlier source term (3.2). Inserting this current into the action (7.538), it yields the quadratic source

ref(3.2)
lab(3.2)
est(3.2)

$$\mathcal{A}_e^s = -\frac{1}{2M\omega} \int_0^{\hbar\beta} d\tau \int_0^\tau d\tau' \frac{e^{-\omega(\tau-\tau')}}{1 - e^{-\beta\hbar\omega}} j(\tau)j(\tau'). \quad (7.547)$$

This can also be rewritten as

$$\mathcal{A}_e^s = -\frac{1}{2M\omega} \sum_{n=0}^{\infty} \int_0^{\hbar\omega} d\tau \int_0^\tau d\tau' e^{-\omega(\tau-\tau'+n\hbar\beta)} j(\tau)j(\tau'), \quad (7.548)$$

which becomes for a current periodic in $\hbar\beta$:

$$\mathcal{A}_e^s = -\frac{1}{2M\omega} \int_0^{\hbar\omega} d\tau \int_{-\infty}^\tau d\tau' e^{-\omega(\tau-\tau')} j(\tau)j(\tau'). \quad (7.549)$$

Interchanging τ and τ' , this is also equal to

$$\mathcal{A}_e^s = -\frac{1}{4M\omega} \int_0^{\hbar\omega} d\tau \int_{-\infty}^\infty d\tau' e^{-\omega|\tau-\tau'|} j(\tau)j(\tau'), \quad (7.550)$$

in agreement with (3.279).

7.13 Generalization to Pair Terms

There exists an important generalization of these considerations to the case of the quadratic frequency term $\hbar \int d\tau \Omega^2(\tau) a^*(\tau) a(\tau)$ being extended to the more general quadratic form

$$\hbar \int d\tau \left[\Omega^2(\tau) a^*(\tau) a(\tau) + \frac{1}{2} \Delta^*(\tau) a^2(\tau) + \frac{1}{2} \Delta(\tau) a^{*2}(\tau) \right]. \quad (7.551)$$

The additional off-diagonal terms in a^* , a are called *pair terms*. They play an important role in the theory of superconductivity. The basic physical mechanism for this phenomenon will be explained in Section 17.10. Here we just mention that the lattice vibrations give rise to the formation of bound states between pairs of electrons, called *Cooper pairs*. By certain manipulations of the path integral of the electron field in the second-quantized interpretation, it is possible to introduce a complex pair field $\Delta_{\mathbf{x}}(t)$ at each space point which is coupled to the electron field in an action of the type (7.551). The partition function to be studied is then of the generic form

$$Z = \oint \frac{\mathcal{D}a^* \mathcal{D}a}{\pi} \exp \left[- \int_0^{\hbar\beta} d\tau (a^* \partial_\tau a + \Omega^2 a^* a + \frac{1}{2} \Delta^* a^2 + \frac{1}{2} \Delta a^{*2}) \right]. \quad (7.552)$$

It is easy to calculate this partition function on the basis of the previous formulas. To this end we rewrite the action in the matrix form, using the field doublets

$$f(\tau) \equiv \begin{pmatrix} a(\tau) \\ a^*(\tau) \end{pmatrix}, \quad (7.553)$$

as

$$\mathcal{A}_e = \frac{\hbar}{2} \int_0^{\hbar\beta} d\tau f^{*T}(\tau) \begin{pmatrix} \partial_\tau + \Omega(\tau) & \Delta(\tau) \\ \Delta^*(\tau) & \mp(\partial_\tau \pm \Omega(\tau)) \end{pmatrix} f(\tau), \quad (7.554)$$

where the derivative terms require a partial integration to obtain this form. The partition function can be written as

$$Z = \int \frac{\mathcal{D}f^* \mathcal{D}f}{\pi} e^{-\frac{1}{2} f^* M f}, \quad (7.555)$$

with the matrix

$$M = \begin{pmatrix} \partial_\tau + \Omega(\tau) & \Delta(\tau) \\ \Delta^*(\tau) & \mp(\partial_\tau \pm \Omega(\tau)) \end{pmatrix}. \quad (7.556)$$

The fields f^* and f are not independent of each other, since

$$f^* = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} f. \quad (7.557)$$

Thus, there are only half as many independent integrations as for a usual complex field. This has the consequence that the functional integration in (7.555) gives only the square root of the determinant of M ,

$$Z = \mathcal{N}^{b,f} \det \begin{pmatrix} \partial_\tau + \Omega(\tau) & \Delta(\tau) \\ \Delta^*(\tau) & \mp(\partial_\tau + \Omega(\tau)) \end{pmatrix}^{\mp 1/2}, \quad (7.558)$$

with the normalization factors $\mathcal{N}^{b,f}$ being fixed by comparison with (7.337) and (7.419).

A fluctuation determinant of this type occurs in the theory of superconductivity [32], with constant parameters ω , Δ . When applied to functions oscillating like $e^{-i\omega_m^f \tau}$, the matrix M becomes

$$M = \begin{pmatrix} -i\omega_m^f + \omega & \Delta \\ \Delta^* & \mp(-i\omega_m^f \pm \omega) \end{pmatrix}. \quad (7.559)$$

It is brought to diagonal form by what is called, in this context, a *Bogoliubov transformation* [33]

$$M \rightarrow M^d = \begin{pmatrix} -i\omega_m^f + \omega_\Delta & 0 \\ 0 & \mp(-i\omega_m^f \pm \omega_\Delta) \end{pmatrix}, \quad (7.560)$$

where ω_Δ is the frequency

$$\omega_\Delta = \sqrt{\omega^2 + \Delta^2}. \quad (7.561)$$

In a superconductor, these frequencies correspond to the energies of the quasi-particles associated with the electrons. They generalize the quasi-particles introduced in Landau's theory of Fermi liquids. The partition function (7.552) is then given by

$$\begin{aligned} Z_{\omega,\Delta} &= \mathcal{N}^{b,f} \det \begin{pmatrix} \partial_\tau + \omega & \Delta \\ \Delta^* & \mp \partial_\tau \pm \omega \end{pmatrix}^{\mp 1/2} \\ &= \mathcal{N}^{b,f} [\det(-\partial_\tau^2 + \omega_\Delta^2)]^{\mp 1/2} = \begin{cases} [2 \sinh(\hbar\beta\omega_\Delta/2)]^{-1}, \\ 2 \cosh(\hbar\beta\omega_\Delta/2), \end{cases} \end{aligned} \quad (7.562)$$

for bosons and fermions, respectively. This is equal to the partition function of a symmetrized Hamilton operator

$$\hat{H} = \frac{\omega_\Delta}{2} \Delta (\hat{a}^\dagger \hat{a} + \hat{a} \hat{a}^\dagger) = \omega_\Delta \left(\hat{a}^\dagger \hat{a} \pm \frac{1}{2} \right), \quad (7.563)$$

with the eigenvalue spectrum $\omega_\Delta (n \pm \frac{1}{2})$, where $n = 0, 1, 2, 3, \dots$ for bosons and $n = 0, 1$ for fermions:

$$Z_{\omega,\Delta} = \sum_n^{\infty,1} e^{-\hbar\omega_\Delta(n \pm 1/2)\beta}. \quad (7.564)$$

In the second-quantized interpretation where zero-point energies are omitted, this becomes

$$Z_{\omega,\Delta} = \begin{cases} (1 - e^{-\hbar\beta\omega_\Delta})^{-1}, \\ (1 + e^{-\hbar\beta\omega_\Delta}). \end{cases} \quad (7.565)$$

7.14 Spatial Degrees of Freedom

In the path integral treatment of the last sections, the particles have been restricted to a particular momentum state \mathbf{p} . In a three-dimensional volume, the fields $a^*(\tau)$, $\Delta(\tau)$ and their frequency ω depend on \mathbf{p} . With this trivial extension one obtains a free *quantum field theory*.

7.14.1 Grand-Canonical Ensemble of Particle Orbits from Free Fluctuating Field

The free particle action becomes a sum over momentum states

$$\mathcal{A}_e[a^*, a] = \hbar \int_0^{\hbar\beta} d\tau \sum_{\mathbf{p}} \left[a_{\mathbf{p}}^* \partial_{\tau} a_{\mathbf{p}} + \omega(\mathbf{p}) a_{\mathbf{p}}^* a_{\mathbf{p}} \right]. \quad (7.566)$$

The time-sliced partition function is given by the product

$$\begin{aligned} Z &= \prod_{\mathbf{p}} \left\{ \det [\epsilon(1 - \epsilon\omega)\bar{\nabla} + \epsilon\omega(\mathbf{p})] \right\}^{\mp 1} \\ &= \begin{cases} \exp \left[-\sum_{\mathbf{p}} \log \left(1 - e^{-\hbar\beta\bar{\omega}_e(\mathbf{p})} \right) \right] & \text{for bosons,} \\ \exp \left[\sum_{\mathbf{p}} \log \left(1 + e^{-\hbar\beta\bar{\omega}_e(\mathbf{p})} \right) \right] & \text{for fermions.} \end{cases} \end{aligned} \quad (7.567)$$

The free energy

$$F = -k_B T \log Z \quad (7.568)$$

is for bosons

$$F = k_B T \sum_{\mathbf{p}} \log \left(1 - e^{-\hbar\beta\bar{\omega}_e(\mathbf{p})} \right), \quad (7.569)$$

and for fermions

$$F = -k_B T \sum_{\mathbf{p}} \log \left(1 + e^{-\hbar\beta\bar{\omega}_e(\mathbf{p})} \right). \quad (7.570)$$

In a large volume, the momentum sum may be replaced by the integral

$$\sum_{\mathbf{p}} \rightarrow \int \frac{d^D p V}{(2\pi\hbar)^D}. \quad (7.571)$$

For infinitely thin time slices, $\epsilon \rightarrow 0$ and $\bar{\omega}_e(\mathbf{p})$ reduces to $\omega(\mathbf{p})$ and the expressions (7.569), (7.570) turn into the usual free energies of bosons and fermions. They agree completely with the expressions (7.46) and (7.220) derived from the sum over orbits.

Next we may introduce a fluctuating field in space and imaginary time

$$\psi(\mathbf{x}, \tau) = \frac{1}{\sqrt{V}} \sum_{\mathbf{p}} e^{i\mathbf{p}\mathbf{x}} a_{\mathbf{p}}(\tau), \quad (7.572)$$

and rewrite the action (7.566) in the local form

$$\mathcal{A}_e[\psi^*, \psi] = \int_0^{\hbar\beta} d\tau \int d^D x \left[\psi^*(\mathbf{x}, \tau) \hbar \partial_{\tau} \psi(\mathbf{x}, \tau) + \frac{\hbar^2}{2M} \nabla \psi^*(\mathbf{x}, \tau) \nabla \psi(\mathbf{x}, \tau) \right]. \quad (7.573)$$

The partition function is given by the functional integral

$$Z = \oint \mathcal{D}\psi \mathcal{D}\psi^* e^{-\mathcal{A}_e[\psi^*, \psi]/\hbar}. \quad (7.574)$$

Thus we see that the functional integral over a fluctuating field yields precisely the same partition function as the sum over a grand-canonical ensemble of fluctuating orbits. Bose or Fermi statistics are naturally accounted for by using complex or Grassmann field variables with periodic or antiperiodic boundary conditions, respectively. The theory based on the action (7.573) is completely equivalent to the second-quantized theory of field operators.

In order to distinguish the second-quantized or quantum field description of many particle systems from the former path integral description of many particle orbits, the former is referred to as the *first-quantized* approach, or also the *world-line* approach.

The action (7.573) can be generalized further to include an external potential $V(\mathbf{x}, \tau)$, i.e., it may contain a general Schrödinger operator $\hat{H}(\tau) = \hat{\mathbf{p}}^2 + V(\mathbf{x}, \tau)$ instead of the gradient term:

$$\mathcal{A}_e[\psi^*, \psi] = \int_0^{\hbar\beta} d\tau \int d^D x \left\{ \psi^*(\mathbf{x}, \tau) \hbar \partial_\tau \psi(\mathbf{x}, \tau) + \psi^*(\mathbf{x}, \tau) [\hat{H}(\tau) - \mu] \psi(\mathbf{x}, \tau) \right\}. \quad (7.575)$$

For the sake of generality we have also added a chemical potential to enable the study of grand-canonical ensembles. This action can be used for a second-quantized description of the free Bose gas in an external magnetic trap potential $V(\mathbf{x})$, which would, of course, lead to the same results as the first-quantized approach in Section 7.2.4. The free energy associated with this action

$$F = \frac{1}{\beta} \text{Tr} \log[\hbar \partial_\tau + \hat{H}(\tau) - \mu] \quad (7.576)$$

was calculated in Eq. (3.139) as an expansion

$$F = \frac{1}{2\hbar\beta} \text{Tr} \left[\int_0^{\hbar\beta} d\tau \hat{H}(\tau) \right] - \frac{1}{\beta} \sum_{n=1}^{\infty} \frac{1}{n} \text{Tr} \left\{ \hat{T} e^{-n \int_0^{\hbar\beta} d\tau'' [\hat{H}(\tau'') - \mu]/\hbar} \right\}, \quad (7.577)$$

The sum can be evaluated in the semiclassical expansion developed in Section 4.9. For simplicity, we consider here only time-independent external potentials, where we must calculate $\text{Tr} [e^{-n\beta(\hat{H}-\mu)}]$. Its semiclassical limit was given in Eq. (4.258) continued to imaginary time. From this we obtain

$$F = \frac{1}{2} \text{Tr} \hat{H} - \frac{1}{\beta} \frac{1}{\sqrt{2\pi\hbar^2\beta/M}^D} \sum_{n=1}^{\infty} \int d^D x \frac{[z(\mathbf{x})]^n}{n^{D/2+1}}, \quad (7.578)$$

where $z(\mathbf{x}) \equiv e^{-\beta[V(\mathbf{x})-\mu]}$ is the local fugacity (7.24). The sum agrees with the previous first-quantized result in (7.132) and (7.133). The first term is due to the symmetric treatment of the fields in the action (7.575) [recall the discussion after Eq. (7.340)].

One may calculate quantum corrections to this expansion by including the higher gradient terms of the semiclassical expansion (4.258). If the potential is time-dependent, the expansion (4.258) must be generalized accordingly.

7.14.2 First versus Second Quantization

There exists a simple set of formulas which illustrates nicely the difference between first and second quantization, i.e., between path and field quantization. Both may be thought of as being based on two different representations of the Dirac δ -function. The first-quantized representation is

$$\delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a) = \int_{\mathbf{x}(t_a)=\mathbf{x}_a}^{\mathbf{x}(t_b)=\mathbf{x}_b} \mathcal{D}^D x \oint \frac{\mathcal{D}^D p}{(2\pi\hbar)^D} e^{(i/\hbar) \int_{t_a}^{t_b} dt \mathbf{p}\dot{\mathbf{x}}}, \quad (7.579)$$

the second-quantized representation

$$i\hbar\delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a)\delta(t_b - t_a) = \oint \mathcal{D}\psi \mathcal{D}\psi^* \psi(\mathbf{x}_b, t_b)\psi^*(\mathbf{x}_a, t_a) e^{(i/\hbar) \int d^D x \int_{-\infty}^{\infty} dt \psi^*(\mathbf{x}, t)\psi(\mathbf{x}, t)}. \quad (7.580)$$

The first representation is turned into a transition amplitude by acting upon it with the time-evolution operator $e^{-i\hat{H}(t_b-t_a)}$, which yields

$$\langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = e^{i\hat{H}(t_b-t_a)} \delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a) = \int \mathcal{D}^D x \oint \frac{\mathcal{D}^D p}{(2\pi\hbar)^D} e^{(i/\hbar) \int_{t_a}^{t_b} dt (\mathbf{p}\dot{\mathbf{x}} - H)}. \quad (7.581)$$

By multiplying this with the Heaviside function $\Theta(t_b - t_a)$, we obtain the solution of the inhomogeneous Schrödinger equation

$$(i\hbar\partial_t - \hat{H})\Theta(t_b - t_a)\langle \mathbf{x}_b t_b | \mathbf{x}_a t_a \rangle = i\hbar\delta^{(D)}(\mathbf{x}_b - \mathbf{x}_a)\delta(t_b - t_a). \quad (7.582)$$

This may be expressed as a path integral representation for the resolvent

$$\left\langle \mathbf{x}_b t_b \left| \frac{i\hbar}{i\hbar\partial_t - \hat{H}} \right| \mathbf{x}_a t_a \right\rangle = \Theta(t_b - t_a) \int_{\mathbf{x}(t_a)=\mathbf{x}_a}^{\mathbf{x}(t_b)=\mathbf{x}_b} \mathcal{D}^D x \oint \frac{\mathcal{D}^D p}{(2\pi\hbar)^D} e^{(i/\hbar) \int_{t_a}^{t_b} dt (\mathbf{p}\dot{\mathbf{x}} - H)}. \quad (7.583)$$

The same quantity is obtained from the second representation (7.580) by changing the integrand in the exponent from $\psi^*(\mathbf{x}, t)\psi(\mathbf{x}, t)$ to $\psi^*(\mathbf{x}, t)(i\hbar\partial_t - \hat{H})\psi(\mathbf{x}, t)$:

$$\begin{aligned} & \left\langle \mathbf{x}_b t_b \left| \frac{i\hbar}{i\hbar\partial_t - \hat{H}} \right| \mathbf{x}_a t_a \right\rangle \\ &= \oint \mathcal{D}\psi \mathcal{D}\psi^* \psi(\mathbf{x}_b, t_b)\psi^*(\mathbf{x}_a, t_a) e^{(i/\hbar) \int d^D x \int_{-\infty}^{\infty} dt \psi^*(\mathbf{x}, t)(i\hbar\partial_t - \hat{H})\psi(\mathbf{x}, t)}. \end{aligned} \quad (7.584)$$

This is the second-quantized functional integral representation of the resolvent.

7.14.3 Interacting Fields

The interaction between particle orbits in a grand-canonical ensemble can be accounted for by anharmonic terms in the particle fields. A pair interaction between orbits, for example, corresponds to a fourth-order self interaction. An example is the interaction in the Bose-Einstein condensate corresponding to the energy in Eq. (7.101). Expressed in terms of the fields it reads

$$\mathcal{A}_e^{\text{int}}[\psi^*, \psi] = - \int_0^{\hbar\beta} d\tau \Delta E = - \frac{g}{2} \int_0^{\hbar\beta} d\tau \int d^3x \psi^*(\mathbf{x}, \tau + \eta) \psi^*(\mathbf{x}, \tau + \eta) \psi(\mathbf{x}, \tau) \psi(\mathbf{x}, \tau), \quad (7.585)$$

where $\eta > 0$ is an infinitesimal time shift. It is then possible to develop a perturbation theory in terms of Feynman diagrams by complete analogy with the treatment in Section 3.20 of the anharmonic oscillator with a fourth-order self interaction. The free correlation function is the momentum sum of oscillator correlation functions:

$$\langle \psi(\mathbf{x}, \tau) \psi^*(\mathbf{x}', \tau') \rangle = \sum_{\mathbf{p}, \mathbf{p}'} \langle a_{\mathbf{p}}(\tau) a_{\mathbf{p}'}^*(\tau') \rangle e^{i(\mathbf{p}\mathbf{x} - \mathbf{p}'\mathbf{x}')} = \sum_{\mathbf{p}} \langle a_{\mathbf{p}}(\tau) a_{\mathbf{p}}^*(\tau') \rangle e^{i\mathbf{p}(\mathbf{x} - \mathbf{x}')}. \quad (7.586)$$

The small $\eta > 0$ in (7.585) is necessary to specify the side of the jump of the correlation functions (recall Fig. 3.2). The expectation value of ΔE is given by (7.101), with a prefactor g rather than $g/2$ due to the two possible Wick contractions. Inserting the periodic correlation function (7.541), we obtain the Fourier integral

$$\langle \psi(\mathbf{x}, \tau) \psi^*(\mathbf{x}', \tau') \rangle = \sum_{\mathbf{p}} (1 + n_{\omega_{\mathbf{p}}}) e^{-\omega_{\mathbf{p}}(\tau - \tau') + i\mathbf{p}(\mathbf{x} - \mathbf{x}')}. \quad (7.587)$$

Recalling the representation (3.287) of the periodic Green function in terms of a sum over Matsubara frequencies, this can also be written as

$$\langle \psi(\mathbf{x}, \tau) \psi^*(\mathbf{x}', \tau') \rangle = \frac{1}{\hbar\beta} \sum_{\omega_m, \mathbf{p}} \frac{-1}{i\omega_m - \omega_{\mathbf{p}}} e^{-i\omega_m(\tau - \tau') + i\mathbf{p}(\mathbf{x} - \mathbf{x}')}. \quad (7.588)$$

The terms in the free energies (7.102) and (7.107) with the two parts (7.108) and (7.109) can then be shown to arise from the Feynman diagrams in the first line of Fig. 3.7.

In a grand-canonical ensemble, the energy $\hbar\omega_{\mathbf{p}}$ in (7.588) is replaced by $\hbar\omega_{\mathbf{p}} - \mu$. The same replacement appears in $\omega_{\mathbf{p}}$ of Eq. (7.587) which brings the distribution function $n_{\omega_{\mathbf{p}}}$ to [recall (7.542)]

$$n_{\omega_{\mathbf{p}} - \mu/\hbar} = \frac{1}{z^{-1} e^{\beta\hbar\omega_{\mathbf{p}}} - 1}, \quad (7.589)$$

where z is the fugacity $z = e^{\beta\mu}$. The expansion of the Feynman integrals in powers of z yields directly the expressions (7.102) and (7.107).

7.14.4 Effective Classical Field Theory

For the purpose of studying phase transitions, a functional integral over fields $\psi(\mathbf{x}, \tau)$ with an interaction (7.585) must usually be performed at a finite temperature. Then is often advisable to introduce a direct three-dimensional extension of the effective classical potential $V^{\text{eff cl}}(x_0)$ introduced in Section 3.25 and used efficiently in Chapter 5. In a field theory we can set up, by analogy, an *effective classical action* which is a functional of the three-dimensional field with zero Matsubara frequency $\phi(\mathbf{x}) \equiv \psi_0(\mathbf{x})$. The advantages come from the reasons discussed in Section 3.25, that

the zero-frequency fluctuations have a linearly diverging fluctuation width at high temperature, following the Dulong-Petit law. Thus only the nonzero-modes can be treated efficiently by the perturbative methods explained in Subsection 3.25.6.

By analogy with the splitting of the measure of path integration in Eq. (3.808), we may factorize the functional integral (7.574) into zero- and nonzero-Matsubara frequency parts as follows:

$$Z = \oint \mathcal{D}\psi \mathcal{D}\psi^* e^{-\mathcal{A}_e[\psi^*, \psi]} = \oint \mathcal{D}\psi_0 \mathcal{D}\psi_0^* \oint \mathcal{D}'\psi \mathcal{D}'\psi^* e^{-\mathcal{A}_e[\psi^*, \psi]}, \quad (7.590)$$

and introduce the Boltzmann factor [compare (3.813)] contain the effective classical action

$$B[\psi_0^*, \psi_0] \equiv e^{-\mathcal{A}^{\text{eff cl}}[\psi_0^*, \psi_0]} \equiv \oint \mathcal{D}'\psi \mathcal{D}'\psi^* e^{-\mathcal{A}_e[\psi^*, \psi]}, \quad (7.591)$$

to express the partition function as a *functional integral* over time-independent fields in three dimensions as:

$$Z = \oint \mathcal{D}\psi_0 \mathcal{D}\psi_0^* e^{-\mathcal{A}^{\text{eff cl}}[\psi_0^*, \psi_0]}. \quad (7.592)$$

In Subsection 3.25.1 we have seen that the full effective classical potential $V^{\text{eff cl}}(x_0)$ in Eq. (3.812) reduces in the high-temperature limit to the initial potential $V(x_0)$. For the same reason, the full effective classical action in the functional integral (7.590) can be approximated at high temperature by the *bare effective classical action*, which is simply the zero-frequency part of the initial action:

$$\mathcal{A}_b^{\text{eff cl}}[\psi_0^*, \psi_0] = \beta \int d^3x \left\{ \psi_0^*(\mathbf{x}) \left(-\frac{1}{2m} \nabla^2 - \mu \right) \psi_0(\mathbf{x}) + \frac{2\pi a}{m} [\psi_0^*(\mathbf{x}) \psi_0(\mathbf{x})]^2 \right\}. \quad (7.593)$$

This follows directly from the fact that, at high temperature, the fluctuations in the functional integral (7.591) are strongly suppressed by the large Matsubara frequencies in the kinetic terms.

Remarkably, the absence of a shift in the critical temperature in the first-order energy (7.113) deduced from Eq. (7.116) implies that the chemical potential in the effective classical action does not change at this order [34]. For this reason, the lowest-order shift in the critical temperature of a weakly interacting Bose-Einstein condensate can be calculated entirely from the three-dimensional effective classical field theory (7.590) with the bare effective classical action (7.593) in the Boltzmann factor.

The action (7.593) may be brought to a more conventional form by introducing the differently normalized two-component fields $\phi = (\phi_1, \phi_2)$ related to the original complex field ψ by $\psi(\mathbf{x}) = \sqrt{MT}[\phi_1(\mathbf{x}) + i\phi_2(\mathbf{x})]$. If we also define a square mass $m^2 \equiv -2M\mu$ and a quartic coupling $u = 48\pi aMT$, the bare effective classical action reads

$$\mathcal{A}_b^{\text{eff cl}}[\psi_0^*, \psi_0] = \mathcal{A}[\phi] = \int d^3x \left[\frac{1}{2} |\nabla\phi|^2 + \frac{1}{2} m^2 \phi^2 + \frac{u}{4!} (\phi^2)^2 \right]. \quad (7.594)$$

In the field theory governed by the action (7.594), the relation (7.111) for the shift of the critical temperature to lowest order in the coupling constant becomes

$$\begin{aligned} \frac{\Delta T_c}{T_c^{(0)}} &\approx -\frac{2}{3} \frac{mT_c^{(0)}}{n} \langle \Delta \phi^2 \rangle = -\frac{4\pi}{3} \frac{(mT_c^{(0)})^2}{n} 4! \left\langle \frac{\Delta \phi^2}{u} \right\rangle a \\ &= -\frac{4\pi}{3} \frac{(2\pi)^2}{[\zeta(3/2)]^{4/3}} 4! \left\langle \frac{\Delta \phi^2}{u} \right\rangle a n^{1/3}, \end{aligned} \quad (7.595)$$

where $\langle \Delta \phi^2 \rangle$ is the shift in the expectation value of ϕ^2 caused by the interaction. Since a repulsive interaction pushes particles apart, $\langle \Delta \phi^2 \rangle$ is negative, thus explaining the positive shift in the critical temperature. The evaluation of the expectation value $\langle \Delta \phi^2 \rangle$ from the path integral (7.590) with the bare three-dimensional effective classical action (7.594) in the exponent can now proceed within one of the best-studied field theories in the literature [51]. The theoretical tools for calculating strong-coupling results in this theory are well developed, and this has made it possible to drive the calculations of the shift to the five-loop order [21].

Some low-order corrections to the effective classical action (7.593) have been calculated from the path integral (7.591) in Ref. [34].

7.15 Bosonization

The path integral formulation of quantum-mechanical systems is very flexible. Just as integrals can be performed in different variables of integration, so can path integrals in different path variables. This has important applications in many-body systems, which show a rich variety of so-called collective phenomena. Practically all fermion systems show collective excitations such as sound, second sound, and spin waves. These are described phenomenologically by bosonic fields. In addition, there are phase transitions whose description requires a bosonic order parameter. Superconductivity of electron systems is a famous example where a bosonic order parameter appears in a fermion system—the energy gap. In all these cases it is useful to transform the initial path variables to so-called collective path variables, in higher dimensions these become *collective fields* [32].

Let us illustrate the technique with simple a model defined by the Lagrangian

$$L(t) = a^*(t) i \partial_t a(t) - \frac{\varepsilon}{2} [a^*(t) a(t)]^2, \quad (7.596)$$

where a^* , a are commuting or anticommuting variables. All Green functions can be calculated from the generating functional

$$Z[\eta^*, \eta] = N \int \mathcal{D}a^* \mathcal{D}a \exp \left[i \int dt (L + \eta^* a + a^* \eta) \right], \quad (7.597)$$

where we have omitted an irrelevant overall factor.

In operator language, the model is defined by the Hamiltonian operator

$$\hat{H} = \varepsilon (\hat{a}^\dagger \hat{a})^2 / 2, \quad (7.598)$$

where \hat{a}^\dagger , \hat{a} are creation and annihilation operator of either a boson or a fermion at a point. In the boson case, the eigenstates are

$$|n\rangle = \frac{1}{\sqrt{n!}}(\hat{a}^\dagger)^n|0\rangle, \quad n = 0, 1, 2, \dots, \quad (7.599)$$

with an energy spectrum

$$E_n = \varepsilon \frac{n^2}{2}. \quad (7.600)$$

In the fermion case, there are only two solutions

$$|0\rangle \quad \text{with} \quad E_0 = 0, \quad (7.601)$$

$$|1\rangle = a^\dagger|0\rangle \quad \text{with} \quad E_1 = \frac{\varepsilon}{2}. \quad (7.602)$$

Here the Green functions are obtained from the generating functional

$$Z[\eta^\dagger, \eta] = \langle 0 | \hat{T} \exp \left[i \int dt (\eta^* \hat{a} + \hat{a}^\dagger \eta) \right] | 0 \rangle, \quad (7.603)$$

where \hat{T} is the time ordering operator (1.241). The functional derivatives with respect to the sources η^* , η generate all Green functions of the type (3.299) at $T = 0$.

7.15.1 Collective Field

At this point we introduce an additional *collective field* via the Hubbard-Stratonovich transformation [52]

$$\exp \left\{ -i \frac{\varepsilon}{2} \int dt [a^*(t)a(t)]^2 \right\} = N \int \mathcal{D}\rho(t) \exp \left\{ i \int dt \left[\frac{\rho^2(t)}{2\varepsilon} - \rho(t)a^*(t)a(t) \right] \right\}, \quad (7.604)$$

where N is some irrelevant factor. Equivalently we multiply the partition function (7.597) with the trivial Gaussian path integral

$$1 = N \int \mathcal{D}\rho(t) \exp \left\{ \int dt \frac{1}{2\varepsilon} [\rho(t) - \varepsilon a^\dagger(t)a(t)]^2 \right\}, \quad (7.605)$$

to obtain the generating functional

$$\begin{aligned} Z[\eta^\dagger, \eta] &= N \int \mathcal{D}a^* \mathcal{D}a \mathcal{D}\rho \\ &\times \exp \left\{ \int dt \left[a^*(t) i \partial_t a(t) - \varepsilon \rho(t) a^*(t) a(t) + \frac{\rho^2(t)}{2\varepsilon} + \eta^*(t) a(t) + a^*(t) \eta(t) \right] \right\}. \end{aligned} \quad (7.606)$$

From (7.604) we see that the collective field $\rho(t)$ fluctuates harmonically around ε times particle density. By extremizing the action in (7.606) with respect to $\rho(t)$ we obtain the classical equality:

$$\rho(t) = \varepsilon a^*(t)a(t). \quad (7.607)$$

The virtue of the Hubbard-Stratonovich transformation is that the fundamental variables a^* , a appear now quadratically in the action and can be integrated out to yield a path integral involving only the collective variable $\rho(t)$:

$$Z[\eta^*, \eta] = N \int \mathcal{D}\rho \exp \left\{ i\mathcal{A}[\rho] - \int dt dt' \eta^*(t) G_\rho(t, t') \eta(t') \right\}, \quad (7.608)$$

with the collective action

$$\mathcal{A}[\rho] = \pm i \text{Tr} \log (iG_\rho^{-1}) + \int dt \frac{\rho^2(t)}{2}, \quad (7.609)$$

where G_ρ denotes the Green function of the fundamental path variables in an external $\rho(t)$ background potential, which satisfies [compare (3.75)]

$$[i\partial_t - \rho(t)] G_\rho(t, t') = i\delta(t - t'). \quad (7.610)$$

The Green function was found in Eq. (3.124). Here we find the solution once more in a different way which will be useful in the sequel. We introduce an auxiliary field

$$\varphi(t) = \int^t \rho(t') dt', \quad (7.611)$$

in terms of which $G_\rho(t, t')$ is simply

$$G_\rho(t, t') = e^{-i\varphi(t)} e^{i\varphi(t')} G_0(t - t'), \quad (7.612)$$

with G_0 being the free-field propagator of the fundamental particles. At this point one has to specify the boundary condition on $G_0(t - t')$. They have to be adapted to the physical situation of the system. Suppose the time interval is infinite. Then G_0 is given by Eq. (3.100), so that we obtain, as in (3.124),

$$G_\rho(t, t') = e^{-i\varphi(t)} e^{i\varphi(t')} \bar{\Theta}(t - t'). \quad (7.613)$$

The Heaviside function $\bar{\Theta}$ defined in Eq. (1.313) corresponds to $\rho(t)$ coupling to the symmetric operator combination $(\hat{a}^\dagger \hat{a} + \hat{a} \hat{a}^\dagger)/2$. The products $\hat{a}^\dagger \hat{a}$ in the Hamiltonian (7.598), however, have the creation operators left of the annihilation operators. In this case we must use the Heaviside function $\Theta(t - t')$ of Eq. (1.304). If this function is inserted into (7.613), the right-hand side of (7.613) vanishes at $t = t'$.

Using this property we see that the functional derivative of the tracelog in (7.609) vanishes:

$$\frac{\delta}{\delta \rho(t)} \left\{ \pm i \text{Tr} \log (iG_\rho^{-1}) \right\} = \frac{\delta}{\delta \rho(t)} \left\{ \pm i \text{Tr} \log [i\partial_t - \rho(t)] \right\} = \mp G_\rho(t, t')|_{t'=t} = 0. \quad (7.614)$$

This makes the tracelog an irrelevant constant. The generating functional is then simply

$$Z[\eta^\dagger, \eta] = N \int \mathcal{D}\varphi(t) \exp \left\{ \frac{i}{2\varepsilon} \int dt \dot{\varphi}(t)^2 - \int dt dt' \eta^\dagger(t) \eta(t') e^{-i\varphi(t)} e^{-i\varphi(t')} \Theta(t - t') \right\}, \quad (7.615)$$

where we have used the Jacobian

$$\mathcal{D}\rho = \mathcal{D}\varphi \text{Det}(\partial_t) = \mathcal{D}\varphi, \quad (7.616)$$

since $\text{Det}(\partial_t) = 1$ according to (2.537). Observe that the transformation (7.611) provides $\varphi(t)$ with a standard kinetic term $\dot{\varphi}^2(t)$.

The original theory has been transformed into a new theory involving the collective field φ . In a three-dimensional generalization of this theory to electron gases, the field φ describes density waves [32].

7.15.2 Bosonized versus Original Theory

The first term in the bosonized action in (7.615) is due to a Lagrangian

$$L_0(t) = \frac{1}{2\varepsilon} \dot{\varphi}(t)^2 \quad (7.617)$$

describing free particles on the infinite φ -axis. Its correlation function is divergent and needs a small frequency, say κ , to exist. Its small- κ expansion reads

$$\begin{aligned} \langle \varphi(t)\varphi(t') \rangle &= \varepsilon \int \frac{d\omega}{2\pi} \frac{i}{\omega^2 - \kappa^2 + i\epsilon} e^{-i\omega(t-t')} \\ &= \frac{\varepsilon}{2\kappa} e^{-\kappa|t-t'|} = \frac{\varepsilon}{2\kappa} - \varepsilon \frac{i}{2} |t-t'| + \mathcal{O}(\kappa). \end{aligned} \quad (7.618)$$

The first term plays an important role in calculating the bosonized correlation functions generated by $Z[\eta^*, \eta]$ in Eq. (7.615). Differentiating this n times with respect to η and η^* and setting them equal to zero we obtain

$$\begin{aligned} G^{(n)}(t_n, \dots, t_1; t'_n, \dots, t'_1) &= (-1)^n \langle e^{-i\varphi(t_n)} \dots e^{-i\varphi(t_1)} e^{i\varphi(t'_n)} \dots e^{i\varphi(t'_1)} \rangle \\ &\times \sum_p \epsilon_p \Theta(t_{p_1} - t_1) \dots \Theta(t_{p_n} - t_1), \end{aligned} \quad (7.619)$$

where the sum runs over all permutations p of the time labels of $t_1 \dots t_n$ making sure that these times are all later than the times $t'_1 \dots t'_n$. The factor ϵ_p reflects the commutation properties of the sources η, η^* , being equal to 1 for all permutations if η and η^* commute. For Grassmann variables η, η^* , the factor ϵ_p is equal to -1 if the permutation p is odd. The expectation value is defined by the path integral

$$\langle \dots \rangle \equiv \frac{1}{Z[0, 0]} \int \mathcal{D}\varphi(t) \dots e^{(i/2\varepsilon) \int dt \dot{\varphi}(t)^2}. \quad (7.620)$$

Let us calculate the expectation value of the exponentials in (7.619), writing it as

$$\left\langle \exp \left[i \sum_{i=1}^{2n} q_i \varphi(t_i) \right] \right\rangle = \left\langle \exp \left[\sum_i \int dt \delta(t - t_i) q_i \varphi(t) \right] \right\rangle, \quad (7.621)$$

where we have numbered the times as t_1, t_2, \dots, t_{2n} rather than $t_1, t'_1, t_2, t'_2, \dots, t_n, t'_n$. Half of the $2n$ “charges” q_i are 1, the other half are -1 . Using Wick’s theorem in the form (3.310) we find

$$\begin{aligned} \left\langle e^{i \sum_{i=1}^{2n} q_i \varphi(t_i)} \right\rangle &= \exp \left[-\frac{1}{2} \int dt dt' \sum_{i=1}^{2n} q_i \delta(t - t_i) \langle \varphi(t) \varphi(t') \rangle (t') \sum_j q_j \delta(t - t_j) \right] \\ &= \exp \left[-\frac{1}{2} \sum_{i,j=1}^{2n} q_i q_j \langle \varphi(t_i) \varphi(t_j) \rangle \right]. \end{aligned} \quad (7.622)$$

Inserting here the small- κ expansion (7.618), we see that the $1/\kappa$ -term gives a pre-factor

$$\exp \left[-\frac{\varepsilon}{4\kappa} \left(\sum_i q_i \right)^2 \right], \quad (7.623)$$

which vanishes since the sum of all “charges” q_i is zero. Hence we can go to the limit $\kappa \rightarrow 0$ and obtain

$$\left\langle \exp \left[i \sum_{i=1}^{2n} q_i \varphi(t_i) \right] \right\rangle = \exp \left[\varepsilon \frac{i}{2} \sum_{i>j} q_i q_j |t_i - t_j| \right]. \quad (7.624)$$

Note that the limit $\kappa \rightarrow 0$ makes all correlation functions vanish which do not contain an equal number of $a^*(t)$ and $a(t)$ variables. It ensures “charge conservation”.

For one positive and one negative charge we obtain, after a multiplication by a Heaviside function $\Theta(t_1 - t'_1)$, the two-point function

$$G^{(2)}(t, t') = e^{-i\varepsilon(t-t')/2} \Theta(t - t'). \quad (7.625)$$

This agrees with the operator result derived from the generating functional (7.603), where

$$G^{(2)}(t, t') = \langle 0 | \hat{T} \hat{a}(t) \hat{a}^\dagger(t') | 0 \rangle = \Theta(t - t') \langle 0 | \hat{a}(t) \hat{a}^\dagger(t') | 0 \rangle e^{-i\varepsilon(t-t')/2} \Theta(t - t'). \quad (7.626)$$

Inserting the Heisenberg equation [recall (1.277)]

$$a(t) = e^{it\hat{H}} a e^{-it\hat{H}}, \quad a^\dagger(t') = e^{it'\hat{H}} a^\dagger e^{-it'\hat{H}}. \quad (7.627)$$

we find

$$\begin{aligned} \langle 0 | \hat{T} \hat{a}(t) \hat{a}^\dagger(t') | 0 \rangle &= \Theta(t - t') \langle 0 | e^{i\varepsilon(\hat{a}^\dagger \hat{a})^2 t/2} a e^{-\frac{i}{2}(\hat{a}^\dagger \hat{a})^2 (t-t')} \hat{a}^\dagger e^{-i(\hat{a}^\dagger \hat{a})^2 t'/2} | 0 \rangle \\ &= \Theta(t - t') \langle 1 | e^{-\frac{i}{2}(\hat{a}^\dagger \hat{a})^2 (t-t')} | 1 \rangle = \Theta(t - t') e^{-i\varepsilon(t-t')/2}. \end{aligned} \quad (7.628)$$

Let us compare the above calculations with an operator evaluation of the bosonized theory. The Hamiltonian operator associated with the Lagrangian (7.617) is $\hat{H} = \varepsilon \hat{p}^2/2$. The states in the Hilbert space are eigenstates of the momentum operator $\hat{p} = -i\partial/\partial\varphi$:

$$\{\varphi | p \} = \frac{1}{\sqrt{2\pi}} e^{ip\varphi}. \quad (7.629)$$

Here, curly brackets are a modified Dirac notation for states of the bosonized theory, which distinguishes them from the states of the original theory created by products of operators $\hat{a}^\dagger(t)$ acting on $|0\rangle$. In operator language, the generating functional of the theory (7.615) reads

$$Z[\eta^\dagger, \eta] = \frac{1}{\{0|0\rangle} \{0|\hat{T} \exp \left[- \int dt dt' \eta^\dagger(t) \eta(t') e^{-i\hat{\varphi}(t)} e^{i\hat{\varphi}(t')} \Theta(t-t') \right] |0\rangle, \quad (7.630)$$

where $\hat{\varphi}(t)$ are free-particle operators.

We obtain all Green functions of the initial operators $\hat{a}(t)$, $\hat{a}^\dagger(t)$ by forming functional derivatives of the generating functional $Z[\eta^\dagger, \eta]$ with respect to η^\dagger, η . Take, for instance, the two-point function

$$\langle 0|\hat{T}\hat{a}(t)\hat{a}^\dagger(t')|0\rangle = - \frac{\delta^{(2)} Z}{\delta \eta^\dagger(t) \delta \eta(t')} \Big|_{\eta^\dagger, \eta=0} = \frac{1}{\{0|0\rangle} \{0|e^{-i\hat{\varphi}(t)} e^{i\hat{\varphi}(t')} |0\rangle \Theta(t-t'). \quad (7.631)$$

Inserting here the Heisenberg equation (1.277),

$$\hat{\varphi}(t) = e^{i\varepsilon \frac{\hat{p}^2}{2} t} \hat{\varphi}(0) e^{-i\varepsilon \frac{\hat{p}^2}{2} t}, \quad (7.632)$$

we can evaluate the matrix element in (7.631) as follows:

$$\{0|e^{i\varepsilon \frac{\hat{p}^2}{2} t} 2e^{-i\hat{\varphi}(0)} e^{-i\varepsilon \frac{\hat{p}^2}{2} (t-t')} e^{i\hat{\varphi}(0)} e^{-i\varepsilon \frac{\hat{p}^2}{2} t'} |0\rangle = \{0|e^{-i\hat{\varphi}(0)} e^{-i\varepsilon \frac{\hat{p}^2}{2} (t-t')} e^{i\hat{\varphi}(0)} |0\rangle. \quad (7.633)$$

The state $e^{i\hat{\varphi}(0)} |0\rangle$ is an eigenstate of \hat{p} with unit momentum $|1\rangle$ and the same norm as $|0\rangle$, so that (7.633) equals

$$\frac{1}{\{0|0\rangle} \{1|1\rangle e^{-i\varepsilon(t-t')/2} = e^{-i\varepsilon(t-t')/2} \quad (7.634)$$

and the Green function (7.631) becomes, as in (7.626) and (7.628):

$$\langle 0|\hat{T}\hat{a}(t)\hat{a}^\dagger(t')|0\rangle = e^{-i\varepsilon(t-t')/2} \Theta(t-t'). \quad (7.635)$$

Observe that the Fermi and Bose statistics of the original operators \hat{a}, \hat{a}^\dagger enters to result only via the commutation properties of the sources.

There exists also the opposite phenomenon that a bosonic theory possesses solutions which behave like fermions. This will be discussed in Section 8.12.

Appendix 7A Treatment of Singularities in Zeta-Function

Here we show how to evaluate the sums which determine the would-be critical temperatures of a Bose gas in a box and in a harmonic trap.

7A.1 Finite Box

According to Eqs. (7.83), (7.88), and (7.90), the relation between temperature $T = \hbar^2 \pi^2 / bML^2 k_B$ and the fugacity z_D at a fixed particle number N in a finite D -dimensional box is determined by the equation

$$N = N_n(T) + N_{\text{cond}}(T) = S_D(z_D) + \frac{z_D}{1 - z_D}, \quad (7A.1)$$

where $S_D(z_D)$ is the subtracted infinite sum

$$S_D(z_D) \equiv \sum_{w=1}^{\infty} [Z_1^D(wb) e^{wDb/2} - 1] z_D^w, \quad (7A.2)$$

containing the D th power of one-particle partition function in the box $Z_1(b) = \sum_{k=1}^{\infty} e^{-bk^2/2}$. The would-be critical temperature is found by equating this sum at $z_D = 1$ with the total particle number N . We shall rewrite $Z_1(b)$ as

$$Z_1(b) = e^{-b/2} \left[1 + e^{-3b/2} \sigma_1(b) \right], \quad (7A.3)$$

where $\sigma_1(b)$ is related to the elliptic theta function (7.85) by

$$\sigma_1(b) \equiv \sum_{k=2}^{\infty} e^{-(k^2-4)b/2} = \frac{e^{2b}}{2} \left[\vartheta_3(0, e^{-b/2}) - 1 - 2e^{-b/2} \right]. \quad (7A.4)$$

According to Eq. (7.87), this has the small- b behavior

$$\sigma_1(b) = \sqrt{\frac{\pi}{2b}} e^{2b} - e^{3b/2} - \frac{1}{2} e^{2b} + \dots \quad (7A.5)$$

The omitted terms are exponentially small as long as $b < 1$ [see the sum over m in Eq. (7.86)]. For large b , these terms become important to ensure an exponentially fast falloff like $e^{-3b/2}$. Inserting (7A.3) into (7A.2), we find

$$S_D(1) \equiv D \sum_{w=1}^{\infty} \left[\sigma_1(wb) e^{-3wb/2} + \frac{D-1}{2} \sigma_1^2(wb) e^{-6wb/2} + \frac{(D-1)(D-2)}{6} \sigma_1^3(wb) e^{-9wb/2} \right]. \quad (7A.6)$$

Inserting here the small- b expression (7A.5), we obtain

$$S_2(1) \equiv \sum_{w=1}^{\infty} \left(\frac{\pi}{2wb} e^{wb} - \sqrt{\frac{\pi}{2wb}} e^{wb} + \frac{1}{4} e^{wb} - 1 \right) + \dots, \quad (7A.7)$$

$$S_3(1) \equiv \sum_{w=1}^{\infty} \left(\sqrt{\frac{\pi}{2wb}}^3 e^{3wb/2} - \frac{3}{2} \frac{\pi}{2wb} e^{3wb/2} + \frac{3}{4} \sqrt{\frac{\pi}{2wb}} e^{3wb/2} - \frac{1}{8} e^{3wb/2} - 1 \right) + \dots, \quad (7A.8)$$

the dots indicating again exponentially small terms. The sums are convergent only for negative b , this being a consequence of the approximate nature of these expressions. If we evaluate them in this regime, the sums produce Polylogarithmic functions (7.34), and we find, using also $\sum_{w=1}^{\infty} 1 = \zeta(0) = -1/2$ from (2.522),

$$S_2(1) = \zeta_1(e^b) - \sqrt{\frac{\pi}{2b}} \zeta_{1/2}(e^b) + \frac{1}{4} \zeta_0(e^b) - \zeta(0) + \dots \quad (7A.9)$$

$$S_3(1) = \sqrt{\frac{\pi}{2b}}^3 \zeta_{3/2}(e^{3b/2}) - \frac{3}{2} \frac{\pi}{2b} \zeta_1(e^{3b/2}) + \frac{3}{4} \sqrt{\frac{\pi}{2b}} \zeta_1(e^{3b/2}) - \frac{1}{8} \zeta_0(e^{3b/2}) - \zeta(0) + \dots \quad (7A.10)$$

These expressions can now be expanded in powers of b with the help of the Robinson expansion (2.581). Afterwards, b is continued analytically to positive values and we obtain

$$S_2(1) = -\frac{\pi}{2b} \log(C_2 b) - \sqrt{\frac{\pi}{2b}} \zeta(1/2) + \frac{1}{8}(3 - 2\pi) + \mathcal{O}(b^{1/2}), \tag{7A.11}$$

$$S_3(1) = \sqrt{\frac{\pi}{2b}}^3 \zeta(3/2) + \frac{3\pi}{4b} \log(C_3 b) + \frac{3}{4} \sqrt{\frac{\pi}{2b}} \zeta(1/2)(1 + \pi) + \frac{9}{16}(1 + \pi) + \mathcal{O}(b^{1/2}). \tag{7A.12}$$

The constants $C_{2,3}, C'_{2,3}$ inside the logarithms turn out to be complex, implying that the limiting expressions (7A.7) and (7A.8) cannot be used reliably. A proper way to proceed goes as follows. We subtract from $S_D(1)$ terms which remove the small- b singularities by means of modifications of (7A.7) and (7A.8) which have the same small- b expansion up to b^0 :

$$\tilde{S}_2(1) \equiv \sum_{w=1}^{\infty} \left(\frac{\pi}{2wb} - \sqrt{\frac{\pi}{2wb}} + \frac{4\pi - 3}{4} \right) e^{-wb} + \dots, \tag{7A.13}$$

$$\tilde{S}_3(1) \equiv \sum_{w=1}^{\infty} \left[\sqrt{\frac{\pi}{2wb}}^3 - \frac{3}{2} \frac{\pi}{2wb} + \frac{3}{4} (1 + 2\pi) \sqrt{\frac{\pi}{2wb}} - \frac{9}{8} (1 + 2\pi) \right] e^{-3wb/2} + \dots \tag{7A.14}$$

In these expressions, the sums over w can be performed for positive b yielding

$$\tilde{S}_2(1) \equiv \frac{\pi}{2b} \zeta_1(e^{-b}) - \sqrt{\frac{\pi}{2b}} \zeta_{1/2}(e^{-b}) + \frac{4\pi - 3}{4} \zeta_0(e^{-b}) + \dots, \tag{7A.15}$$

$$\tilde{S}_3(1) \equiv \sqrt{\frac{\pi}{2b}}^3 \zeta_{3/2}(e^{-3b/2}) - \frac{3}{2} \frac{\pi}{2b} \zeta_1(e^{-3b/2}) + \frac{3}{4} (1 + 2\pi) \sqrt{\frac{\pi}{2b}} \zeta_{1/2}(e^{-3b/2}) - \frac{9}{8} (1 + 2\pi) \zeta_0(e^{-3b/2}) + \dots \tag{7A.16}$$

Inserting again the Robinson expansion (2.581), we obtain once more the above expansions (7A.11) and (7A.12), but now with the well-determined real constants

$$\tilde{C}_2 = e^{3/2\pi - 2 + \sqrt{2}} \approx 0.8973, \quad \tilde{C}_3 = \frac{3}{2} e^{-2 + 1/\sqrt{3} - 1/\pi} \approx 0.2630. \tag{7A.17}$$

The subtracted expressions $S_D(1) - \tilde{S}_D(1)$ are smooth near the origin, so that the leading small- b behavior of the sums over these can simply be obtained from a numeric integral over w :

$$\int_0^{\infty} dw [S_2(1) - \tilde{S}_2(1)] = -\frac{1.1050938}{b}, \quad \int_0^{\infty} dw [S_3(1) - \tilde{S}_3(1)] = 3.0441. \tag{7A.18}$$

These modify the constants $\tilde{C}_{2,3}$ to

$$C_2 = 1.8134, \quad C_3 = 0.9574. \tag{7A.19}$$

The corrections to the sums over $S_D(1) - \tilde{S}_D(1)$ are of order b^0 and higher and already included in the expansions (7A.11) and (7A.12), which were only unreliable as far as $C_{2,3}$ are concerned.

Let us calculate from (7A.12) the finite-size correction to the critical temperature by equating $S_3(1)$ with N . Expressing this in terms of $b_c^{(0)}$ via (7.92), and introducing the ratio $\hat{b}_c \equiv b_c/b_c^{(0)}$ which is close to unity, we obtain the expansion in powers of the small quantity $2b_c^{(0)}/\pi = [\zeta(3/2)/N]^{2/3}$:

$$\hat{b}_c^{3/2} = 1 + \sqrt{\frac{2b_c^{(0)}}{\pi}} \frac{3\sqrt{\hat{b}_c}}{2\zeta(3/2)} \log(C_3 b_c^{(0)} \hat{b}_c) + \frac{2b_c^{(0)}}{\pi} \frac{3}{4\zeta(3/2)} \zeta(1/2)(1 + \pi) \hat{b}_c + \dots \tag{7A.20}$$

To lowest order, the solution is simply

$$\hat{b}_c = 1 + \sqrt{\frac{2b_c^{(0)}}{\pi}} \frac{1}{\zeta(3/2)} \log(C_3 b_c^{(0)}) + \dots, \tag{7A.21}$$

yielding the would-be critical temperature to first in $1/N^{1/3}$ as stated in (7.94). To next order, we insert into the last term the zero-order solution $\hat{b}_c \approx 1$, and in the second term the first-order solution (7A.21) to find

$$\begin{aligned} \hat{b}_c^{3/2} &= 1 + \frac{3}{2} \sqrt{\frac{2b_c^{(0)}}{\pi}} \frac{1}{\zeta(3/2)} \log(C_3 b_c^{(0)}) \\ &+ \frac{2b_c^{(0)}}{\pi} \frac{3}{4\zeta(3/2)} \left\{ \zeta(1/2)(1 + \pi) + \frac{1}{\zeta(3/2)} \left[2\log(C_3 b_c^{(0)}) + \log^2(C_3 b_c^{(0)}) \right] \right\} + \dots \end{aligned} \tag{7A.22}$$

Replacing $b_c^{(0)}$ by $(2/\pi) [\zeta(3/2)/N]^{2/3}$, this gives us the ratio $(T_c^{(0)}/T_c)^{3/2}$ between finite- and infinite size critical temperatures T_c and $T_c^{(0)}$. The first and second-order corrections are plotted in Fig. 7.12, together with precise results from numeric solution of the equation $N = S_3(1)$.

Figure 7.12 Finite-size corrections to the critical temperature for $N = 300$ to infinity calculated once from the formula $N = S_3(1)$ (solid curve) and once from the expansion (7A.22) (short-dashed up to order $[b_c^{(0)}]^{1/2} \propto 1/N^{1/3}$, long-dashed up to the order $b_c^{(0)} \propto 1/N^{2/3}$). The fat dots show the peaks in the second derivative $d^2 N_{\text{cond}}(T)/dT^2$. The small dots show the corresponding values for canonical ensembles, for comparison.

7A.2 Harmonic Trap

The sum relevant for the would-be phase transition in a harmonic trap is (7.138),

$$S_D(b, z_D) = \sum_{w=1}^{\infty} \left[\frac{1}{(1 - e^{-wb})^D} - 1 \right] z_D^w, \tag{7A.23}$$

which determines the number of normal particles in the harmonic trap via Eq. (7.139). We consider only the point $z_D = 1$ which determines the critical temperature by the condition $N_n = N$. Restricting ourselves to the physical cases $D = 1, 2, 3$, we rewrite the sum as

$$S_D(b, 1) = \sum_{w=1}^{\infty} D \left[e^{-wb} - \frac{(D-1)}{2} e^{-2wb} + \frac{(D-1)(D-2)}{6} e^{-3wb} \right] \frac{1}{(1 - e^{-wb})^D}. \tag{7A.24}$$

According to the method developed in the evaluation of Eq. (2.581) we obtain such a sum in two steps. First we go to small b where the sum reduces to an integral over w . After this we calculate the difference between sum and integral by a naive power series expansion.

As it stands, the sum (7A.24) cannot be converted into an integral due to singularities at $w = 0$. These have to be first removed by subtractions. Thus we decompose $S_D(b, 1)$ into a subtracted sum plus a remainder as

$$S_D(b, 1) = \bar{S}_D(b, 1) + \Delta_D S_D(b, 1) + b \frac{D}{2} \Delta_{D-1} S_D(b, 1) + b^2 \frac{D(3D-1)}{24} \Delta_{D-2} S_D(b, 1), \tag{7A.25}$$

where

$$\begin{aligned} \bar{S}_D(b, 1) &= \sum_{w=1}^{\infty} D \left[e^{-wb} - \frac{D-1}{2} e^{-2wb} + \frac{(D-1)(D-2)}{6} e^{-3wb} \right] \\ &\times \left[\frac{1}{(1-e^{-wb})^D} - \frac{1}{w^D b^D} - \frac{D}{2w^{D-1} b^{D-1}} - \frac{D(3D-1)}{24w^{D-2} b^{D-2}} \right] \end{aligned} \tag{7A.26}$$

is the subtracted sum and

$$\Delta_{D'} S_D(b, 1) \equiv \frac{D}{b^D} \left[\zeta_{D'}(e^{-b}) - \frac{D-1}{2} \zeta_{D'}(e^{-2b}) + \frac{(D-1)(D-2)}{6} \zeta_{D'}(e^{-3b}) \right] \tag{7A.27}$$

collects the remainders. The subtracted sum can now be done in the limit of small b as an integral over w , using the well-known integral formula for the Beta function:

$$\int_0^{\infty} dx \frac{e^{-ax}}{(1-e^{-x})^b} = B(a, 1-b) = \frac{\Gamma(a)\Gamma(1-b)}{\Gamma(1+a-b)}. \tag{7A.28}$$

This yields the small- b contributions to the subtracted sums

$$\begin{aligned} \bar{S}_1(b, 1) &\xrightarrow{b \rightarrow 0} \frac{1}{b} \left(\gamma - \frac{7}{12} \right) \equiv s_1, \\ \bar{S}_2(b, 1) &\xrightarrow{b \rightarrow 0} \frac{1}{b} \left(\gamma + \log 2 - \frac{9}{8} \right) \equiv s_2, \\ \bar{S}_3(b, 1) &\xrightarrow{b \rightarrow 0} \frac{1}{b} \left(\gamma + \log 3 - \frac{19}{24} \right) \equiv s_3, \end{aligned} \tag{7A.29}$$

where $\gamma = 0.5772\dots$ is the Euler-Mascheroni number (2.469). The remaining sum-minus-integral is obtained by a series expansion of $1/(1-e^{-wb})^D$ in powers of b and performing the sums over w using formula (2.584). However, due to the subtractions, the corrections are all small of order $(1/b^D)\mathcal{O}(b^3)$, and will be ignored here. Thus we obtain

$$S_D(b, 1) = \frac{s_D}{b^D} + \Delta S_D(b, 1) + \frac{1}{b^D} \mathcal{O}(b^3). \tag{7A.30}$$

We now expand $\Delta_{D'} S_D(b, 1)$ using Robinson's formula (2.583) up to b^2/b^D and find

$$\begin{aligned} \Delta_{D'} S_1(b, 1) &= \frac{1}{b} \zeta_{D'}(e^{-b}), \\ \Delta_{D'} S_2(b, 1) &= \frac{1}{b^2} [2\zeta_{D'}(e^{-b}) - \zeta_{D'}(e^{-2b})], \\ \Delta_{D'} S_3(b, 1) &= \frac{1}{b^3} [3\zeta_{D'}(e^{-b}) - 3\zeta_{D'}(e^{-2b}) + \zeta_{D'}(e^{-3b})], \end{aligned} \tag{7A.31}$$

$$\tag{7A.32}$$

where

$$\zeta_1(e^{-b}) = -\log(1-e^{-b}) = -\log b + \frac{b}{2} - \frac{b^2}{24} + \dots,$$

$$\zeta_2(e^{-b}) = \zeta(2) + b(\log b - 1) - \frac{b^2}{4} + \dots, \quad (7A.33)$$

$$\zeta_3(e^{-b}) = \zeta(3) - \frac{b}{6}\zeta(2) - \frac{b^2}{2} \left(\log b - \frac{3}{2} \right) + \dots, \quad (7A.34)$$

The results are

$$\begin{aligned} S_1(b, 1) &= \frac{1}{b} \left[(-\log b + \gamma) + \frac{b}{4} - \frac{b^2}{144} + \dots \right], \\ S_2(b, 1) &= \frac{1}{b^2} \left[\zeta(2) - b \left(\log b - \gamma + \frac{1}{2} \right) + \frac{7b^2}{24} + \dots \right], \\ S_3(b, 1) &= \frac{1}{b^3} \left[\zeta(3) + \frac{3b}{2}\zeta(2) - b^2 \left(\log b - \gamma + \frac{19}{24} \right) + \dots \right], \end{aligned} \quad (7A.35)$$

as stated in Eqs. (7.165)–(7.167).

Note that the calculation cannot be shortened by simply expanding the factor $1/(1 - e^{-wb})^D$ in the unsubtracted sum (7A.24) in powers of w , which would yield the result (7A.25) without the first term $\bar{S}_1(b, 1)$, and thus without the integrals (7A.29).

Appendix 7B Experimental versus Theoretical Would-be Critical Temperature

In Fig. 7.12 we have seen that there is only a small difference between the theoretical would-be critical temperature T_c of a finite system calculated from the equation $N = S_2(1)$ and the experimental T_c^{exp} determined from the maximum of the second derivative of the condensate fraction $\rho \equiv N_{\text{cond}}/N$. Let us estimate the difference. The temperature T_c is found by solving the equation [recall (7.90)]

$$N = S_D(1) \equiv \sum_{w=1}^{\infty} [Z_1^D(wb_c) e^{wDb/2} - 1]. \quad (7B.1)$$

To find the latter we must solve the full equation (7A.1) and search for the maximum of $d^2 N_{\text{cond}}(T)/dT^2$. The last term in (7A.1) can be expressed in terms of the condensate fraction $\rho(T)$ as $N_{\text{cond}}(T) = \rho(T)N$. Near the critical point, we set $\delta z_D \equiv 1 - z_D$ and see that it is equal to $\delta z_D = 1/(1 + N\rho)$

In the critical regime, ρ and $1/N\rho$ are both of the same order $1/\sqrt{N}$. Thus we expand $S_D(z_D)$ to lowest order in $\delta z_D = 1/N\rho + \dots$, and replace (7A.1) by

$$N \approx [S_D(1) + \partial_b S_D(1)\delta b - \partial_{z_L} S_D(1)(1/N\rho - 1/N + \dots)] + \rho N, \quad (7B.2)$$

or

$$\frac{b\partial_b S_D(1)}{S_D(1)} \frac{\delta b}{b} \approx \frac{\partial_{z_L} S_D(1)}{S_D(1)} \frac{1}{N\rho} - \rho + \dots, \quad (7B.3)$$

In this leading-order discussion we may ignore the finite-size correction to $S_D(1)$, i.e., the difference between $T_c^{(0)}$ and $T_c^{(1)}$, so that $S_D(1) = (\pi/2b_c^{(0)})^{D/2}$, and we may approximate the left-hand side of (7B.3) by $(D/2)\delta T/T_c^{(0)}$. Abbreviating $\partial_{z_L} S_D(1)/S_D(1)$ by A which is of order unity, we must find $\rho(T)$ from the equation

$$\frac{D}{2}t \approx \frac{A}{N\rho} - \rho - \frac{A}{N}, \quad (7B.4)$$

where $t \equiv \delta T/T_c^{(0)}$. This yields

$$\rho(t) = \sqrt{\frac{A}{N}} - \frac{D}{4}t + \frac{D^2}{32}\sqrt{\frac{N}{A}}t^2 - \frac{D^4}{2048}\sqrt{\frac{N}{A}}t^4 + \dots. \quad (7B.5)$$

The maximum of $d^2\rho(t)/dt^2$ lies at $t = 0$, so that the experimental would-be critical coincides with the theoretical $T_c^{(1)}$ to this order.

If we carry the expansion of (7B.2) to the second order in $\rho \approx 1/N\rho \approx 1/\sqrt{N}$, we find a shift of the order $1/N$. As an example, take $D = 3$, assume $A = 1$, and use the full T -dependence rather than the lowest-order expansion in Eq. (7B.4):

$$\left(\frac{T}{T_c^{(0)}}\right)^{3/2} = (1+t)^{3/2} = \frac{1}{N\rho} - \rho. \quad (7B.6)$$

For simplicity, we ignore the $1/N$ terms in (7B.3). The resulting $\rho(t)$ and $d^2\rho/dt^2$ are plotted in Fig. 7.13. The maximum of $d^2\rho/dt^2$ lies at $t \approx 8/9N$, which can be ignored if we know T_c only up to order $\mathcal{O}(N^{-1/3})$ or $\mathcal{O}(N^{-2/3})$, as in Eqs. (7.91) and (7A.22).

Figure 7.13 Plots of condensate fraction and its second derivative for Bose Gas in a finite box following Eq. (7B.6) for $N = 100$ and 1000 .

Note that a convenient way to determine the would-be critical temperature from numerical data is via the maximal curvature of the chemical potential $\mu(T)$, i.e., from the maximum of $-d^2\mu(T)/dT^2$. Since $z_D = e^{\mu - Db/2} = 1 - \delta z_D \approx 1 + \mu - Db/2$, the second derivative of μ is related to that of δz_D by

$$-\frac{d^2\mu}{dt^2} \approx \frac{d^2\delta z_D}{dt^2} - Db_c^{(0)}. \quad (7B.7)$$

The second term is of the order $1/N^{2/D}$ and can be ignored as we shall see immediately. The equation shows that the second derivative of $-\mu$ coincides with that of δz_D , which is related to $d^2\rho/dt^2$ by

$$\frac{d^2\delta z_D}{dt^2} \approx \frac{d^2}{dt^2} \frac{1}{N\rho} = \frac{1}{N} \left[\frac{2}{\rho^3} \left(\frac{d\rho}{dt}\right)^2 - \frac{1}{\rho^2} \frac{d^2\rho}{dt^2} \right] = \frac{D^2}{16} \sqrt{\frac{N}{A^3}} \left[1 - \frac{3D^2}{32} \frac{N}{A} t^2 + \mathcal{O}(t^4) \right]. \quad (7B.8)$$

This is again maximal at $t = 0$, implying that the determination of $T_c^{(1)}$ by this procedure coincides with the previous one. The neglected term of order $1/N^{2/D}$ has a relative suppression of $1/N^{2/D+1/2}$, which can be ignored for larger N .

Notes and References

Path Integrals in Polar and Spherical Coordinates

Many physical systems possess rotational symmetry. In operator quantum mechanics, this property is of great help in finding wave functions and energies of a system. If a rotationally symmetric Schrödinger equation is transformed to spherical coordinates, it separates into a radial and several angular differential equations. The latter are universal and have well-known solutions. Only the radial equation contains specific information on the dynamics of the system. Being an ordinary one-dimensional Schrödinger equation, it can be solved with the usual techniques.

In the path integral approach, a similar coordinate transformation is possible, although it makes things initially more complicated rather than simpler. First, the use of non-Cartesian coordinates causes nontrivial problems of the kind observed in Chapter 6, where the configuration space was topologically constrained. Such problems can be solved as in Chapter 6 using the knowledge of the correct procedure in Cartesian coordinates. A second complication is more severe: When studying a system at a given angular momentum, the presence of a centrifugal barrier destroys the possibility of setting up a time-sliced path integral of the Feynman type as in Chapter 2. The recent solution of the latter problem has paved the way for two major advances in path integration which will be presented in Chapters 10, 11, and 12.

8.1 Angular Decomposition in Two Dimensions

Consider a two-dimensional quantum-mechanical system with rotational invariance. In Schrödinger quantum mechanics, it is convenient to introduce polar coordinates

$$\mathbf{x} = r(\cos\varphi, \sin\varphi), \quad (8.1)$$

and to split the differential equation into a radial and an azimuthal one which are solved separately. Let us try to follow the same approach in path integrals. To avoid the complications associated with path integrals in the canonical formulation [1], all calculations will be done in the Lagrange formulation. It will, moreover, be advantageous to work with the imaginary-time amplitude (the thermal density

matrix) to avoid carrying around factors of i . Thus we start out with the path integral

$$(\mathbf{x}_b\tau_b|\mathbf{x}_a\tau_a) = \int \mathcal{D}^2x(\tau) \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{\mathbf{x}}^2 + V(r) \right] \right\}. \quad (8.2)$$

It is time-sliced in the standard way into a product of integrals

$$(\mathbf{x}_b\tau_b|\mathbf{x}_a\tau_a) \approx \prod_{n=1}^N \left[\int \frac{d^2x_n}{2\pi\hbar\epsilon/M} \right] \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (\mathbf{x}_n - \mathbf{x}_{n-1})^2 + V(r_n) \right] \right\}. \quad (8.3)$$

When going over to polar coordinates, the measure of integration changes to

$$\prod_{n=1}^N \int_0^\infty dr_n r_n \int_0^{2\pi} \frac{d\varphi_n}{2\pi\hbar\epsilon/M}$$

and the kinetic term becomes

$$\exp \left[-\frac{1}{\hbar} \frac{M}{2\epsilon} (\mathbf{x}_n - \mathbf{x}_{n-1})^2 \right] = \exp \left\{ -\frac{1}{\hbar} \frac{M}{2\epsilon} \left[r_n^2 + r_{n-1}^2 - 2r_n r_{n-1} \cos(\varphi_n - \varphi_{n-1}) \right] \right\}. \quad (8.4)$$

To do the φ_n -integrals, it is useful to expand (8.4) into a factorized series using the formula

$$e^{a\cos\varphi} = \sum_{m=-\infty}^{\infty} I_m(a) e^{im\varphi}, \quad (8.5)$$

where $I_m(z)$ are the modified Bessel functions. Then (8.4) becomes

$$\begin{aligned} & \exp \left[-\frac{1}{\hbar} \frac{M}{2\epsilon} (\mathbf{x}_n - \mathbf{x}_{n-1})^2 \right] \\ &= \exp \left[-\frac{1}{\hbar} \frac{M}{2\epsilon} (r_n^2 + r_{n-1}^2) \right] \sum_{m=-\infty}^{\infty} I_m \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) e^{im(\varphi_n - \varphi_{n-1})}. \end{aligned} \quad (8.6)$$

In the discretized path integral (8.3), there are $N + 1$ factors of this type. The N -integrations over the φ_n -variables can now be performed and produce N Kronecker δ 's:

$$\prod_{n=1}^N 2\pi \delta_{m_n, m_{n-1}}. \quad (8.7)$$

These can be used to eliminate all but one of the sums over m , so that we arrive at the amplitude

$$\begin{aligned} (\mathbf{x}_b\tau_b|\mathbf{x}_a\tau_a) &\approx \frac{2\pi}{2\pi\hbar\epsilon/M} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n r_n 2\pi}{2\pi\hbar\epsilon/M} \right] \sum_{m=-\infty}^{\infty} \frac{1}{2\pi} e^{im(\varphi_b - \varphi_a)} \\ &\times \prod_{n=1}^{N+1} \left\{ \exp \left[-\frac{1}{\hbar} \frac{M}{2\epsilon} (r_n^2 + r_{n-1}^2) \right] I_m \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) \right\} \exp \left[-\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} V(r_n) \right]. \end{aligned} \quad (8.8)$$

We now define the *radial time evolution amplitudes* by the following expansion with respect to the azimuthal quantum numbers m :

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = \sum_{m=-\infty}^{\infty} \frac{1}{\sqrt{r_b r_a}} (r_b \tau_b | r_a \tau_a)_m \frac{1}{2\pi} e^{im(\varphi_b - \varphi_a)}. \quad (8.9)$$

The amplitudes $(r_b \tau_b | r_a \tau_a)_m$ are obviously given by the *radial path integral*

$$\begin{aligned} (r_b \tau_b | r_a \tau_a)_m &\approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \\ &\times \prod_{n=1}^{N+1} \left[\exp \left\{ -\frac{M}{2\epsilon\hbar} (r_n - r_{n-1})^2 \right\} \tilde{I}_m \left(\frac{M r_n r_{n-1}}{\hbar\epsilon} \right) \right] \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} V(r_n) \right\}. \end{aligned} \quad (8.10)$$

Here we have introduced slightly different modified Bessel functions

$$\tilde{I}_m(z) \equiv \sqrt{2\pi z} e^{-z} I_m(z). \quad (8.11)$$

They will also be called ‘‘Bessel functions’’, for short. They have the asymptotic behavior

$$\tilde{I}_m(z) \xrightarrow{z \rightarrow \infty} 1 - \frac{m^2 - 1/4}{2z} + \dots = e^{-\frac{m^2 - 1/4}{2z}} + \dots, \quad (8.12)$$

$$\tilde{I}_m(z) \xrightarrow{z \rightarrow 0} 2\sqrt{\pi} (z/2)^{m+1/2} + \dots. \quad (8.13)$$

In the case of a free particle with $V(r) = 0$, it is easy to perform all the intermediate integrals over r_n in (8.10). Two neighboring figures in the product require the integral

$$\begin{aligned} \int_0^\infty dr' \exp \left(-\frac{r''^2}{2\epsilon_2} - \frac{r^2}{2\epsilon_1} \right) \exp \left[-r'^2 \left(\frac{1}{2\epsilon_2} + \frac{1}{2\epsilon_1} \right) \right] \frac{\sqrt{r'' r'}}{\epsilon_2} I_m \left(\frac{r'' r'}{\epsilon_2} \right) \frac{\sqrt{r' r}}{\epsilon_1} I_m \left(\frac{r' r}{\epsilon_1} \right) \\ = \exp \left[-\frac{r''^2 + r^2}{2(\epsilon_1 + \epsilon_2)} \right] \frac{\sqrt{r'' r}}{\epsilon_1 + \epsilon_2} I_m \left(\frac{r'' r}{\epsilon_1 + \epsilon_2} \right). \end{aligned} \quad (8.14)$$

For simplicity, the units in this formula are $M = 1, \hbar = 1$. The right-hand side of (8.14) follows directly from the formula

$$\int_0^\infty dr r e^{-r^2/\epsilon} I_\nu(\beta r) I_\nu(\alpha r) = \frac{\epsilon}{2} e^{(\alpha^2 + \beta^2)\epsilon/4} I_\nu(\epsilon\alpha\beta/2), \quad (8.15)$$

after identifying ϵ, α, β as

$$\begin{aligned} \epsilon &= 2\epsilon_1\epsilon_2 / (\epsilon_1 + \epsilon_2), \\ \alpha &= r/\epsilon_1, \\ \beta &= r''/\epsilon_2. \end{aligned} \quad (8.16)$$

Thus, the integrals in (8.10) with $V(r) = 0$ can successively be performed yielding the thermal amplitude for $\tau_b > \tau_a$:

$$(r_b \tau_b | r_a \tau_a)_m = \frac{M}{\hbar} \frac{\sqrt{r_b r_a}}{\tau_b - \tau_a} \exp \left[-\frac{M}{2\hbar} \frac{r_b^2 + r_a^2}{\tau_b - \tau_a} \right] I_m \left(\frac{M}{\hbar} \frac{r_b r_a}{\tau_b - \tau_a} \right). \quad (8.17)$$

Note that the same result could have been obtained more directly from the imaginary-time amplitude of a free particle in two dimensions,

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = \frac{M}{2\pi\hbar(\tau_b - \tau_a)} \exp \left[-\frac{M}{2\hbar} \frac{(\mathbf{x}_b - \mathbf{x}_a)^2}{\tau_b - \tau_a} \right], \quad (8.18)$$

by rewriting the right-hand side as

$$\frac{M}{2\pi\hbar(\tau_b - \tau_a)} \exp \left(-\frac{M}{2\hbar} \frac{r_b^2 + r_a^2}{\tau_b - \tau_a} \right) \exp \left[\frac{M}{2\hbar} \frac{r_b r_a}{\tau_b - \tau_a} \cos(\varphi_b - \varphi_a) \right],$$

and expanding the second exponential according to (8.5) into the series

$$\sum_{m=-\infty}^{\infty} I_m \left(\frac{M}{\hbar} \frac{r_b r_a}{\tau_b - \tau_a} \right) e^{im(\varphi_b - \varphi_a)}. \quad (8.19)$$

A comparison of the coefficients with those in (8.9) gives the radial amplitudes (8.17).

Due to (8.14), the radial amplitude satisfies a fundamental composition law corresponding to (2.4), which reads for $\tau_b > \tau > \tau_a$

$$\int_0^{\infty} dr r (r_b \tau_b | r \tau)_m (r \tau | r_a \tau_a)_m = (r_b \tau_b | r_a \tau_a)_m. \quad (8.20)$$

8.2 Trouble with Feynman's Path Integral Formula in Radial Coordinates

In the above calculation we have shown that the expression (8.10) is certainly the correct radial path integral. It is, however, not of the Feynman type. In operator quantum mechanics we learn that the action of a particle moving in a potential $V(r)$ at a fixed angular momentum $L_3 = m\hbar$ contains a centrifugal barrier $\hbar^2(m^2 - 1/4)/2Mr^2$ and reads

$$\mathcal{A}_m = \int_{\tau_a}^{\tau_b} d\tau \left(\frac{M}{2} \dot{r}^2 + \frac{\hbar^2}{2M} \frac{m^2 - 1/4}{r^2} + V(r) \right). \quad (8.21)$$

This is shown by separating the Hamiltonian operator into radial and azimuthal coordinates, over fixing the azimuthal angular momentum L_3 , and choosing for it the quantum-mechanical value $\hbar m$. According to Feynman's rules, the radial amplitude therefore should simply be given by the path integral

$$(r_b \tau_b | r_a \tau_a)_m = \int_0^{\infty} \mathcal{D}r \exp \left(-\frac{1}{\hbar} \mathcal{A}_m \right). \quad (8.22)$$

The reader may object to using the word “classical” in the presence of a term proportional to \hbar^2 in the action. In this section, however, $\hbar m$ is merely meant to be a parameter specifying the azimuthal momentum $p_\varphi \equiv \hbar m$ in the classical centrifugal barrier $p_\varphi^2/2Mr^2$. It is parametrized in terms of a dimensionless number m which does not necessarily have the integer values required by the quantization of the azimuthal motion.

By naively time-slicing (8.22) according to Feynman’s rules of Section 2.1 we would have defined it by the finite- N expression

$$(r_b\tau_b|r_a\tau_a)_m \approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \\ \times \exp \left\{ -\frac{1}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon} (r_n - r_{n-1})^2 + \epsilon \frac{\hbar^2}{2M} \frac{m^2 - 1/4}{r_n r_{n-1}} + \epsilon V(r_n) \right] \right\}. \quad (8.23)$$

Actually, the denominators in the centrifugal barrier could have been chosen to be r_n^2 . This would make a negligible difference for small ϵ . Note that in contrast to a standard Feynman path integral in one dimension, the integrations over r cover only the semi-axis $r \geq 0$ rather than the complete r -axis. This represents no problem since we have learned in Chapter 6 how to treat such half-spaces.

The expression (8.23) is now a place for an unpleasant surprise: For $m = 0$, a time-sliced Feynman path integral formula cannot possibly exist since the potential has an abyss at small r . This leads to a phenomenon which will be referred to as the *path collapse*, to be understood physically and resolved later in Chapter 12. At this place we merely point out the mathematical origin of the problem, by comparing the naively time-sliced expression (8.23) with the certainly correct one (8.10). The singularity would be of no consequence if the two expressions were to converge towards each other in the continuum limit $\epsilon \rightarrow 0$. At first sight, this seems to be the case. After all, ϵ is assumed to be infinitesimally small so that we may replace the “Bessel function” $\tilde{I}_m(Mr_n r_{n-1}/\hbar\epsilon)$ by its asymptotic form (8.12),

$$\tilde{I}_m \left(\frac{Mr_n r_{n-1}}{\hbar\epsilon} \right) \xrightarrow{\epsilon \rightarrow 0} \exp \left(-\epsilon \frac{\hbar}{2M} \frac{m^2 - 1/4}{r_n r_{n-1}} \right). \quad (8.24)$$

For a fixed set of r_n , i.e., for a given path, the continuum limit $\epsilon \rightarrow 0$ makes the integrands (8.10) and (8.23) coincide, the difference being of the order ϵ^2 . Unfortunately, the path integral requires the limit to be taken *after* the integrations over the dr_n . The integrals, however, do not exist at $m = 0$. For paths moving very close to the singularity at $r = 0$, the approximation (8.24) breaks down. In fact, the large- z expansion

$$\tilde{I}_m(z) = 1 - \frac{m^2 - 1/4}{2z} + \frac{(m^2 - 1/4)(m^2 - 1/9)}{2!(2z)^2} - \dots \quad (8.25)$$

with $z = Mr_n r_{n-1}/\hbar\epsilon$ is never convergent even for a very small ϵ . The series shows only an asymptotic convergence (more on this subject in Section 17.9). If we want

to evaluate $\tilde{I}_m(z) = \sqrt{2\pi z} e^{-z} I_m(z)$ for all z we have to use the convergent power series expansion of $I_m(z)$ around $z = 0$:

$$I_m(z) = \left(\frac{z}{2}\right)^m \left[\frac{1}{0!m!} + \frac{1}{1!(m+1)!} \left(\frac{z}{2}\right)^2 + \frac{1}{2!(m+2)!} \left(\frac{z}{2}\right)^4 + \dots \right].$$

It is known from the Schrödinger theory that the leading power z^m determines the threshold behavior of the quantum-mechanical particle distribution near the origin. This is qualitatively different from the exponentially small distribution $\exp[-\epsilon\hbar(m^2 - 1/4)/2Mr^2]$ contained in each time slice of the Feynman formula (8.23) for $|m| > 1/2$.

The root of these troubles is an anomalous behavior in the high-temperature limit of the partition function. In this limit, the imaginary time difference $\tau_b - \tau_a = \hbar/k_B T$ is very small and it is usually sufficient to keep only a single slice in a time-sliced path integral (see Sections 2.9, 2.13). If this were true also here, the formula (8.23) would lead, in the absence of a potential $V(r)$, to the classical particle distribution [compare (2.349)]

$$(r_a \tau_a + \epsilon|r_a \tau_a) = \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \exp\left(-\epsilon \frac{\hbar}{2M} \frac{m^2 - 1/4}{r_a^2}\right). \quad (8.26)$$

If we subtract the barrier-free distribution, this amounts to the classical partition function¹

$$Z_{\text{cl}} = \int_0^\infty \frac{dr}{\sqrt{2\pi a}} \left[\exp\left(-a \frac{m^2 - 1/4}{2r^2}\right) - 1 \right] = -\frac{1}{2} \sqrt{m^2 - \frac{1}{4}}, \quad (8.27)$$

where we have abbreviated the factor $\epsilon\hbar/M$ by a . The integral is temperature-independent and converges only for $|m| > 1/2$.

Compare this result with the proper high-temperature limit of the exact partition function calculated with the use of (8.17) and with the same subtraction as before. It reads for *all* T

$$Z = \frac{1}{2} \int_0^\infty dz e^{-z} [I_m(z) - I_{1/2}(z)]. \quad (8.28)$$

As in the classical expression, there is no temperature dependence. The integral

$$\int_0^\infty dz e^{-\alpha z} I_\mu(z) = (\alpha^2 - 1)^{-1/2} (\alpha + \sqrt{\alpha^2 - 1})^{-\mu} \quad (8.29)$$

[see formula (2.475)] converges for arbitrary real ν and $\alpha > 1$, and gives in the limit $\alpha \rightarrow 1$

$$Z = -\frac{1}{2}(m - 1/2). \quad (8.30)$$

¹This follows by expanding the formula $\int_0^\infty dx e^{-a/x^2 - bx^2} = \sqrt{\pi/4b} e^{-2\sqrt{ab}}$ in powers of \sqrt{b} , subtracting the $a = 0$ -term, and taking the limit $b \rightarrow 0$.

This is different from the classical result (8.27) and agrees with it only in the limit of large m .²

Thus we conclude that a time-sliced path integral containing a centrifugal barrier can only give the correct amplitude when using the Euclidean action

$$\tilde{\mathcal{A}}_m^N = \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon} (r_n - r_{n-1})^2 - \hbar \log \tilde{I}_m \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) \right], \quad (8.31)$$

in which the neighborhood of the singularity is treated quantum-mechanically. The naively time-sliced classical action in (8.23) is of no use. The centrifugal barrier renders therefore a counterexample to Feynman rules of path integration according to which quantum-mechanical amplitudes should be obtainable from a sum over all histories of exponentials which involve only the classical expression for the short-time actions.

It is easy to see where the derivation of the time-sliced path integral in Section 2.1 breaks down. There, the basic ingredient was the Trotter product formula (2.26), which for imaginary time reads

$$e^{-\beta(\hat{T}+\hat{V})} = \lim_{N \rightarrow \infty} \left(e^{-\epsilon\hat{T}} e^{-\epsilon\hat{V}} \right)^{N+1}, \quad \epsilon \equiv \beta/(N+1). \quad (8.32)$$

An exact identity is $e^{-\beta(\hat{T}+\hat{V})} \equiv \left(e^{-\epsilon\hat{T}} e^{-\epsilon\hat{V}} e^{i\epsilon^2 X} \right)^{N+1}$ with X given in Eq. (2.10) consisting of a sum of higher and higher commutators between \hat{V} and \hat{T} . The Trotter formula neglects these commutators. In the presence of a centrifugal barrier, however, this is not permitted. Although the neglected commutators carry increasing powers of the small quantity ϵ , they are more and more divergent at $r = 0$, like $\epsilon^n/r^{2\pi}$. The same terms occur in the asymptotic expansion (8.25) of the ‘‘Bessel function’’. In the proper action (8.31), these terms are present.

It should be noted that for a Hamiltonian possessing a centrifugal barrier V_{cb} in addition to an arbitrary smooth potential V , i.e., for a Hamiltonian operator of the form $\hat{H} = \hat{T} + \hat{V}_{\text{cf}} + \hat{V}$, the Trotter formula is applicable in the form

$$e^{-\beta H} = \lim_{N \rightarrow \infty} \left(e^{-\epsilon(\hat{T}+\hat{V}_{\text{cb}})} e^{-\epsilon\hat{V}} \right)^{N+1}, \quad \epsilon \equiv \beta/(N+1). \quad (8.33)$$

It leads to a valid time-sliced path integral formula

$$(r_b \tau_b | r_a \tau_a)_m \approx \prod_{n=1}^N \left[\int_0^\infty dr_n \right] \prod_{n=1}^{N+1} \left[\int \frac{dp_n}{2\pi\hbar} \right] \exp \left\{ -\frac{1}{\hbar} \tilde{\mathcal{A}}_m^N[p, r] \right\}, \quad (8.34)$$

with the sliced action

$$\tilde{\mathcal{A}}_m^N[p, r] = \sum_{n=1}^{N+1} \left[-ip_n(r_n - r_{n-1}) + \epsilon \frac{p_n^2}{2M} - \hbar \log \tilde{I}_m \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) + \epsilon V(r_n) \right]. \quad (8.35)$$

²If m were not merely a dimensionless number parametrizing an arbitrary centrifugal barrier with fixed $p_\varphi^2/2Mr^2$, as it is in this section, the classical limit at a fixed p_φ would eliminate the problem since for $\hbar \rightarrow 0$, the number m would become infinitely large, leading to the correct high-temperature limit of the partition function. For a fixed finite m , however, the discrepancy is unavoidable.

After integrating out the momenta, this becomes

$$(r_b\tau_b|r_a\tau_a)_m \approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \exp \left\{ -\frac{1}{\hbar} \tilde{\mathcal{A}}_m^N[r] \right\}, \quad (8.36)$$

with the action

$$\tilde{A}_m^N[r, \dot{r}] = \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon} (r_n - r_{n-1})^2 - \hbar \log \tilde{I}_m \left(\frac{Mr_n r_{n-1}}{\hbar\epsilon} \right) + \epsilon V(r_n) \right]. \quad (8.37)$$

The path integral formula (8.36) can in principle be used to find the amplitude for a fixed angular momentum of some solvable systems.

An example is the radial harmonic oscillator at an angular momentum m , although it should be noted that this particularly simple example does not really require calculating the integrals in (8.36). The result can be found much more simply from a direct angular momentum decomposition of the amplitude (2.177). After a continuation to imaginary times $t = -i\tau$ and an expansion of part of the exponent with the help of (8.5), it reads for $D = 2$

$$\begin{aligned} (\mathbf{x}_b\tau_b|\mathbf{x}_a\tau_a) &= \frac{1}{2\pi} \frac{M\omega}{\hbar \sinh[\omega(\tau_b - \tau_a)]} e^{-\frac{M\omega}{2\hbar} \coth[\omega(\tau_b - \tau_a)](r_b^2 + r_a^2)} \\ &\quad \times \sum_{m=-\infty}^{\infty} I_m \left(\frac{M\omega r_b r_a}{\hbar \sinh[\omega(\tau_b - \tau_a)]} \right) e^{im(\varphi_b - \varphi_a)}. \end{aligned} \quad (8.38)$$

By comparison with (8.9), we extract the radial amplitude

$$(r_b\tau_b|r_a\tau_a)_m = \frac{M}{\hbar} \frac{\omega \sqrt{r_b r_a}}{\coth[\omega(\tau_b - \tau_a)]} I_m \left(\frac{M\omega r_b r_a}{\hbar \sinh[\omega(\tau_b - \tau_a)]} \right). \quad (8.39)$$

The limit $\omega \rightarrow 0$ gives the free-particle result

$$(r_b\tau_b|r_a\tau_a)_m = \frac{M}{\hbar} \frac{\sqrt{r_b r_a}}{\tau_b - \tau_a} I_m \left(\frac{M}{\hbar} \frac{r_b r_a}{\tau_b - \tau_a} \right). \quad (8.40)$$

8.3 Cautionary Remarks

It is important to emphasize that we obtained the correct amplitudes by performing the time slicing in Cartesian coordinates followed by the transformation to the polar coordinates in the time-sliced expression. Otherwise we would have easily missed the factor $-1/4$ in the centrifugal barrier. To see what can go wrong let us proceed illegally and do the change of variables in the initial continuous action. Thus we try to calculate the path integral

$$\begin{aligned} (\mathbf{x}_b\tau_b|\mathbf{x}_a\tau_a) &= \sum_{l=-\infty, \infty} \int_0^\infty \mathcal{D}r r \int_{-\infty}^\infty \mathcal{D}\varphi \\ &\quad \times \exp \left\{ \frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} (\dot{r}^2 + r^2 \dot{\varphi}^2) + V(r) \right] \right\} \Big|_{\varphi(\tau_b) = \varphi_b + 2\pi l}. \end{aligned} \quad (8.41)$$

The summation over all periodic repetitions of the final azimuthal angle φ accounts for its multivaluedness according to the rules of Section 6.1. If the expression (8.41) is time-sliced straightforwardly it reads

$$\sum_{\varphi_{N+1}=\varphi_b+2\pi l, l=-\infty, \infty} \frac{1}{2\pi\hbar\epsilon/M} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n r_n}{\sqrt{2\pi\hbar\epsilon/M}} \int_{-\infty}^\infty \frac{d\varphi_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \\ \times \exp \left\{ -\frac{1}{\hbar} \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} [(r_n - r_{n-1})^2 + r_n^2 (\varphi_n - \varphi_{n-1})^2] + V(r_n) \right] \right\}, \quad (8.42)$$

where $r_b = r_{N+1}$, $\varphi_a = \varphi_0$, $r_a = r_0$. The integrals can be treated as follows. We introduce the momentum integrals over $(p_\varphi)_n$ conjugate to φ_n , writing for each n [with the short notation $(p_\varphi)_n \equiv p_n$]

$$\frac{r_n}{\sqrt{2\pi\hbar\epsilon/M}} e^{-(M/2\hbar\epsilon)r_n^2(\varphi_n - \varphi_{n-1})^2} = \int_{-\infty}^\infty \frac{dp_n}{2\pi\hbar} \exp \left\{ -\frac{1}{\hbar} \frac{\epsilon}{2M} \frac{p_n^2}{r_n^2} + \frac{i}{\hbar} p_n (\varphi_n - \varphi_{n-1}) \right\}. \quad (8.43)$$

After this, the integrals over φ_n ($n = 1 \dots N$) in (8.42) enforce all p_n to be equal to each other, i.e., $p_n \equiv p$ for $n = 1, \dots, N+1$, and we remain with

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) \approx \frac{1}{2\pi\hbar\epsilon/M} \frac{1}{r_b} \sum_{l=-\infty}^\infty \int_{-\infty}^\infty \frac{dp}{2\pi\hbar} e^{(i/\hbar)p(\varphi_b - \varphi_a + 2\pi l)} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{2\pi\hbar\epsilon/M} \right] \\ \times \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2} \frac{(r_n - r_{n-1})^2}{\epsilon^2} + \frac{p^2}{2Mr_n^2} + V(r_n) \right] \right\}. \quad (8.44)$$

Performing the sum over l with the help of Poisson's formula (6.9) changes the integral over $dp/2\pi\hbar$ into a sum over integers m and yields the angular momentum decomposition (8.9) with the partial-wave amplitudes

$$(r_b \tau_b | r_a \tau_a)_m \approx \sqrt{r_b r_a} \frac{1}{2\pi\hbar\epsilon/M} \frac{1}{r_b} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{2\pi\hbar\epsilon/M} \right] \\ \times \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2} \frac{(r_n - r_{n-1})^2}{\epsilon^2} + \frac{\hbar^2}{2M} \frac{m^2}{r_n^2} + V(r_n) \right] \right\}. \quad (8.45)$$

This wrong result differs from the correct one in Eq. (8.10) in three respects. First, it does not possess the proper centrifugal term $-\hbar \log \tilde{I}_m(Mr_b r_a / \hbar\epsilon)$. Second, there is a spurious overall factor $\sqrt{r_a/r_b}$. Third, in comparison with the limiting expression (8.24), the centrifugal barrier lacks the term $1/4$.

It is possible to restore the term $1/4$ by observing that in the time-sliced expression, the factor $\sqrt{r_b/r_a}$ is equal to

$$\prod_{n=1}^{N+1} \sqrt{\frac{r_b}{r_a}} = \prod_{n=1}^{N+1} \left(1 + \frac{r_n - r_{n-1}}{r_{n-1}} \right)^{-1/2} = \prod_{n=1}^{N+1} \left(1 - \frac{1}{2} \frac{r_n - r_{n-1}}{\sqrt{r_n r_{n-1}}} + \frac{1}{8} \frac{(r_n - r_{n-1})^2}{r_n r_{n-1}} - \dots \right)$$

$$= \exp \left(-\frac{1}{2} \sum_{n=1}^{N+1} \frac{r_n - r_{n-1}}{\sqrt{r_n r_{n-1}}} + \dots \right). \quad (8.46)$$

This, in turn, can be incorporated into the kinetic term of (8.45) via a quadratic completion leading to

$$\exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2} \left(\frac{r_n - r_{n-1}}{\epsilon} + i \frac{\hbar}{2M \sqrt{r_n r_{n-1}}} \right)^2 + \frac{\hbar^2}{2M} \frac{m^2 - 1/4}{r_n^2} \right] \right\}. \quad (8.47)$$

The centrifugal barrier is now correct, but the kinetic term is wrong. In fact, it does not even correspond to a Hermitian Hamiltonian operator, as can be seen by introducing momentum integrations and completing the square to

$$\exp \left\{ -ip_n(r_n - r_{n-1}) + \frac{\epsilon}{\hbar} \left[\frac{p_n^2}{2M} - i\hbar \frac{p_n}{2Mr_n} \right] \right\}. \quad (8.48)$$

The last term is an imaginary energy. Only by dropping it artificially would the time-sliced action acquire the Feynman form (8.23), while still being beset with the problem of nonexistence for $m = 0$ (path collapse) and the nonuniform convergence of the path integrations to be solved in Chapter 12.

The lesson of this is the following: A naive time slicing *cannot* be performed in curvilinear coordinates. It can safely be done in the Cartesian formulation.

Fortunately, a systematic modification of the naive slicing rules has recently been found which makes them applicable to non-Cartesian systems. This will be shown in Chapters 10 and 11.

In the sequel it is useful to maintain, as far as possible, the naive notation for the radial path integral (8.23) and the continuum limit of the action (8.21). The places where care has to be taken in the time-slicing process will be emphasized by setting the centrifugal barrier in quotation marks and defining

$$\epsilon \frac{\hbar^2}{2M} \frac{m^2 - 1/4}{r_n r_{n-1}} \equiv -\hbar \log \tilde{I}_m \left(\frac{Mr_n r_{n-1}}{\hbar \epsilon} \right). \quad (8.49)$$

Thus we shall write the properly sliced action (8.37) as

$$\tilde{A}_m^N[r, \dot{r}] = \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon} (r_n - r_{n-1})^2 + \epsilon \frac{\hbar^2}{2\mu} \frac{m^2 - 1/4}{r_n r_{n-1}} + \epsilon V(r_n) \right], \quad (8.50)$$

and emphasize the need for the non-naive time slicing of the continuum action correspondingly:

$$\mathcal{A}_m = \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{r}^2 + \frac{\hbar^2}{2M} \frac{m^2 - 1/4}{r^2} + V(r) \right]. \quad (8.51)$$

8.4 Time Slicing Corrections

It is interesting to find the origin of the above difficulties. For this purpose, we take the Cartesian kinetic terms expressed in terms of polar coordinates

$$(\mathbf{x}_n - \mathbf{x}_{n-1})^2 = (r_n - r_{n-1})^2 + 2r_n r_{n-1} [1 - \cos(\varphi_n - \varphi_{n-1})], \quad (8.52)$$

and treat it perturbatively in the coordinate differences [2]. Expanding the cosine into a power series we obtain the time-sliced action

$$\begin{aligned} \mathcal{A}^N = \frac{M}{2\epsilon} \sum_{n=1}^{N+1} (\mathbf{x}_n - \mathbf{x}_{n-1})^2 = \frac{M}{2\epsilon} \sum_{n=1}^{N+1} \left\{ (r_n - r_{n-1})^2 \right. \\ \left. + 2r_n r_{n-1} \left[\frac{1}{2!} (\varphi_n - \varphi_{n-1})^2 - \frac{1}{4!} (\varphi_n - \varphi_{n-1})^4 + \dots \right] \right\}. \end{aligned} \quad (8.53)$$

In contrast to the naively time-sliced expression (8.42), we now keep the quartic term $(\varphi_n - \varphi_{n-1})^4$. To see how it contributes, consider a single intermediate integral

$$\int \frac{d\varphi_{n-1}}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)[(\varphi_n - \varphi_{n-1})^2 + a_4(\varphi_n - \varphi_{n-1})^4 + \dots]}. \quad (8.54)$$

The first term in the exponent restricts the width of the fluctuations of the difference $\varphi_n - \varphi_{n-1}$ to

$$\langle (\varphi_n - \varphi_{n-1})^2 \rangle_0 = \frac{\epsilon}{a}. \quad (8.55)$$

If we rescale the arguments, $\varphi_n \rightarrow \sqrt{\epsilon} u_n$, the integral takes the form

$$\int \frac{du_{n-1}}{\sqrt{2\pi/a}} e^{-(a/2)[(u_n - u_{n-1})^2 + \epsilon a_4 (u_n - u_{n-1})^4 + \dots]}. \quad (8.56)$$

This shows that each higher power in the difference $u_n - u_{n-1}$ is suppressed by an additional factor $\sqrt{\epsilon}$. We now expand the integrand in powers of $\sqrt{\epsilon}$ and use the integrals

$$\int \frac{du}{\sqrt{2\pi/a}} e^{-(a/2)u^2} \begin{Bmatrix} u^2 \\ u^4 \\ \vdots \\ u^{2n} \end{Bmatrix} = \begin{Bmatrix} a^{-1} \\ 3a^{-2} \\ \vdots \\ (2n-1)!! a^{-n} \end{Bmatrix}, \quad (8.57)$$

with odd powers of u giving trivially 0, to find an expansion of the integral (8.56). It begins as follows:

$$1 - \epsilon \frac{a}{2} a_4 3a^{-2} + \mathcal{O}(\epsilon^2). \quad (8.58)$$

This can be thought of as coming from the equivalent integral

$$\int \frac{d\varphi_{n-1}}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)(\varphi_n - \varphi_{n-1})^2 - 3a_4\epsilon/2a + \dots}. \quad (8.59)$$

The quartic term in (8.54),

$$\Delta A = \frac{a}{2\epsilon} a_4 (\varphi_n - \varphi_{n-1})^4, \quad (8.60)$$

has generated an effective action-like term in the exponent:

$$A_{\text{eff}} = \epsilon \frac{3a_4}{2a}. \quad (8.61)$$

This is obviously due to the expectation value $\langle \Delta A \rangle_0$ of the quartic term and we can record, for later use, the perturbative formula

$$A_{\text{eff}} = \langle \Delta A \rangle_0. \quad (8.62)$$

If u is a vector in D dimensions to be denoted by \mathbf{u} , with the quadratic term being $(a/2\epsilon)(\mathbf{u}_n - \mathbf{u}_{n-1})^2$, the integrals (8.57) are replaced by

$$\int \frac{d^D u}{\sqrt{2\pi/a}} e^{-(a/2)\mathbf{u}^2} \left\{ \begin{array}{c} u_i u_j \\ u_i u_j u_k u_l \\ \vdots \\ u_{i_1} \cdots u_{i_{2n}} \end{array} \right\} = \left\{ \begin{array}{c} a^{-1} \delta_{ij} \\ a^{-2} (\delta_{ij} \delta_{kl} + \delta_{ik} \delta_{jl} + \delta_{il} \delta_{jk}) \\ \vdots \\ a^{-n} \delta_{i_1 \dots i_{2n}} \end{array} \right\}, \quad (8.63)$$

where $\delta_{i_1 \dots i_{2n}}$ will be referred to as *contraction tensors*, defined recursively by the relation

$$\delta_{i_1 \dots i_{2n}} = \delta_{i_1 i_2} \delta_{i_3 i_4 \dots i_{2n}} + \delta_{i_1 i_3} \delta_{i_2 i_4 \dots i_{2n}} + \dots + \delta_{i_1 i_{2n}} \delta_{i_2 i_3 \dots i_{2n-1}}. \quad (8.64)$$

A comparison with the Wick expansion (3.306) shows that this recursion relation amounts to $\delta_{i_1 \dots i_{2n}}$ possessing a Wick-like expansion into the sum of products of Kronecker δ 's, each representing a pair contraction. Indeed, the integral formulas (8.63) can be derived by adding a source term $\mathbf{j} \cdot \mathbf{u}$ to the exponent in the integrand, completing the square, and differentiating the resulting $e^{(1/2a)\mathbf{j}^2}$ with respect to the "current" components j_i . For vectors φ_i , a possible quartic term in the exponent of (8.54) may have the form

$$\Delta A = \frac{a}{2\epsilon} (a_4)_{ijkl} (\varphi_n - \varphi_{n-1})_i (\varphi_n - \varphi_{n-1})_j (\varphi_n - \varphi_{n-1})_k (\varphi_n - \varphi_{n-1})_l. \quad (8.65)$$

Then the factor $3a_4$ in A_{eff} of Eq. (8.61) is replaced by the three contractions

$$(a_4)_{ijkl} (\delta_{ij} \delta_{kl} + 2 \text{ more pair terms}).$$

Applying the simple result (8.61) to the action (8.53), where $a = (M/\hbar)2r_n r_{n-1}$ and $a_4 = -1/4!$, we find that the naively time-sliced kinetic term of the φ field

$$\frac{M}{2\epsilon} r_n r_{n-1} (\varphi_n - \varphi_{n-1})^2$$

is extended to

$$\frac{M}{2\epsilon} r_n r_{n-1} (\varphi_n - \varphi_{n-1})^2 - \epsilon \hbar^2 \frac{1/4}{2M r_n r_{n-1}} + \dots$$

Thus, the lowest perturbative correction due to the fourth-order expansion term of $\cos(\varphi_n - \varphi_{n-1})$ supplies precisely the $1/4$ -term in the centrifugal barrier which was missing in (8.45). Proceeding in this fashion, the higher powers in the expansion of $\cos(\varphi_n - \varphi_{n-1})$ give higher and higher contributions $(\epsilon/r_n r_{n-1})^n$. Eventually, they would of course produce the entire asymptotic expansion of the ‘‘Bessel function’’ in the correct time-sliced action (8.37).

Note that the failure of this series to converge destroys the justification for truncating the perturbation series after any finite number of terms. In particular, the knowledge of the large-order behavior (the ‘‘tail end’’ of the series) [3] is needed to recover the correct threshold behavior $\propto r^m$ in the amplitudes observed in (8.26).

The reader may rightfully object that the integral (8.56) should really contain an exponential factor $\exp[-(a/2)(u_{n-1} - u_{n-2})^2]$ from the adjacent time slice which also contains the variable u_{n-1} and which has been ignored in the integral (8.56) over u_{n-1} . In fact, with the abbreviations $\bar{u}_{n-1} \equiv (u_n + u_{n-2})/2$, $\delta \equiv u_{n-1} - \bar{u}_{n-1}$, $\Delta \equiv u_n - u_{n-2}$, the complete integrand containing the variable u_{n-1} can be written as

$$\int \frac{d\delta}{\sqrt{2\pi/a}} e^{-a\delta^2} e^{-a\Delta^2/4} \left\{ 1 - \frac{a}{2} \epsilon a_4 [(-\delta + \Delta/2)^4 + (\delta + \Delta/2)^4] + \dots \right\}. \quad (8.66)$$

When doing the integral over δ , each even power δ^{2n} gives a factor $(1/2a)(2n - 1)!!$ and we observe that the mean value of the fluctuating u_{n-1} is different from what it was above, when we singled out the expression (8.56) and ignored the u_{n-1} dependence of the adjacent integral. Instead of u_n in (8.56), the mean value of u_{n-1} is now the average position of the neighbors, $\bar{u}_{n-1} = (u_n + u_{n-2})/2$. Moreover, instead of the width of the u_{n-1} fluctuations being $\langle (u_n - \bar{u}_{n-1})^2 \rangle_0 \sim 1/a$, as in (8.55), it is now given by half this value:

$$\langle (u_{n-1} - \bar{u}_{n-1})^2 \rangle_0 = \frac{1}{2a}. \quad (8.67)$$

At first, these observations seem to invalidate the above perturbative evaluation of (8.56). Fortunately, this objection ignores an important fact which cancels the apparent mistake, and the result (8.62) of the sloppy derivation is correct after all. The argument goes as follows: The integrand of a single time slice is a sharply peaked function of the coordinate difference whose width is of the order ϵ and goes to zero in the continuum limit. If such a function is integrated together with some *smooth* amplitude, it is sensitive only to a small neighborhood of a point in the amplitude. The sharply peaked function is a would-be δ -function that can be effectively replaced by a δ -function plus correction terms which contain increasing derivatives of δ -functions multiplied by corresponding powers of $\sqrt{\epsilon}$. Indeed, let us take the integrand of the model integral (8.54),

$$\frac{1}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)[(\varphi_n - \varphi_{n-1})^2 + a_4(\varphi_n - \varphi_{n-1})^4 + \dots]}, \quad (8.68)$$

and integrate it over φ_{n-1} together with a smooth amplitude $\psi(\varphi_{n-1})$ which plays the same role of a test function in mathematics [recall Eq. (1.162)]:

$$\int_{-\infty}^{\infty} \frac{d\varphi_{n-1}}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)[(\varphi_n - \varphi_{n-1})^2 + a_4(\varphi_n - \varphi_{n-1})^4 + \dots]} \psi(\varphi_{n-1}). \quad (8.69)$$

For small ϵ , we expand $\psi(\varphi_{n-1})$ around φ_n ,

$$\psi(\varphi_{n-1}) = \psi(\varphi_n) - (\varphi_n - \varphi_{n-1})\psi'(\varphi_n) + \frac{1}{2}(\varphi_n - \varphi_{n-1})^2\psi''(\varphi_n) + \dots, \quad (8.70)$$

and (8.69) becomes

$$(1 - A_{\text{eff}})\psi(\varphi_n) + \frac{\epsilon}{2a}\psi''(\varphi_n) + \dots. \quad (8.71)$$

This shows that the amplitude for a single time slice, when integrated together with a smooth amplitude, can be expanded into a series consisting of a δ -function and its derivatives:

$$\begin{aligned} & \frac{1}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)[(\varphi_n - \varphi_{n-1})^2 + a_4(\varphi_n - \varphi_{n-1})^4 + \dots]} \\ &= (1 - A_{\text{eff}})\delta(\varphi_n - \varphi_{n-1}) + \frac{\epsilon}{2a}\delta''(\varphi_n - \varphi_{n-1}) + \dots. \end{aligned} \quad (8.72)$$

The right-hand side may be viewed as the result of a simpler would-be δ -function

$$\frac{1}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)(\varphi_n - \varphi_{n-1})^2} e^{-A_{\text{eff}}}, \quad (8.73)$$

correct up to terms of order ϵ . This is precisely what we found in (8.59).

The problems observed above arise only if the would-be δ -function in (8.72) is integrated together with another sharply peaked neighbor function which is itself a would-be δ -function. Indeed, in the theory of distributions, it is strictly forbidden to form integrals over products of two proper distributions. For the would-be distributions at hand the rule is not quite as strict and integrals over products can be formed. The crucial expansion (8.72), however, is no longer applicable if the accompanying function is a would-be δ -function, and a more careful treatment is required.

The correctness of formula (8.62) derives from the fact that each time slice has, for sufficiently small ϵ , a large number of neighbors at earlier and later times. If the integrals are done for all these neighbors, they render a smooth amplitude before and a smooth amplitude after the slice under consideration. Thus, each intermediate integral in the time-sliced product contains a would-be δ -function multiplied on the right- and left-hand side with a *smooth* amplitude. In each such integral, the replacement (8.59) and thus formula (8.62) is correct. The only exceptions are time

slices near the endpoints. Their integrals possess the above subtleties. The relative number of these, however, goes to zero in the continuum limit $\epsilon \rightarrow 0$. Hence they do not change the final result (8.62).

For completeness, let us state that the presence of a cubic term in the single-sliced action (8.68) has the following δ -function expansion

$$\begin{aligned} & \frac{1}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)[(\varphi_n - \varphi_{n-1})^2 + a_3(\varphi_n - \varphi_{n-1})^3 + a_4(\varphi_n - \varphi_{n-1})^4 + \dots]} \\ &= (1 - A_{\text{eff}})\delta(\varphi_n - \varphi_{n-1}) + 3a_3 \frac{\epsilon}{2a} \delta'(\varphi_n - \varphi_{n-1}) + \frac{\epsilon}{2a} \delta''(\varphi_n - \varphi_{n-1}) + \dots \end{aligned} \quad (8.74)$$

corresponding to an “effective action”

$$A_{\text{eff}} = \frac{\epsilon}{2a} \left[3a_4 - \frac{15}{4}a_3^2 \right]. \quad (8.75)$$

Using (8.75), the left-hand side of (8.74) can also be replaced by the would-be δ -function

$$\frac{1}{\sqrt{2\pi\epsilon/a}} e^{-(a/2\epsilon)(\varphi_n - \varphi_{n-1})^2} e^{-A_{\text{eff}}} \left[1 - \frac{3a_3}{2}(\varphi_n - \varphi_{n-1}) + \dots \right], \quad (8.76)$$

which has the same leading terms in the δ -function expansion.

In D dimensions, the term $3a_3(\varphi_n - \varphi_{n-1})$ has the general form

$$[(a_3)_{ijj} + (a_3)_{jij} + (a_3)_{jji}](\varphi_n - \varphi_{n-1})_i,$$

and the term $15a_3^2$ in A_{eff} becomes

$$(a_3)_{ijk}(a_3)_{i'j'k'}(\delta_{ii'}\delta_{jj'}\delta_{kk'} + 14 \text{ more pair terms}).$$

8.5 Angular Decomposition in Three and More Dimensions

Let us now extend the two-dimensional development of Section 8.2 and study the radial path integrals of particles moving in three and more dimensions. Consider the amplitude for a rotationally invariant action in D dimensions

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = \int \mathcal{D}^D x(\tau) \exp \left\{ -\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} \left[\frac{M}{2} \dot{\mathbf{x}}^2 + V(r) \right] \right\}. \quad (8.77)$$

By time-slicing this in Cartesian coordinates, the kinetic term gives an integrand

$$\exp \left[-\frac{1}{\hbar} \frac{M}{2\epsilon} \sum_{n=1}^{N+1} (r_n^2 + r_{n-1}^2 - 2r_n r_{n-1} \cos \Delta\vartheta_n) \right], \quad (8.78)$$

where $\Delta\vartheta_n$ is the relative angle between the vectors \mathbf{x}_n and \mathbf{x}_{n-1} .

8.5.1 Three Dimensions

In three dimensions, we go over to the spherical coordinates

$$\mathbf{x} = r(\cos \theta \cos \varphi, \cos \theta \sin \varphi, \sin \theta) \quad (8.79)$$

and write

$$\cos \Delta\vartheta_n = \cos \theta_n \cos \theta_{n-1} + \sin \theta_n \sin \theta_{n-1} \cos(\varphi_n - \varphi_{n-1}). \quad (8.80)$$

The integration measure in the time-sliced version of (8.77),

$$\frac{1}{\sqrt{2\pi\hbar\epsilon/M}^3} \prod_{n=1}^N \int \frac{d^3x_n}{\sqrt{2\pi\hbar\epsilon/M}^3}, \quad (8.81)$$

becomes

$$\frac{1}{\sqrt{2\pi\hbar\epsilon/M}^3} \prod_{n=1}^N \int \frac{dr_n r_n^2 d\cos\theta_n d\varphi_n}{\sqrt{2\pi\hbar\epsilon/M}^3}. \quad (8.82)$$

To perform the integrals, we use the spherical analog of the expansion (8.5)

$$e^{h \cos \Delta\vartheta_n} = \sqrt{\frac{\pi}{2h}} \sum_{l=0}^{\infty} I_{l+1/2}(h) (2l+1) P_l(\cos \Delta\vartheta_n), \quad (8.83)$$

where $P_l(z)$ are the Legendre polynomials. These, in turn, can be decomposed into spherical harmonics

$$Y_{lm}(\theta, \varphi) = (-1)^m \left[\frac{2l+1}{4\pi} \frac{(l-m)!}{(l+m)!} \right]^{1/2} P_l^m(\cos \theta) e^{im\varphi}, \quad (8.84)$$

with the help of the addition theorem

$$\frac{2l+1}{4\pi} P_l(\cos \Delta\vartheta_n) = \sum_{m=-l}^l Y_{lm}(\theta_n, \varphi_n) Y_{lm}^*(\theta_{n-1}, \varphi_{n-1}), \quad (8.85)$$

the sum running over all azimuthal (magnetic) quantum numbers m . The right-hand side of $P_l^m(z)$ contains the associated Legendre polynomials

$$P_l^m(z) = \frac{(1-z^2)^{m/2} (l-m)!}{2^l l! (l+m)!} \frac{d^{l+m}}{dz^{l+m}} (z^2-1)^l, \quad (8.86)$$

which are solutions of the differential equation³

$$\left[-\frac{1}{\sin \theta} \frac{d}{d\theta} \left(\sin \theta \frac{d}{d\theta} \right) + \frac{m^2}{\sin^2 \theta} \right] P_l^m(\cos \theta) = l(l+1) P_l^m(\cos \theta). \quad (8.87)$$

³Note that $y_l^m(\cos \theta) = \sqrt{\sin \theta} P_l^m(\cos \theta)$ satisfies $\left[-\frac{d^2}{d\theta^2} - \frac{1}{4} + \frac{m^2 - 1/4}{\sin^2 \theta} \right] y_l^m = l(l+1) y_l^m$. This differential equation will be used later in Eq. (8.197).

Thus, the expansion (8.83) becomes

$$e^{h \cos \Delta \vartheta_n} = \sqrt{\frac{\pi}{2\hbar}} 4\pi \sum_{l=0}^{\infty} I_{l+1/2}(h) \sum_{m=-l}^l Y_{lm}(\theta_n, \varphi_n) Y_{lm}^*(\theta_{n-1}, \varphi_{n-1}). \quad (8.88)$$

Inserted into (8.78), it leads to the time-sliced path integral

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &\approx \frac{4\pi}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n r_n^2 d \cos \theta_n d \varphi_n 4\pi}{\sqrt{2\pi\hbar\epsilon/M}^3} \right] \\ &\times \prod_{n=1}^{N+1} \left[\left(\frac{\hbar\epsilon\pi}{2Mr_n r_{n-1}} \right)^{1/2} \sum_{l_n=0}^{\infty} \sum_{m_n=-l_n}^{l_n} I_{l_n+1/2} \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) \right. \\ &\left. \times Y_{l_n m_n}(\theta_n, \varphi_n) Y_{l_n m_n}^*(\theta_{n-1}, \varphi_{n-1}) \right] \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2} \frac{r_n^2 + r_{n-1}^2}{\epsilon^2} + V(r_n) \right] \right\}. \quad (8.89) \end{aligned}$$

The intermediate φ_n - and $\cos \theta_n$ -integrals can now all be done using the orthogonality relation

$$\int_{-1}^1 d \cos \theta \int_{-\pi}^{\pi} d \varphi Y_{lm}^*(\theta, \varphi) Y_{l'm'}(\theta, \varphi) = \delta_{ll'} \delta_{mm'}. \quad (8.90)$$

Each φ_n -integral yields a product of Kronecker symbols $\delta_{l_n l_{n-1}} \delta_{m_n m_{n-1}}$. Only the initial and the final spherical harmonics survive, $Y_{l_{N+1} m_{N+1}}$ and $Y_{l_0 m_0}^*$, since they are not subject to integration. Thus we arrive at the angular momentum decomposition

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = \sum_{l=0}^{\infty} \sum_{m=-l}^l \frac{1}{r_b r_a} (r_b \tau_b | r_a \tau_a)_l Y_{lm}(\theta_b, \varphi_b) Y_{lm}^*(\theta_a, \varphi_a), \quad (8.91)$$

with the radial amplitude

$$\begin{aligned} (r_b \tau_b | r_a \tau_a)_l &\approx \frac{4\pi r_b r_a}{\sqrt{2\pi\hbar\epsilon/M}^3} \prod_{n=1}^N \left[\int \frac{dr_n r_n^2 4\pi}{\sqrt{2\pi\hbar\epsilon/M}^3} \right] \prod_{n=1}^{N+1} \left[\frac{\hbar\epsilon}{2Mr_n r_{n-1}} \right] \\ &\times \prod_{n=1}^{N+1} \left[\tilde{I}_{l+1/2} \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) \right] \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (r_n - r_{n-1})^2 + V(r_n) \right] \right\}. \quad (8.92) \end{aligned}$$

The factors $\prod_a^N r_n^2 / \prod_a^{N+1} r_n r_{n-1}$ pile up to $1/r_b r_a$ and cancel the prefactor $r_b r_a$. Together with the remaining product, the integration measure takes the usual one-dimensional form

$$\frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right]. \quad (8.93)$$

If we were to use here the large-argument limit (8.24) of the Bessel function, the integrand would become $\exp(-\mathcal{A}_l^N/\hbar)$, with the time-sliced radial action

$$\mathcal{A}_l^N = \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (r_n - r_{n-1})^2 + \frac{\hbar^2}{2M} \frac{l(l+1)}{r_n r_{n-1}} + V(r_n) \right]. \quad (8.94)$$

The associated radial path integral

$$(r_b \tau_b | r_a \tau_a)_l \approx \frac{1}{\sqrt{2\pi\epsilon\hbar/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \exp\left(-\frac{1}{\hbar} \mathcal{A}_l^N\right) \quad (8.95)$$

agrees precisely with what would have been obtained by naively time-slicing the continuum path integral

$$(r_b \tau_b | r_a \tau_a)_l = \int_0^\infty \mathcal{D}r(\tau) e^{-\frac{1}{\hbar} \mathcal{A}_l[r]}, \quad (8.96)$$

with the radial action

$$\mathcal{A}_l[r] = \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{r}^2 + \frac{\hbar^2}{2M} \frac{l(l+1)}{r^2} + V(r) \right]. \quad (8.97)$$

In particular, this would contain the correct centrifugal barrier

$$V_{\text{cf}} = \frac{\hbar^2}{2M} \frac{l(l+1)}{r^2}. \quad (8.98)$$

However, as we know from the discussion in Section 8.2, Eq. (8.95) is incorrect and must be replaced by (8.92), due to the non uniformity of the continuum limit $\epsilon \rightarrow 0$ in the integrand of (8.92).

8.5.2 L Dimensions

The generalization to D dimensions is straightforward. The main place where the dimension enters is the expansion of

$$e^{h \cos \Delta\vartheta_n} = e^{-\frac{M}{\hbar\epsilon} r_n r_{n-1} \cos \Delta\vartheta_n}, \quad (8.99)$$

in which $\Delta\vartheta_n$ is the relative angle between D -dimensional vectors \mathbf{x}_n and \mathbf{x}_{n-1} . The expansion reads [compare with (8.5) and (8.83)]

$$e^{h \cos \Delta\vartheta_n} = \sum_{l=0}^{\infty} a_l(h) \frac{l + D/2 - 1}{D/2 - 1} \frac{1}{S_D} C_l^{(D/2-1)}(\cos \Delta\vartheta_n), \quad (8.100)$$

where S_D is the surface of a unit sphere in D dimensions (1.558), and

$$\begin{aligned} a_l(h) &\equiv (2\pi)^{D/2} h^{1-D/2} I_{l+D/2-1}(h) \\ &\equiv e^h \tilde{a}_l(h) = e^h \left(\frac{2\pi}{h}\right)^{(D-1)/2} \tilde{I}_{l+D/2-1}(h). \end{aligned} \quad (8.101)$$

The functions $C_l^{(\alpha)}(\cos \vartheta)$ are the ultra-spherical Gegenbauer polynomials, defined by the expansion

$$\frac{1}{(1 - 2t\alpha + \alpha^2)^\lambda} = \sum_{n=0}^{\infty} C_n^{(\lambda)} \alpha^n. \quad (8.102)$$

The expansion (8.100) follows from the completeness of the polynomials $C_l^{(\nu)}(\cos \vartheta)$ at fixed ν , using the integration formulas⁴

$$\int_0^\pi d\vartheta \sin^\nu \vartheta e^{h \cos \vartheta} C_l^{(\nu)}(\cos \vartheta) = \pi \frac{2^{1-\nu} \Gamma(2\nu + l)}{l! \Gamma(\nu)} h^{-\nu} I_{\nu+l}(h), \quad (8.103)$$

$$\int_0^\pi d\vartheta \sin^\nu \vartheta C_l^{(\nu)}(\cos \vartheta) C_{l'}^{(\nu)}(\cos \vartheta) = \pi \frac{2^{1-2\nu} \Gamma(2\nu + l)}{l!(l + \nu) \Gamma(\nu)^2} \delta_{ll'}. \quad (8.104)$$

The Gegenbauer polynomials are related to Jacobi polynomials, which are defined in terms of hypergeometric functions (1.453) by⁵

$$P_l^{(\alpha, \beta)}(z) \equiv \frac{1}{l!} \frac{\Gamma(l + 1 + \beta)}{\Gamma(1 + \beta)} F(-l, l + 1 + \alpha + \beta; 1 + \beta; (1 - z)/2). \quad (8.105)$$

The relation is

$$C_l^{(\nu)}(z) = \frac{\Gamma(2\nu + l) \Gamma(\nu + 1/2)}{\Gamma(2\nu) \Gamma(\nu + l + 1/2)} P_l^{(\nu-1/2, \nu-1/2)}(z). \quad (8.106)$$

This follows from the relation⁶

$$C_l^{(\nu)}(z) = \frac{1}{l!} \frac{\Gamma(l + 2\nu)}{\Gamma(2\nu)} F(-l, l + 2\nu; 1/2 + \nu; (1 - z)/2). \quad (8.107)$$

For $D = 2$ and 3 , one has⁷

$$\lim_{\nu \rightarrow 0} \frac{1}{\nu} C_l^{(\nu)}(\cos \vartheta) = \frac{1}{2l} \cos l\vartheta, \quad (8.108)$$

$$C_l^{(1/2)}(\cos \vartheta) = P_l^{(0,0)}(\cos \vartheta) = P_l(\cos \vartheta), \quad (8.109)$$

and the expansion (8.100) reduces to (8.5) and (8.7), respectively.

For $D = 4$

$$C_l^{(1)}(\cos \vartheta) = \frac{\sin(l + 1)\beta}{\sin \beta}. \quad (8.110)$$

According to an addition theorem, the Gegenbauer polynomials can be decomposed into a sum of pairs of D -dimensional ultra-spherical harmonics $Y_{\mathbf{lm}}(\hat{\mathbf{x}})$.⁸ The label \mathbf{m} stands collectively for the set of *magnetic* quantum numbers

$m_1, m_2, m_3, \dots, m_{D-1}$ with $1 \leq m_1 \leq m_2 \leq \dots \leq |m_{D-2}|$. The direction $\hat{\mathbf{x}}$ of a vector \mathbf{x} is specified by $D - 1$ polar angles

$$\begin{aligned}\hat{x}^1 &= \sin \varphi_{D-1} \cdots \sin \varphi_1, \\ \hat{x}^2 &= \sin \varphi_{D-1} \cdots \cos \varphi_1, \\ &\vdots \\ \hat{x}^D &= \cos \varphi_{D-1},\end{aligned}\tag{8.111}$$

with the ranges

$$0 \leq \varphi_1 < 2\pi,\tag{8.112}$$

$$0 \leq \varphi_i < \pi, \quad i \neq 1.\tag{8.113}$$

The ultra-spherical harmonics $Y_{l\mathbf{m}}(\hat{\mathbf{x}})$ form an orthonormal and complete set of functions on the D -dimensional unit sphere. For a fixed quantum number l of total angular momentum, the label \mathbf{m} can take

$$d_l = \frac{(2l + D - 2)(l + D - 3)!}{l!(D - 2)!}\tag{8.114}$$

different values. The functions are orthonormal,

$$\int d\hat{\mathbf{x}} Y_{l\mathbf{m}}^*(\hat{\mathbf{x}}) Y_{l'\mathbf{m}'}(\hat{\mathbf{x}}) = \delta_{ll'} \delta_{\mathbf{m}\mathbf{m}'},\tag{8.115}$$

with $\int d\hat{\mathbf{x}}$ denoting the integral over the surface of the unit sphere:

$$\int d\hat{\mathbf{x}} = \int d\varphi_{D-1} \sin^{D-2} \varphi_{D-1} \int d\varphi_{D-2} \sin^{D-3} \varphi_{D-2} \cdots \int d\varphi_2 \sin \varphi_2 \int d\varphi_1.\tag{8.116}$$

By evaluating this integral over a unit integrand⁹ we find $S_D = 2\pi^{D/2}/\Gamma(D/2)$ as anticipated in Eq. (1.558). Since $Y_{00}(\hat{\mathbf{x}})$ is independent of $\hat{\mathbf{x}}$, the integral (8.115) implies that $Y_{00}(\hat{\mathbf{x}}) = 1/\sqrt{S_D}$.

Note that the integral over the unit sphere in D -dimensions can be decomposed recursively into an angular integration with respect to any selected direction, say $\hat{\mathbf{u}}$, in the space followed by an integral over a sphere of radius $\sin \varphi_{D-1}$ in the remaining $D - 1$ -dimensional space to $\hat{\mathbf{u}}$. If $\hat{\mathbf{x}}^\perp$ denotes the unit vector covering the directions in this remaining space, one decomposes $\hat{\mathbf{x}} = (\cos \varphi_D \hat{\mathbf{u}} + \sin \varphi_D \hat{\mathbf{x}}^\perp)$, and can factorize the integral measure as

$$\int d^{D-1} \hat{\mathbf{x}} = \int d\varphi_{D-1} \sin^{D-2} \varphi_{D-1} \int d^{D-2} \hat{\mathbf{x}}_\perp.\tag{8.117}$$

For clarity, the dimensionalities of initial and remaining surfaces are marked as superscripts on the measure symbols $d^{D-1} \hat{\mathbf{x}}$ and $d^{D-2} \hat{\mathbf{x}}^\perp$.

⁹With the help of the integral formula $\int_0^\pi d\varphi \sin^k \varphi = \sqrt{\pi} \Gamma((k+1)/2) / \Gamma((k+2)/2)$ we find $S_D = \prod_{k=0}^{D-1} \int_0^\pi d\varphi_k \sin^k \varphi_k = 2\pi^{D/2} \prod_{k=1}^{D-2} \Gamma((k+1)/2) / \prod_{k=1}^{D-2} \Gamma((k+2)/2) = 2\pi^{D/2} / \Gamma(D/2)$.

For the surface of the sphere, this corresponds to the recursion relation

$$S_D = \frac{\sqrt{\pi}\Gamma((D-1)/2)}{\Gamma(D/2)} \times S_{D-1}, \quad (8.118)$$

which is solved by $S_D = 2\pi^{D/2}/\Gamma(D)$.

In four dimensions, the unit vectors $\hat{\mathbf{x}}$ have a parametrization in terms of polar angles

$$\hat{\mathbf{x}} = (\cos \theta, \sin \theta \cos \psi, \sin \theta \sin \psi \cos \varphi, \sin \theta \sin \psi \sin \varphi), \quad (8.119)$$

with the integration measure

$$d\hat{\mathbf{x}} = d\theta \sin^2 \theta d\psi \sin \psi d\varphi. \quad (8.120)$$

It is, however, more convenient to go over to another parametrization in terms of the three Euler angles which are normally used in the kinematic description of the spinning top. In terms of these, the unit vectors have the components

$$\begin{aligned} \hat{x}^1 &= \cos(\theta/2) \cos[(\varphi + \gamma)/2], \\ \hat{x}^2 &= -\cos(\theta/2) \sin[(\varphi + \gamma)/2], \\ \hat{x}^3 &= \sin(\theta/2) \cos[(\varphi - \gamma)/2], \\ \hat{x}^4 &= \sin(\theta/2) \sin[(\varphi - \gamma)/2], \end{aligned} \quad (8.121)$$

with the angles covering the intervals

$$\theta \in [0, \pi), \quad \varphi \in [0, 2\pi), \quad \gamma \in [-2\pi, 2\pi). \quad (8.122)$$

We have renamed the usual Euler angles α, β, γ introduced in Section 1.15 calling them φ, θ, γ , since the formulas to be derived for them will be used in a later application in Chapter 13 [see Eq. (13.102)]. There the first two Euler angles coincide with the polar angles φ, θ of a position vector in a three-dimensional space. It is important to note that for a description of the entire surface of the sphere, the range of the angle γ must be twice as large as for the classical spinning top. The associated group space belongs to the covering group, of the rotation group which is equivalent to the group of unimodular matrices in two dimensions called SU(2). It is defined by the matrices

$$g(\varphi, \theta, \gamma) = \exp(i\varphi\sigma_3/2) \exp(i\theta\sigma_2/2) \exp(i\gamma\sigma_3/2), \quad (8.123)$$

where σ_i are the Pauli spin matrices (1.448). In this parametrization, the integration measure reads

$$d\hat{\mathbf{x}} = \frac{1}{8} d\theta \sin \theta d\varphi d\gamma. \quad (8.124)$$

When integrated over the surface, the two measures give the same result $S_4 = 2\pi^2$. The Euler parametrization has the advantage of allowing the spherical harmonics in

four dimensions to be expressed in terms of the well-known representation functions of the rotation group introduced in (1.445), (1.446):

$$Y_{l,m_1,m_2}(\hat{\mathbf{x}}) = \sqrt{\frac{l+1}{2\pi^2}} \mathcal{D}_{m_1 m_2}^{l/2}(\varphi, \theta, \gamma) = \sqrt{\frac{l+1}{2\pi^2}} d_{m_1 m_2}^{l/2}(\theta) e^{i(m_1 \varphi + m_2 \gamma)}. \quad (8.125)$$

For even and odd l , the numbers m_1, m_2 are both integer or half-integer, respectively.

In arbitrary dimensions $D > 2$, the ultra-spherical Gegenbauer polynomials satisfy the following addition theorem

$$\frac{2l+D-2}{D-2} \frac{1}{S_D} C_l^{(D/2-1)}(\cos \Delta\vartheta_n) = \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\hat{\mathbf{x}}_n) Y_{l\mathbf{m}}^*(\hat{\mathbf{x}}_{n-1}). \quad (8.126)$$

For $D = 3$, this reduces properly to the well-known addition theorem for the spherical harmonics

$$\frac{1}{4\pi} (2l+1) P_l(\cos \Delta\vartheta_n) = \sum_{m=-l}^l Y_{lm}(\hat{\mathbf{x}}_n) Y_{lm}^*(\hat{\mathbf{x}}_{n-1}). \quad (8.127)$$

For $D = 4$, it becomes¹⁰

$$\frac{l+1}{2\pi^2} C_l^{(1)}(\cos \Delta\vartheta_n) = \frac{l+1}{2\pi^2} \sum_{m_1, m_2 = -l/2}^{l/2} \mathcal{D}_{m_1 m_2}^{l/2}(\varphi_n, \theta_n, \gamma_n) \mathcal{D}_{m_1 m_2}^{l/2*}(\varphi_{n-1}, \theta_{n-1}, \gamma_{n-1}), \quad (8.128)$$

where the angle $\Delta\vartheta_n$ is related to the Euler angles of the vectors $\mathbf{x}_n, \mathbf{x}_{n-1}$ by

$$\begin{aligned} \cos \Delta\vartheta_n &= \cos(\theta_n/2) \cos(\theta_{n-1}/2) \cos[(\varphi_n - \varphi_{n-1} + \gamma_n - \gamma_{n-1})/2] \\ &\quad + \sin(\theta_n/2) \sin(\theta_{n-1}/2) \cos[(\varphi_n - \varphi_{n-1} - \gamma_n + \gamma_{n-1})/2]. \end{aligned} \quad (8.129)$$

Using (8.126), we can rewrite the expansion (8.100) in the form

$$e^{h(\cos \Delta\vartheta_{n-1})} = \sum_{l=0}^{\infty} \tilde{a}_l(h) \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\hat{\mathbf{x}}_n) Y_{l\mathbf{m}}^*(\hat{\mathbf{x}}_{n-1}). \quad (8.130)$$

This is now valid for any dimension D , including the case $D = 2$ where the left-hand side of (8.126) involves the limiting procedure (8.108). We shall see in Chapter 9 in connection with Eq. (9.61) that it also makes sense to apply this expansion to the case $D = 1$ where the “partial-wave expansion” degenerates into a separation of even and odd wave functions. In four dimensions, we shall mostly prefer the expansion

$$e^{h(\cos \Delta\vartheta_{n-1})} = \sum_{l=0}^{\infty} \tilde{a}_l(h) \frac{l+1}{2\pi^2} \sum_{m_1, m_2 = -l/2}^{l/2} \mathcal{D}_{m_1 m_2}^{l/2}(\varphi_n, \theta_n, \gamma_n) \mathcal{D}_{m_1 m_2}^{l/2*}(\varphi_{n-1}, \theta_{n-1}, \gamma_{n-1}), \quad (8.131)$$

¹⁰Note that $C_l^{(1)}(\cos \Delta\vartheta_n)$ coincides with the trace over the representation functions (1.446) of the rotation group, i.e., it is equal to $\sum_{m=-l/2}^{l/2} d_{m,m}^{l/2}(\Delta\vartheta_n)$.

where the sum over m_1, m_2 runs for even and odd l over integer and half-integer numbers, respectively.

The reduction of the time evolution amplitude in D dimensions to a radial path integral proceeds from here on in the same way as in two and three dimensions. The generalization of (8.89) reads

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &\approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}^D} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n r_n^{D-1} d\hat{\mathbf{x}}_n}{\sqrt{2\pi\hbar\epsilon/M}^D} \right] \\ &\times \prod_{n=1}^{N+1} \left[\left(\frac{2\pi\hbar\epsilon}{Mr_n r_{n-1}} \right)^{(D-1)/2} \sum_{l_n=0}^\infty \tilde{I}_{D/2-1+l_n} \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) \right. \\ &\left. \times \sum_{\mathbf{m}_n} Y_{l_n \mathbf{m}_n}(\hat{\mathbf{x}}_n) Y_{l_n \mathbf{m}_n}^*(\hat{\mathbf{x}}_{n-1}) \right] \exp \left\{ -\frac{\epsilon}{\hbar} \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (r_n - r_{n-1})^2 + V(r_n) \right] \right\}. \end{aligned} \quad (8.132)$$

By performing the angular integrals and using the orthogonality relations (8.115), the product of sums over l_n, \mathbf{m}_n reduces to a single sum over l, \mathbf{m} , just as in the three-dimensional amplitude (8.91). The result is the spherical decomposition

$$(\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) = \frac{1}{(r_b r_a)^{(D-1)/2}} \sum_{l=0}^\infty (r_b \tau_b | r_a \tau_a)_l \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\hat{\mathbf{x}}_b) Y_{l\mathbf{m}}^*(\hat{\mathbf{x}}_a), \quad (8.133)$$

where $(r_b \tau_b | r_a \tau_a)_l$ is the purely radial amplitude

$$(r_b \tau_b | r_a \tau_a)_l \approx \frac{1}{\sqrt{2\pi\hbar\epsilon/M}} \prod_{n=1}^N \left[\int_0^\infty \frac{dr_n}{\sqrt{2\pi\hbar\epsilon/M}} \right] \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_l^N[r] \right\}, \quad (8.134)$$

with the time-sliced action

$$\mathcal{A}_l^N[r] = \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (r_n - r_{n-1})^2 - \frac{\hbar}{\epsilon} \log \tilde{I}_{l+D/2-1} \left(\frac{M}{\hbar\epsilon} r_n r_{n-1} \right) + V(r_n) \right]. \quad (8.135)$$

As before, the product $\prod_{n=1}^{N+1} 1/(r_n r_{n-1})^{(D-1)/2}$ has removed the product $\prod_{n=1}^N r_n^{D-1}$ in the measure as well as the factor $(r_b r_a)^{(D-1)/2}$ in front of it, leaving only the standard one-dimensional measure of integration.

In the continuum limit $\epsilon \rightarrow 0$, the asymptotic expression (8.24) for the Bessel function brings the action to the form

$$\mathcal{A}_l^N[r, \bar{r}] \approx \epsilon \sum_{n=1}^{N+1} \left[\frac{M}{2\epsilon^2} (r_n - r_{n-1})^2 + \frac{\hbar^2}{2M} \frac{(l + D/2 - 1)^2 - 1/4}{r_n r_{n-1}} + V(r_n) \right]. \quad (8.136)$$

This looks again like the time-sliced version of the radial path integral in D dimensions

$$(r_b \tau_b | r_a \tau_a)_l = \int \mathcal{D}r(\tau) \exp \left\{ -\frac{1}{\hbar} \mathcal{A}_l[r] \right\}, \quad (8.137)$$

with the continuum action

$$\mathcal{A}_l[r] = \int_{\tau_a}^{\tau_b} d\tau \left[\frac{M}{2} \dot{r}^2 + \frac{\hbar^2}{2M} \frac{(l + D/2 - 1)^2 - 1/4}{r^2} + V(r) \right]. \quad (8.138)$$

As in Eq. (8.50), we have written the centrifugal barrier as

$$\frac{\hbar^2}{2Mr^2} [(l + D/2 - 1)^2 - 1/4], \quad (8.139)$$

to emphasize the subtleties of the time-sliced radial path integral, with the understanding that the time-sliced barrier reads [as in (8.51)]

$$\frac{\epsilon \hbar^2}{2Mr_n r_{n-1}} [(l + D/2 - 1)^2 - 1/4] \equiv -\hbar \log \tilde{I}_{l+D/2-1} \left(\frac{M}{\hbar \epsilon} r_n r_{n-1} \right). \quad (8.140)$$

8.6 Radial Path Integral for Harmonic Oscillator and Free Particle in L Dimensions

For the harmonic oscillator and the free particle, there is no need to perform the radial path integral (8.134) with the action (8.135). As in (8.38), we simply take the known amplitude in D dimensions, (2.177), continue it to imaginary times $t = -i\tau$, and expand it with the help of (8.130):

$$\begin{aligned} (\mathbf{x}_b \tau_b | \mathbf{x}_a \tau_a) &= \frac{1}{\sqrt{2\pi\hbar/M}^D} \sqrt{\frac{\omega}{\sinh[\omega(\tau_b - \tau_a)]}}^D \\ &\times \exp \left\{ -\frac{1}{\hbar} \frac{M\omega}{\sinh[\omega(\tau_b - \tau_a)]} (r_b^2 + r_a^2) \cosh[\omega(\tau_b - \tau_a)] \right\} \\ &\times \sum_{l=0}^{\infty} a_l \left(\frac{M\omega r_b r_a}{\hbar \sinh[\omega(\tau_b - \tau_a)]} \right) \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\hat{\mathbf{x}}_b) Y_{l\mathbf{m}}^*(\hat{\mathbf{x}}_a). \end{aligned} \quad (8.141)$$

Comparing this with Eq. (8.133) and remembering (8.101), we identify the radial amplitude as

$$\begin{aligned} (r_b \tau_b | r_a \tau_a)_l &= \frac{M}{\hbar} \frac{\omega \sqrt{r_b r_a}^{D-1}}{\sinh[\omega(\tau_b - \tau_a)]} \\ &\times e^{-(M\omega/2\hbar) \coth[\omega(\tau_b - \tau_a)](r_b^2 + r_a^2)} I_{l+D/2-1} \left(\frac{M\omega r_b r_a}{\hbar \sinh[\omega(\tau_b - \tau_a)]} \right), \end{aligned} \quad (8.142)$$

generalizing (8.39). The limit $\omega \rightarrow 0$ yields the amplitude for a free particle

$$(r_b \tau_b | r_a \tau_a)_l = \frac{M}{\hbar} \frac{\sqrt{r_b r_a}^{D-1}}{(\tau_b - \tau_a)} e^{-M(r_b^2 + r_a^2)/2\hbar(\tau_b - \tau_a)} I_{l+D/2-1} \left(\frac{Mr_b r_a}{\hbar(\tau_b - \tau_a)} \right). \quad (8.143)$$

Comparing this with (8.40) on the one hand and Eqs. (8.140), (8.138) with (8.49), (8.51) on the other hand, we conclude: An analytical continuation in D yields the

path integral for a linear oscillator in the presence of an arbitrary $1/r^2$ -potential as follows:

$$\begin{aligned} (r_b\tau_b|r_a\tau_a)_l &= \int_0^\infty \mathcal{D}r(\tau) \exp \left[-\frac{1}{\hbar} \int_{\tau_a}^{\tau_b} d\tau \left(\frac{M}{2} \dot{r}^2 + \frac{\hbar^2}{2M} \frac{\mu^2 - 1/4}{r^2} + \frac{M}{2} \omega^2 r^2 \right) \right] \\ &= \frac{M}{\hbar} \frac{\omega \sqrt{r_b r_a}^{D-1}}{\sinh[\omega(\tau_b - \tau_a)]} e^{-(M\omega/2\hbar) \coth[\omega(\tau_b - \tau_a)](r_b^2 + r_a^2)} I_\mu \left(\frac{M\omega r_b r_a}{\hbar \sinh[\omega(\tau_b - \tau_a)]} \right). \end{aligned} \quad (8.144)$$

Here μ is some strength parameter which initially takes the values $\mu = l + D/2 - 1$ with integer l and D . By analytic continuation, the range of validity is extended to all real $\mu > 0$. The justification for the continuation procedure follows from the fact that the integral formula (8.14) holds for arbitrary $m = \mu \geq 0$. The amplitude (8.144) satisfies therefore the fundamental composition law (8.20) for all real $m = \mu \geq 0$. The harmonic oscillator with an arbitrary extra centrifugal barrier potential

$$V_{\text{extra}}(r) = \hbar^2 \frac{l_{\text{extra}}^2}{2Mr^2} \quad (8.145)$$

has therefore the radial amplitude (8.144) with

$$\mu = \sqrt{(l + D/2 - 1)^2 + l_{\text{extra}}^2}. \quad (8.146)$$

For a finite number $N + 1$ of time slices, the radial amplitude is known from the angular momentum expansion of the finite- N oscillator amplitude (2.199) in its obvious extension to D dimensions. It can also be calculated directly as in Appendix 2B by a successive integration of (8.132), using formula (8.14). The iteration formulas are the Euclidean analogs of those derived in Appendix 2B, with the prefactor of the amplitude being $2\pi \mathcal{N}_1^2 \mathcal{N}_{N+1}^2 \sqrt{r_b r_a}$, with the exponent $-a_{N+1}(r_b^2 + r_a^2)/\hbar$, and with the argument of the Bessel function $2b_{N+1}r_b r_a/\hbar$. In this way we obtain precisely the expression (8.144), except that $\sinh[\omega(\tau_b - \tau_a)]$ is replaced by $\sinh[\tilde{\omega}(N+1)\epsilon]/\sinh \tilde{\omega}\epsilon$ and $\cosh[\omega(\tau_b - \tau_a)]$ by $\cosh[\tilde{\omega}(N+1)\epsilon]$.

8.7 Particle near the Surface of a Sphere in D Dimensions

With the insight gained in the previous sections, it is straightforward to calculate exactly a certain class of auxiliary path integrals. They involve only angular variables and will be called path integrals of a point particle moving *near* the surface of a sphere in D dimensions. The resulting amplitudes lead eventually to the physically more relevant amplitudes describing the behavior of a particle *on* the surface of a sphere.

On the surface of a sphere of radius r , the position of the particle as a function of time is specified by a unit vector $\mathbf{u}(t)$. The Euclidean action is

$$\mathcal{A} = \frac{M}{2} r^2 \int_{\tau_a}^{\tau_b} d\tau \dot{\mathbf{u}}^2(\tau). \quad (8.147)$$

The precise way of time-slicing this action is not known from previous discussions. It cannot be *deduced* from the time-sliced action in Cartesian coordinates, nor from its angular momentum decomposition. A new geometric feature makes the previous procedures inapplicable: The surface of a sphere is a Riemannian space with nonzero intrinsic curvature. Sections 1.13 to 1.15 have shown that the motion in a curved space does not follow the canonical quantization rules of operator quantum mechanics. The same problem is encountered here in another form: Right in the beginning, we are not allowed to time-slice the action (8.147) in a straightforward way. The correct slicing is found in two steps. First we use the experience gained with the angular momentum decomposition of time-sliced amplitudes in a Euclidean space to introduce and solve the earlier mentioned auxiliary time-sliced path integral *near* the surface of the sphere. In a second step we shall implement certain corrections to properly describe the action *on* the sphere. At the end, we have to construct the correct measure of path integration which will not be what one naively expects. To set up the auxiliary path integral *near* the surface of a sphere we observe that the kinetic term of a time slice in D dimensions

$$\frac{M}{2\epsilon} \sum_{n=1}^{N+1} (r_n^2 + r_{n-1}^2 - 2r_n r_{n-1} \cos \Delta\vartheta_n) \quad (8.148)$$

decomposes into radial and angular parts as

$$-\frac{M}{2\epsilon} \sum_{n=1}^{N+1} (r_n^2 + r_{n-1}^2 - 2r_n r_{n-1}) + \frac{M}{2\epsilon} \sum_{n=1}^{N+1} 2r_n r_{n-1} (1 - \cos \Delta\vartheta_n). \quad (8.149)$$

The angular factor can be written as

$$-\frac{M}{2\epsilon} \sum_{n=1}^{N+1} r_n r_{n-1} (\hat{\mathbf{x}}_n - \hat{\mathbf{x}}_{n-1})^2, \quad (8.150)$$

where $\hat{\mathbf{x}}_n, \hat{\mathbf{x}}_{n-1}$ are the unit vectors pointing in the directions of $\mathbf{x}_n, \mathbf{x}_{n-1}$ [recall (8.111)]. Restricting all radial variables r_n to the surface of a sphere of a fixed radius r and identifying $\hat{\mathbf{x}}$ with \mathbf{u} leads us directly to the time-sliced path integral *near* the surface of the sphere in D dimensions:

$$(\mathbf{u}_b \tau_b | \mathbf{u}_a \tau_a) \approx \frac{1}{\sqrt{2\pi\hbar\epsilon/Mr^2}^{D-1}} \prod_{n=1}^N \left[\int \frac{d\mathbf{u}_n}{\sqrt{2\pi\hbar\epsilon/Mr^2}^{D-1}} \right] \exp\left(-\frac{1}{\hbar} \mathcal{A}^N\right), \quad (8.151)$$

with the sliced action

$$\mathcal{A}^N = \frac{M}{2\epsilon} r^2 \sum_{n=1}^{N+1} (\mathbf{u}_n - \mathbf{u}_{n-1})^2. \quad (8.152)$$

The measure $d\mathbf{u}_n$ denotes infinitesimal surface elements on the sphere in D dimensions [recall (8.116)]. Note that although the endpoints \mathbf{u}_n lie all on the sphere, the paths remain only *near* the sphere since the path sections between the points leave

the surface and traverse the embedding space along a straight line. This will be studied further in Section 8.8.

As mentioned above, this amplitude can be solved exactly. In fact, for each time interval ϵ , the exponential

$$\exp \left[-\frac{Mr^2}{2\hbar\epsilon} (\mathbf{u}_n - \mathbf{u}_{n-1})^2 \right] = \exp \left[-\frac{Mr^2}{\hbar\epsilon} (1 - \cos \Delta\vartheta_n) \right] \tag{8.153}$$

can be expanded into spherical harmonics according to formulas (8.100)–(8.101),

$$\begin{aligned} \exp \left[-\frac{Mr^2}{2\hbar\epsilon} (\mathbf{u}_n - \mathbf{u}_{n-1})^2 \right] &= \sum_{l=0}^{\infty} \tilde{a}_l(h) \frac{l + D/2 - 1}{D/2 - 1} \frac{1}{S_D} C_l^{(D/2-1)}(\cos \Delta\vartheta_n) \\ &= \sum_{l=0}^{\infty} \tilde{a}_l(h) \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\mathbf{u}_n) Y_{l\mathbf{m}}^*(\mathbf{u}_{n-1}), \end{aligned} \tag{8.154}$$

where

$$\tilde{a}_l(h) = \left(\frac{2\pi}{h} \right)^{(D-1)/2} \tilde{I}_{l+D/2-1}(h), \quad h = \frac{Mr^2}{\hbar\epsilon}. \tag{8.155}$$

For each adjacent pair $(n + 1, n)$, $(n, n - 1)$ of such factors in the sliced path integral, the integration over the intermediate \mathbf{u}_n variable can be done using the orthogonality relation (8.115). In this way, (8.151) produces the time-sliced amplitude

$$(\mathbf{u}_b\tau_b | \mathbf{u}_a\tau_a) = \left(\frac{h}{2\pi} \right)^{(N+1)(D-1)/2} \sum_{l=0}^{\infty} \tilde{a}_l(h)^{N+1} \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\mathbf{u}_b) Y_{l\mathbf{m}}^*(\mathbf{u}_a). \tag{8.156}$$

We now go to the continuum limit $N \rightarrow \infty$, $\epsilon = (\tau_b - \tau_a)/(N + 1) \rightarrow 0$, where [recall (8.11)]

$$\begin{aligned} \left(\frac{h}{2\pi} \right)^{(N+1)(D-1)/2} \tilde{a}_l(h)^{N+1} &= \left[\tilde{I}_{l+D/2-1} \left(\frac{Mr^2}{\hbar\epsilon} \right) \right]^{N+1} \\ &\xrightarrow{\epsilon \rightarrow 0} \exp \left\{ -(\tau_b - \tau_a) \hbar \frac{(l + D/2 - 1)^2 - 1/4}{2Mr^2} \right\}. \end{aligned} \tag{8.157}$$

Thus, the final time evolution amplitude for the motion *near* the surface of the sphere is

$$(\mathbf{u}_b\tau_b | \mathbf{u}_a\tau_a) = \sum_{l=0}^{\infty} \exp \left[-\frac{\hbar L_2}{2Mr^2} (\tau_b - \tau_a) \right] \sum_{\mathbf{m}} Y_{l\mathbf{m}}(\mathbf{u}_b) Y_{l\mathbf{m}}^*(\mathbf{u}_a), \tag{8.158}$$

with

$$L_2 \equiv (l + D/2 - 1)^2 - 1/4. \tag{8.159}$$

For $D = 3$, this amounts to an expansion in terms of associated Legendre polynomials

$$\begin{aligned} (\mathbf{u}_b\tau_b | \mathbf{u}_a\tau_a) &= \sum_{l=0}^{\infty} \frac{2l + 1}{4\pi} \exp \left\{ -\frac{\hbar L_2}{2Mr^2} (\tau_b - \tau_a) \right\} \\ &\quad \times \sum_{m=-l}^l \frac{(l - m)!}{(l + m)!} P_l^m(\cos \theta_b) P_l^m(\cos \theta_a) e^{im(\varphi_b - \varphi_a)}. \end{aligned} \tag{8.160}$$

If the initial point lies at the north pole of the sphere, this simplifies to

$$(\mathbf{u}_b\tau_b|\hat{\mathbf{z}}_a\tau_a) = \sum_{l=0}^{\infty} \frac{2l+1}{4\pi} \exp\left[-\frac{\hbar L_2}{2Mr^2}(\tau_b - \tau_a)\right] P_l(\cos\theta_b)P_l(1), \quad (8.161)$$

where $P_l(1) = 1$. By rotational invariance the same result holds for arbitrary directions of \mathbf{u}_a , if θ_b is replaced by the difference angle ϑ between \mathbf{u}_b and \mathbf{u}_a .

In four dimensions, the most convenient expansion uses again the representation functions of the rotation group, so that (8.158) reads

$$\begin{aligned} (\mathbf{u}_b\tau_b|\mathbf{u}_a\tau_a) &= \sum_{l=0}^{\infty} \exp\left[-\frac{\hbar L_2}{2Mr^2}(\tau_b - \tau_a)\right] \\ &\times \frac{l+1}{2\pi^2} \sum_{m_1, m_2=-l/2}^{l/2} \mathcal{D}_{m_1 m_2}^{l/2}(\varphi_b, \theta_b, \gamma_b) \mathcal{D}_{m_1 m_2}^{l/2*}(\varphi_a, \theta_a, \gamma_a). \end{aligned} \quad (8.162)$$

These results will be needed in Sections 8.9 and 10.4 to calculate the amplitudes *on* the surface of a sphere. First, however, we extract some more information from the amplitudes *near* the surface of the sphere.

8.8 Angular Barriers *near* the Surface of a Sphere

In Section 8.5 we have projected the path integral of a free particle in three dimensions into a state of fixed angular momentum l finding a radial path integral containing a singular potential, the centrifugal barrier. This could not be treated via the standard time-slicing formalism. The projection of the path integral, however, supplied us with a valid time-sliced action and yielded the correct amplitude. A similar situation occurs if we project the path integral near the surface of a sphere into a fixed azimuthal quantum number m . The physics very near the poles of a sphere is almost the same as that on the tangential surfaces at the poles. Thus, at a fixed two-dimensional angular momentum, the tangential surfaces contain centrifugal barriers. We expect analogous centrifugal barriers at a fixed azimuthal quantum number m near the poles of a sphere at a fixed azimuthal quantum number m . These will be called *angular barriers*.

8.8.1 Angular Barriers in Three Dimensions

Consider first the case $D = 3$ where the azimuthal decomposition is

$$(\mathbf{u}_b\tau_b|\mathbf{u}_a\tau_a) = \sum_m (\sin\theta_b\tau_b|\sin\theta_a\tau_a)_m \frac{1}{2\pi} e^{im(\varphi_b - \varphi_a)}. \quad (8.163)$$

It is convenient to introduce also the differently normalized amplitude

$$(\theta_b\tau_b|\theta_a\tau_a)_m \equiv \sqrt{\sin\theta_b \sin\theta_a} (\sin\theta_b\tau_b|\sin\theta_a\tau_a)_m, \quad (8.164)$$

in terms of which the expansion reads

$$(\mathbf{u}_b\tau_b|\mathbf{u}_a\tau_a) = \sum_m \frac{1}{\sqrt{\sin\theta_b\sin\theta_a}} (\theta_b\tau_b|\theta_a\tau_a)_m \frac{1}{2\pi} e^{im(\varphi_b-\varphi_a)}. \quad (8.165)$$

While the amplitude $(\sin\theta_b\tau_b|\sin\theta_a\tau_a)_m$ has the equal-time limit

$$(\sin\theta_b\tau|\sin\theta_a\tau)_m = \frac{1}{\sin\theta_a} \delta(\theta_b - \theta_a) \quad (8.166)$$

corresponding to the invariant measure of the θ -integration on the surface of the sphere $\int d\theta \sin\theta$, the new amplitude $(\theta_b\tau_b|\theta_a\tau)_m$ has the limit

$$(\theta_b\tau|\theta_a\tau)_m = \delta(\theta_b - \theta_a) \quad (8.167)$$

with a simple δ -function, just as for a particle moving on the coordinate interval $\theta \in (0, 2\pi)$ with an integration measure $\int d\theta$. The renormalization is analogous to that of the radial amplitudes in (8.9).

The projected amplitude can immediately be read off from Eq. (8.158):

$$\begin{aligned} (\theta_b\tau_b|\theta_a\tau_a)_m &= \sqrt{\sin\theta_b\sin\theta_a} \\ &\times \sum_{l=m}^{\infty} \exp\left[-\frac{\hbar l(l+1)}{2Mr^2}(\tau_b - \tau_a)\right] 2\pi Y_{lm}(\theta_b, 0) Y_{lm}^*(\theta_a, 0). \end{aligned} \quad (8.168)$$

In terms of associated Legendre polynomials [recall (8.84)], this reads

$$\begin{aligned} (\theta_b\tau_b|\theta_a\tau_a)_m &= \sqrt{\sin\theta_b\sin\theta_a} \sum_{l=m}^{\infty} \exp\left\{-\frac{\hbar l(l+1)}{2Mr^2}(\tau_b - \tau_a)\right\} \\ &\times \frac{(2l+1)(l-m)!}{2(l+m)!} P_l^m(\cos\theta_b) P_l^m(\cos\theta_a). \end{aligned} \quad (8.169)$$

Let us look at the time-sliced path integral associated with this amplitude. We start from Eq. (8.151) for $D = 3$,

$$(\mathbf{u}_b\tau_b|\mathbf{u}_a\tau_a) \approx \frac{1}{2\pi\hbar\epsilon/Mr^2} \prod_{n=1}^N \left[\int \frac{d\cos\theta_n d\varphi_n}{2\pi\hbar\epsilon/Mr^2} \right] \exp\left(-\frac{1}{\hbar}\mathcal{A}^N\right), \quad (8.170)$$

and use the addition theorem

$$\cos\Delta\vartheta_n = \cos\theta_n \cos\theta_{n-1} + \sin\theta_n \sin\theta_{n-1} \cos(\varphi_n - \varphi_{n-1}) \quad (8.171)$$

to expand the exponent as

$$\begin{aligned} \exp\left[-\frac{Mr^2}{2\hbar\epsilon}(\mathbf{u}_n - \mathbf{u}_{n-1})^2\right] &= \exp\left[-\frac{Mr^2}{\hbar\epsilon}(1 - \cos\Delta\vartheta_n)\right] \\ &= \exp\left[-\frac{Mr^2}{\hbar\epsilon}(1 - \cos\theta_n \cos\theta_{n-1} - \sin\theta_n \sin\theta_{n-1})\right] \\ &\times \frac{1}{\sqrt{2\pi\hbar_n}} \sum_{m=-\infty}^{\infty} \tilde{I}_m(\hbar_n) e^{im(\varphi_n - \varphi_{n-1})}, \end{aligned} \quad (8.172)$$

where h_n is defined as

$$h_n \equiv \frac{Mr^2}{\hbar\epsilon} \sin \theta_n \sin \theta_{n-1}. \quad (8.173)$$

By doing successively the φ_n -integrations, we wind up with the path integral for the projected amplitude

$$(\theta_b \tau_b | \theta_a \tau_a)_m \approx \frac{1}{\sqrt{2\pi\epsilon\hbar/Mr^2}} \prod_{n=1}^N \left[\int_0^\pi \frac{d\theta_n}{\sqrt{2\pi\epsilon\hbar/Mr^2}} \right] \exp\left(-\frac{1}{\hbar} \mathcal{A}_m^N\right), \quad (8.174)$$

where \mathcal{A}_m^N is the sliced action

$$\mathcal{A}_m^N = \sum_{n=1}^{N+1} \left\{ \frac{Mr^2}{\epsilon} [1 - \cos(\theta_n - \theta_{n-1})] - \hbar \log \tilde{I}_m(h_n) \right\}. \quad (8.175)$$

For small ϵ , this can be approximated (setting $\Delta\theta_n \equiv \theta_n - \theta_{n-1}$) by

$$\mathcal{A}_m^N \approx \epsilon \sum_{n=1}^{N+1} \left\{ \frac{Mr^2}{2\epsilon^2} \left[(\Delta\theta_n)^2 - \frac{1}{12} (\Delta\theta_n)^4 + \dots \right] + \frac{\hbar^2}{2Mr^2} \frac{m^2 - 1/4}{\sin \theta_n \sin \theta_{n-1}} \right\}, \quad (8.176)$$

with the continuum limit

$$\mathcal{A}_m = \int_{\tau_a}^{\tau_b} d\tau \left(\frac{Mr^2}{2} \dot{\theta}^2 - \frac{\hbar^2}{8Mr^2} + \frac{\hbar^2}{2Mr^2} \frac{m^2 - 1/4}{\sin^2 \theta} \right). \quad (8.177)$$

This action has a $1/\sin^2 \theta$ -singularity at $\theta = 0$ and $\theta = \pi$, i.e., at the north and south poles of the sphere, whose similarity with the $1/r^2$ -singularity of the centrifugal barrier justifies the name ‘‘angular barriers’’.

By analogy with the problems discussed in Section 8.2, the amplitude (8.174) with the naively time-sliced action (8.176) does not exist for $m = 0$, this being the path collapse problem to be solved in Chapter 12. With the full time-sliced action (8.175), however, the path integral is stable for all m . In this stable expression, the successive integration of the intermediate variables using formula (8.14) gives certainly the correct result (8.169).

To do such a calculation, we start out from the product of integrals (8.174) and expand in each factor $I_m(h_n)$ with the help of the addition theorem

$$\begin{aligned} & \sqrt{\frac{2\zeta}{\pi}} e^{\zeta \cos \theta_n \cos \theta_{n-1}} I_m(\zeta \sin \theta_n \sin \theta_{n-1}) \\ &= \sum_{l=m}^{\infty} I_{l+1/2}(\zeta) (2l+1) \frac{(l-m)!}{(l+m)!} P_l^m(\cos \theta_n) P_l^m(\cos \theta_{n-1}), \end{aligned} \quad (8.178)$$

where $\zeta \equiv Mr^2/\hbar\epsilon$. This theorem follows immediately from a comparison of two expansions

$$\begin{aligned} e^{-\zeta(1-\cos \Delta\theta_n)} &= e^{-\zeta[1-\cos \theta_n \cos \theta_{n-1} - \sin \theta_n \sin \theta_{n-1} \cos(\varphi_n - \varphi_{n-1})]} \\ &\times \frac{1}{\sqrt{2\pi\zeta \sin \theta_n \sin \theta_{n-1}}} \sum_{m=-\infty}^{\infty} \tilde{I}_m(\zeta \sin \theta_n \sin \theta_{n-1}) e^{im(\varphi_n - \varphi_{n-1})}, \end{aligned} \quad (8.179)$$

$$e^{-\zeta(1-\cos \Delta\theta_n)} = e^{-\zeta} \sqrt{\frac{\pi}{2\zeta}} \sum_{l=0}^{\infty} (2l+1) I_{l+1/2}(\zeta) P_l(\cos \Delta\theta_n). \quad (8.180)$$

The former is obtained with the help (8.5), the second is taken from (8.83). After the comparison, the Legendre polynomial is expanded via the addition theorem (8.85), which we rewrite with (8.84) as

$$P_l(\cos \Delta\theta_n) = \sum_{m=-l}^l \frac{(l-m)!}{(l+m)!} P_l^m(\theta_n) P_l^m(\theta_{n-1}) e^{im(\varphi_n - \varphi_{n-1})}. \quad (8.181)$$

We now recall the orthogonality relation (8.50), rewritten as

$$\int_{-1}^1 \frac{d \cos \theta}{\sin^2 \theta} P_l^m(\cos \theta) P_l^m(\cos \theta) = \frac{(l+m)!}{(l-m)!} \frac{2}{2l+1} \delta_{ll}. \quad (8.182)$$

This allows us to do all angular integrations in (8.175). The result

$$\begin{aligned} (\theta_b \tau_b | \theta_a \tau_a)_m &= \sqrt{\sin \theta_b \sin \theta_a} \sum_{l=m}^{\infty} [\tilde{I}_{m+l+1/2}(\zeta)]^{N+1} \\ &\quad \times \frac{(2l+1)}{2} \frac{(l-m)!}{(l+m)!} P_l^m(\cos \theta_b) P_l^m(\cos \theta_a) \end{aligned} \quad (8.183)$$

is the solution of the time-sliced path integral (8.174).

In the continuum limit, $[\tilde{I}_{m+l+1/2}(\zeta)]^{N+1}$ is dominated by the leading asymptotic term of (8.12) so that

$$[\tilde{I}_{m+l+1/2}(\zeta)]^{N+1} \approx \exp \left[-\frac{\hbar}{2Mr^2} L_2(\tau_b - \tau_a) \right], \quad (8.184)$$

leading to the previously found expression (8.169).

We have gone through this calculation in detail for the following purpose. Later applications will require an analytic continuation of the path integral from integer values of m to arbitrary real values $\mu \geq 0$. With the present calculation, such a continuation is immediately possible by rewriting (8.183) with the help of the relation

$$P_l^m(z) = (-)^m P_l^{-m} \frac{(l+m)!}{(l-m)!} \quad (8.185)$$

as

$$\begin{aligned} (\theta_b \tau_b | \theta_a \tau_a)_\mu &= \sqrt{\sin \theta_b \sin \theta_a} \sum_{n=0}^{\infty} [\tilde{I}_{n+\mu+1/2}(\zeta)]^{N+1} \\ &\quad \times \frac{(2n+2\mu+1)}{2} \frac{(n+2\mu)!}{n!} P_{n+\mu}^{-\mu}(\cos \theta_b) P_{n+\mu}^{-\mu}(\cos \theta_a). \end{aligned} \quad (8.186)$$

Here, μ can be an arbitrary real number if the factorials $(n+2\mu)!$ and $n!$ are defined as $\Gamma(n+2\mu+1)$ and $\Gamma(n+1)$. In the continuum limit, (8.186) becomes

$$\begin{aligned} (\theta_b \tau_b | \theta_a \tau_a)_\mu &= \sqrt{\sin \theta_b \sin \theta_a} \sum_{n=0}^{\infty} \exp \left[-\frac{\hbar(n+\mu)(n+\mu+1)}{2Mr^2} (\tau_b - \tau_a) \right] \\ &\quad \times \frac{(2n+2\mu+1)}{2} \frac{(n+2\mu)!}{n!} P_{n+\mu}^{-\mu}(\cos \theta_b) P_{n+\mu}^{-\mu}(\cos \theta_a). \end{aligned} \quad (8.187)$$

We prove this to solve the time-sliced path integral (8.174) for arbitrary real values of $m = \mu$ [4] by using the addition theorem¹¹

$$\begin{aligned} (\sin \alpha \sin \beta)^{-\mu} J_{\mu}(z \sin \alpha \sin \beta) e^{iz \cos \alpha \cos \beta} &= \frac{2^{2\mu+1} \Gamma^2(\mu + 1/2)}{\sqrt{2\pi z}} \\ &\times \sum_{n=0}^{\infty} \frac{i^n n!(n + \mu + 1/2)}{\Gamma(n + 2\mu + 1)} J_{n+\mu+1/2}(z) C_n^{(\mu+1/2)}(\cos \alpha) C_n^{(\mu+1/2)}(\cos \beta). \end{aligned} \quad (8.188)$$

After substituting z by $\zeta e^{-i\pi/2}$ this turns into

$$\begin{aligned} (\sin \alpha \sin \beta)^{-\mu} I_{\mu}(\zeta \sin \alpha \sin \beta) \exp(\zeta \cos \alpha \cos \beta) &= \frac{2^{2\mu+1} \Gamma^2(\mu + 1/2)}{\sqrt{2\pi \zeta}} \\ &\times \sum_{n=0}^{\infty} \frac{n!(n + \mu + 1/2)}{\Gamma(n + 2\mu + 1)} I_{n+\mu+1/2}(\zeta) C_n^{(\mu+1/2)}(\cos \alpha) C_n^{(\mu+1/2)}(\cos \beta). \end{aligned} \quad (8.189)$$

The Gegenbauer polynomials $C_n^{(\mu+1/2)}(z)$ can be expressed, for arbitrary μ , by means of Eq. (8.106) in terms of Jacobi polynomials $P_n^{(\mu, \mu)}$, and these further in terms of Legendre functions $P_{n+\mu}^{-\mu}$, using the formula

$$P_n^{(\mu, \mu)}(z) = (-2)^{\mu} \frac{(n + \mu)!}{n!} (1 - z^2)^{-\mu/2} P_{n+\mu}^{-\mu}(z). \quad (8.190)$$

Thus¹²

$$C_n^{(\mu+1/2)}(z) = \frac{\Gamma(n + 2\mu + 1) \Gamma(\mu + 1)}{\Gamma(2\mu + 1) n!} \left[\frac{1 - z^2}{4} \right]^{-\mu/2} P_{n+\mu}^{-\mu}(z). \quad (8.191)$$

We can now perform the integrations in the time-sliced path integral by means of the known continuation of the orthogonality relation (8.182) to arbitrary real values of μ :

$$\int_{-1}^1 \frac{d \cos \theta}{\sin^2 \theta} P_{n+\mu}^{-\mu}(\cos \theta) P_{n'+\mu}^{-\mu}(\cos \theta) = \frac{n!}{(n + 2\mu)!} \frac{2}{2n + 1\mu + 1} \delta_{nn'}. \quad (8.192)$$

Note that for noninteger μ , the Legendre functions $P_{n+m}^{-m}(\cos \theta)$ are no longer polynomials as in (1.421). Instead, they are defined in terms of the hypergeometric function as follows:

$$P_{\nu}^{\mu}(z) = \frac{1}{\Gamma(1 - \mu)} \left(\frac{1 + z}{1 - z} \right)^{\mu/2} F(-\nu, \nu + 1; 1 - \mu; (1 - z)/2). \quad (8.193)$$

The integral formula (8.192) is a consequence of the orthogonality of the Gegenbauer polynomials (8.104), which is applied here in the form

$$\int_{-1}^1 dz (1 - z^2)^{\mu} C_n^{(\mu+1/2)}(z) C_{n'}^{(\mu+1/2)}(z) = \delta_{nn'} \frac{\pi 2^{-2\mu} \Gamma(2\mu + 2 + n)}{n!(n + \mu) [\Gamma(\mu + 1/2)]^2}. \quad (8.194)$$

¹¹G.N. Watson, *Theory of Bessel Functions*, Cambridge University Press, 1952, Ch. 11.6, Eq. (11.9).

¹²I.S. Gradshteyn and I.M. Ryzhik, op. cit., Formula 8.936.

Using (8.189), (8.191) and (8.192), the integrals in the product (8.207) can all be performed as before, resulting in the amplitude (8.186) with the continuum limit (8.187), both valid for arbitrary real values of $m = \mu \geq 0$.

The continuation to arbitrary real values of μ has an important application: The action (8.177) of the projected motion of a particle near the surface of the sphere coincides with the action of a particle moving in the so-called Pöschl-Teller potential [5]:

$$V(\theta) = \frac{\hbar^2}{2Mr^2} \frac{s(s+1)}{\sin^2 \theta} \quad (8.195)$$

with the strength parameter $s = m - 1/2$. After the continuation of arbitrary real $m = \mu \geq 0$, the amplitude (8.187) describes this system for any potential strength. This fact will be discussed further in Chapter 14 where we develop a general method for solving a variety of nontrivial path integrals.

Note that the amplitude $(\sin \theta_b \tau_b | \sin \theta_a \tau_a)_m$ satisfies the Schrödinger equation
